CONTENTS OF VOLUME XXXIII.

EDITORIAL NOTES.

	Page.
Establishment of the States Relations Service.....	1
Review of the Office of Experiment Stations.....	2
Progress in the organization of agricultural extension work under the Smith-Lever Act.....	101
Some administrative problems being encountered.....	102
The Berkeley convention of the Association of American Agricultural Colleges and Experiment Stations.....	301
The preparation of men for teaching and research in agriculture.....	303
The effective correlation of station and extension work.....	306
Some other problems before the association.....	307
Some problems in publishing experiment station work.....	401
The practice of outside publication.....	403
The need of a systematic procedure.....	405
The element of chance in agricultural experimentation and investigation.....	601
Fourth Convention of the International Association of Dairy and Milk Inspectors.....	701

STATION PUBLICATIONS ABSTRACTED.

ALABAMA COLLEGE STATION:	
Bulletin 184, May, 1915.....	336
Bulletin 185, July, 1915.....	680, 691
Circular 32, June, 1915.....	357

	Page.
ALABAMA TUSKEGEE STATION :	
Bulletin 26, 1915.....	232
Bulletin 27, 1915.....	318
Bulletin 28.....	440
Bulletin 29, 1915.....	635
Bulletin 30, 1915.....	636
ALASKA STATIONS :	
Annual Report, 1914.....	616, 631, 632, 637, 646, 666, 680, 694, 698
ARIZONA STATION :	
Bulletin 74, February 1, 1915.....	688
Twenty-fifth Annual Report, 1914.....	19, 31, 48, 49, 57, 73, 77, 87, 94, 96
ARKANSAS STATION :	
Bulletin 121, January, 1915.....	137
Bulletin 122, February, 1915.....	142
Circular 25, February, 1915.....	86
Circular 26, February, 1915.....	91
Circular 27, February, 1915.....	95
CALIFORNIA STATION :	
Bulletin 251, April, 1915.....	24
Bulletin 252, May, 1915.....	243
Bulletin 253, May, 1915.....	286
Bulletin 254, May, 1915.....	342, 362
Bulletin 255, May, 1915.....	558
Bulletin 256, June, 1915.....	575
Bulletin 257, July, 1915.....	838

Research Bulletin 35, June, 1915.....	515

WYOMING STATION:

Index Bulletin E, March, 1915.....	299
------------------------------------	-----

UNITED STATES DEPARTMENT OF AGRICULTURE PUBLICATIONS
ABSTRACTED.

Journal of Agricultural Research:

Volume 3—

No. 6, March, 1915.....	56, 72
-------------------------	--------

Volume 4—

No. 1, April, 1915.....	107, 125, 147, 148, 149, 150, 178
No. 2, May, 1915.....	217, 234, 245, 246, 254
No. 3, June, 1915.....	323, 329, 345, 346, 351, 354, 357, 360
No. 4, July, 1915.....	610, 641, 644, 648, 650, 651, 658
No. 5, August, 1915.....	726, 742, 744, 748, 761, 762, 766

Bulletin 125, Zygadenus, or Death Camas, C. D. Marsh, A. B. Clawson, and H. Marsh.....	177
Bulletin 168, Grades for Commercial Corn, J. W. T. Duvel.....	433
Bulletin 175, Mushrooms and Other Common Fungi, Flora W. Patterson and Vera K. Charles.....	65
Bulletin 184, The Huisache Girdler, M. M. High.....	63
Bulletin 185, Bird Migration, W. W. Cooke.....	57
Bulletin 188, Importance of Thick Seeding in the Production of Milo in the San Antonio Region, S. H. Hastings.....	38

	Page.
Bulletin 189, Studies of the Codling Moth in the Central Appalachian Region, F. E. Brooks and E. B. Blakeslee.....	61
Bulletin 190, The Drainage of Irrigated Land, R. A. Hart.....	88
Bulletin 191, Demurrage Information for Farmers, G. C. White.....	91
Bulletin 192, Insects Affecting Vegetable Crops in Porto Rico, T. H. Jones..	59
Bulletin 193, The Drainage of Jefferson County, Tex., H. A. Kipp, A. G. Hall, and S. W. Frescoln.....	188
Bulletin 194, The Flow of Water in Irrigation Channels, F. C. Scobey....	183
Bulletin 195, Potato Breeding and Selection, W. Stuart.....	233
Bulletin 196, Methods Followed in the Commercial Canning of Foods, A. W. Bitting.....	210
Bulletin 197, Homemade Lime-sulphur Concentrate, E. W. Scott.....	154
Bulletin 198, Report Upon the Cypress Creek Drainage District, Desha and Chicot Counties, Ark., S. H. McCrory et al.....	288
Bulletin 199, Loss in Tonnage of Sugar Beets by Drying, H. B. Shaw.....	135
Bulletin 200, A Maggot Trap in Practical Use; An Experiment in House-fly Control, R. H. Hutchison.....	156
Bulletin 201, Native Pasture Grasses of the United States, D. Griffiths, G. L. Bidwell, and C. E. Goodrich.....	227
Bulletin 202, The Alcohol Test in Relation to Milk, S. H. Ayers and W. T. Johnson, jr.....	113
Bulletin 203, Field Studies of the Crown Gall of Sugar Beets, C. O. Townsend.....	147
Bulletin 204, Report on the Gipsy Moth Work in New England, A. F. Burgess.....	254
Bulletin 205, Eleven Important Wild Duck Foods, W. L. McAtee.....	251
Bulletin 206, The Woolgrower and the Wool Trade, F. R. Marshall and L. L. Heller.....	270
Bulletin 207, Cypress and Juniper Trees of the Rocky Mountain Region, G. B. Sudworth.....	343
Bulletin 208, Fields of Native Prickly Pear in Southern Texas, D. Griffiths..	134
Bulletin 209, Testing Grape Varieties In the Vinifera Regions of the United States, G. C. Husmann.....	538
Bulletin 210, Seed Production of Western White Pine, R. Zon.....	144
Bulletin 211, Factors Affecting Range Management in New Mexico, E. O. Wooton.....	268
Bulletin 212, Observations on the Pathology of the Jack Pine, J. R. Weir..	351
Bulletin 213, The Use of Land in Teaching Agriculture in Secondary Schools, E. Merritt.....	195
Bulletin 214, Spring Wheat in the Great Plains, E. C. Chilcott, J. S. Cole, and W. W. Burr.....	137
Bulletin 215, Composition of Corn (Maize) Meal Manufactured by Different Processes and the Influence of Composition on the Keeping Qualities, A. L. Winton et al.....	259
Bulletin 216, Cotton Warehouses: Storage Facilities Now Available in the South, R. L. Nixon.....	191
Bulletin 217, Mortality Among Waterfowl Around Great Salt Lake, Utah, A. Wetmore.....	251
Bulletin 218, Oats in the Great Plains Area, E. C. Chilcott et al.....	232
Bulletin 219, Corn in the Great Plains Area, E. C. Chilcott et al.....	231
Bulletin 220, Road Models.....	393
Bulletin 221, The Southern Corn Leaf-beetle, E. O. G. Kelly.....	358
Bulletin 222, Barley in the Great Plains Area, E. C. Chilcott et al.....	230

	Page.
Bulletin 223, Botanical Characters of the Leaves of the Date Palm Used in Distinguishing Cultivated Varieties, S. C. Mason.....	342
Bulletin 225, A System of Accounting for Cooperative Fruit Associations, G. A. Nahstoll and W. H. Kerr.....	191
Bulletin 226, The Verbena Bud Moth, D. E. Fink.....	255
Bulletin 227, Toxicity to Fungi of Various Oils and Salts, Particularly Those Used in Wood Preservation, C. J. Humphrey and Ruth M. Fleming.....	651
Bulletin 228, Effect of Frequent Cutting on the Water Requirement of Alfalfa and Its Bearing on Pasturage, L. J. Briggs and H. L. Shantz....	230
Bulletin 229, The Naval Stores Industry, A. W. Schorger and H. S. Betts..	543
Bulletin 230, Oil-mixed Portland Cement Concrete, L. W. Page.....	685
Bulletin 231, Recent Studies of the Mexican Cotton Boll Weevil, B. R. Coad.....	563
Bulletin 232, The Production of Lumber in 1913.....	344
Bulletin 233, Relation of the Arizona Wild Cotton Weevil to Cotton Planting in the Arid West, B. R. Coad.....	257
Bulletin 234, Utilization and Management of Lodgepole Pine in the Rocky Mountains, D. T. Mason.....	443
Bulletin 235, Control of Dried-fruit Insects in California, W. B. Parker....	353
Bulletin 236, A System of Accounts for Farmers' Cooperative Elevators, J. R. Humphrey and W. H. Kerr.....	192
Bulletin 237, Strawberry Supply and Distribution in 1914, W. A. Sherman, H. F. Walker, and O. W. Schleussner.....	142
Bulletin 238, Sugar Beets: Preventable Losses in Culture, H. B. Shaw....	434
Bulletin 239, The Eggplant Lace-bug, D. E. Fink.....	355
Bulletin 240, Pasteurizing Milk in Bottles and Bottling Hot Milk Pasteurized in Bulk, S. H. Ayers and W. T. Johnson, jr.....	382
Bulletin 241, Studies on Fruit Juices, H. C. Gore.....	316
Bulletin 242, Corn, Milo, and Kafr in the Southern Great Plains Area: Relation of Cultural Methods to Production, E. F. Chilcott, W. D. Griggs, and C. A. Burmeister.....	332
Bulletin 243, Cone Beetles: Injury to Sugar Pine and Western Yellow Pine, J. M. Miller.....	458
Bulletin 244, Life History of Shortleaf Pine, W. R. Mattoon.....	443
Bulletin 245, Further Experiments in the Destruction of Fly Larvæ in Horse Manure, F. C. Cook, R. H. Hutchison, and F. M. Scales.....	455
Bulletin 246, Vitrified Brick Pavements for Country Roads, V. M. Peirce and C. H. Moorefield.....	686
Bulletin 247, A Disease of Pines Caused by <i>Cronartium pyriforme</i> , G. G. Hedgcock and W. H. Long.....	448
Bulletin 248, Fleas, F. C. Bishopp.....	657
Bulletin 249, Portland Cement Concrete Pavements for Country Roads, C. H. Moorefield and J. T. Voshell.....	685
Bulletin 250, Food Plants of the Gipsy Moth in America, F. H. Mosher....	453
Bulletin 251, The Calosoma Beetle (<i>Calosoma sycophanta</i>) in New England, A. F. Burgess and C. W. Collins.....	457
Bulletin 252, Life History of the Codling Moth in Maine, E. H. Siegler and F. L. Simanton.....	559
Bulletin 253, Effect of Different Times of Plowing Small-grain Stubble in Eastern Colorado, O. J. Grace.....	332
Bulletin 254, The Sharp-headed Grain Leafhopper, E. H. Gibson.....	356

	Page.
Bulletin 255, Douglas Fir Pitch Moth, J. Brunner.....	454
Bulletin 256, Katydid Injurious to Oranges in California, J. R. Horton and C. E. Pemberton.....	451
Bulletin 257, Progress Reports of Experiments in Dust Prevention and Road Preservation, 1914.....	686
Bulletin 258, Lessons in Elementary Agriculture for Alabama Schools, E. A. Miller.....	597
Bulletin 259, Studies on Changes in the Degree of Oxidation of Arsenic in Arsenical Dipping Baths, R. M. Chapin.....	478
Bulletin 261, American Plum Borer, E. B. Blakeslee.....	454
Bulletin 262, The Parandra Borer as an Orchard Enemy, F. E. Brooks....	457
Bulletin 263, The Cranberry Rootworm, H. B. Scammell.....	456
Bulletin 264, The Violet Rove Beetle, F. H. Chittenden.....	563
Bulletin 266, Outlets and Methods of Sale for Shippers of Fruits and Vegetables, J. W. Fisher, jr., J. H. Collins, and W. A. Sherman.....	692
Bulletin 267, Methods of Wholesale Distribution of Fruits and Vegetables on Large Markets, J. H. Collins, J. W. Fisher, jr., and W. A. Sherman...	692
Bulletin 268, Crop Production in the Great Plains Area, E. C. Chilcott, J. S. Cole, and W. W. Burr.....	632
Bulletin 269, Farmers' Institute Work in the United States in 1914, and Notes on Agricultural Extension Work in Foreign Countries, J. M. Sted- man.....	698
Bulletin 270, Cereal Experiments at the Williston Station, F. R. Babcock..	633
Bulletin 273, Dispersion of Gipsy Moth Larvæ by the Wind, C. W. Col- lins.....	653
Bulletin 274, Factors Governing the Successful Shipment of Red Rasp- berries from the Puyallup Valley, H. J. Ramsey.....	642
Bulletin 277, Cotton Warehouse Construction, R. L. Nixon.....	784
Bulletin 279, Single-stalk Cotton Culture at San Antonio, R. M. Meade...	730
Bulletin 281, Correlating Agriculture with the Public School Subjects in the Northern States, C. H. Lane and F. E. Heald.....	791
Bulletin 282, Study of the Soft Resins in Sulphured and Unsulphured Hops in Cold and in Open Storage, G. A. Russell.....	709
Bulletin 284, Construction and Maintenance of Roads and Bridges from July 1, 1913, to December 31, 1914.....	889
Bulletin 286, Strength Tests of Structural Timbers Treated by Commer- cial Wood-preserving Processes, H. S. Betts and J. A. Newlin.....	845
Bulletin 287, Device for Sampling Grain, Seeds, and Other Material, E. G. Boerner.....	836
Bulletin 288, Custom Ginning as a Factor in Cotton Seed Deterioration, D. A. Saunders and P. V. Cardon.....	833
Bulletin 289, Red-clover Seed Production: Pollination Studies, J. M. Westgate et al.....	832
Bulletin 290, Rail Shipments and Distribution of Fresh Tomatoes, 1914, W. A. Sherman, P. Froehlich, and H. F. Walker.....	837
Report 107, Larvæ of the Prioninæ, F. C. Craighead.....	360
Farmers' Bulletin 637, The Chinch Bug, F. M. Webster.....	59
Farmers' Bulletin 638, Cockroaches, C. L. Marlatt.....	59
Farmers' Bulletin 659, The True Clothes Moths, C. L. Marlatt.....	62
Farmers' Bulletin 660, Weeds: How to Control Them, H. R. Cox.....	139
Farmers' Bulletin 661, A Method of Analyzing the Farm Business, E. H. Thomson and H. M. Dixon.....	91
Farmers' Bulletin 662, The Apple-tree Tent Caterpillar, A. L. Quaintance..	155

	Page.
Farmers' Bulletin 663, Drug Plants Under Cultivation, W. W. Stock-berger.....	241
Farmers' Bulletin 664, Strawberry Growing in the South, H. C. Thompson.....	47
Farmers' Bulletin 665, The Agricultural Outlook.....	93
Farmers' Bulletin 666, Foot-and-Mouth Disease, J. R. Mohler.....	84
Farmers' Bulletin 667, Breaking and Training Colts, V. G. Stambaugh.....	271
Farmers' Bulletin 668, The Squash-vine Borer, F. H. Chittenden.....	255
Farmers' Bulletin 669, Fiber Flax, F. C. Miles.....	232
Farmers' Bulletin 670, Field Mice as Farm and Orchard Pests, D. E. Lantz.....	250
Farmers' Bulletin 671, Harvest Mites or "Chiggers," F. H. Chittenden.....	258
Farmers' Bulletin 672, The Agricultural Outlook.....	192
Farmers' Bulletin 673, Irrigation Practice in Rice Growing, C. G. Haskell.....	337
Farmers' Bulletin 674, Control of the Citrus Thrips in California and Arizona, J. R. Horton.....	354
Farmers' Bulletin 675, The Roundheaded Apple-tree Borer, F. E. Brooks.....	360
Farmers' Bulletin 676, Hard Clover Seed and Its Treatment in Hulling, G. T. Harrington.....	334
Farmers' Bulletin 677, Growing Hay in the South for Market, C. V. Piper, H. B. McClure, and L. Carrier.....	332
Farmers' Bulletin 678, Growing Hard Spring Wheat, C. R. Ball and J. A. Clark.....	337
Farmers' Bulletin 679, House Flies, L. O. Howard and R. H. Hutchison.....	455
Farmers' Bulletin 681, The Silverfish; An Injurious Household Insect, C. L. Marlatt.....	459
Farmers' Bulletin 682, A Simple Trap Nest for Poultry, A. R. Lee.....	473
Farmers' Bulletin 684, Squab Raising, A. R. Lee.....	872
Farmers' Bulletin 686, Uses of Sorghum Grain, C. R. Ball and B. E. Rothgeb.....	835
Farmers' Bulletin 687, Eradication of Ferns from Pasture Lands in the Eastern United States, H. R. Cox.....	836
Farmers' Bulletin 688, The Culture of Rice in California, C. E. Chambliss and E. L. Adams.....	834
Farmers' Bulletin 689, A Plan for a Small Dairy House, E. Kelly and K. E. Parks.....	892
Program of Work of the United States Department of Agriculture, 1916.....	698
Weekly News Letter, Vol. 2, No. 51.....	674
Yearbook, 1914.....	209,
210, 219, 235, 242, 250, 261, 268, 270, 273, 274, 288, 290, 292, 294, 299	

OFFICE OF THE SECRETARY :

Circular 47, Cooperative Agricultural Extension Work.....	94
Circular 48, Marketing Maine Potatoes, C. T. More and G. V. Branch.....	40
Circular 49, Motor Vehicle Registrations and Revenues, 1914.....	189
Circular 50, Diversified Agriculture and the Relation of the Banker to the Farmer, B. Knapp.....	490
Circular 51, The Hessian Fly Situation in 1915, F. M. Webster and E. O. G. Kelly.....	455
Special [Circular], Peanut Growing in the Cotton Belt, H. C. Thompson.....	40

	Page.
BUREAU OF BIOLOGICAL SURVEY:	
North American Fauna 37, Revision of the American Marmots, A. H. Howell-----	57
BUREAU OF CHEMISTRY:	
Circular 64 (Reprint), Studies of Poultry from the Farm to the Consumer, M. E. Pennington-----	660
BUREAU OF CROP ESTIMATES:	
Monthly Crop Report—	
Volume 1—	
No. 1, May 10, 1915-----	295
No. 2, June 12, 1915-----	395
No. 3, July 15, 1915-----	594
No. 4, August 17, 1915-----	788
FOREST SERVICE:	
The Use Book; a Manual for Users of the National Forests, 1915----	541
BUREAU OF PLANT INDUSTRY:	
Document 782, Peppers, O. Powell and M. E. Creswell-----	297
Inventory 34, Inventory of Seeds and Plants Imported from January 1 to March 31, 1913-----	827
Relation of Washing to Decay in Washington Navel Oranges; Season 1914-15, C. W. Mann-----	737
Work of Belle Fourche Reclamation Project Experiment Farm, 1914, B. Aune-----	829, 837, 871
Work of the Huntley Reclamation Project Experiment Farm in 1914, D. Hansen-----	429
Work of the San Antonio Experiment Farm, 1914, S. H. Hastings---	830
Work of the Truckee-Carson Reclamation Project Experiment Farm, 1914, F. B. Headley-----	728, 735, 780
Work of the Umatilla Reclamation Project Experiment Farm in 1914, R. W. Allen-----	333, 338, 379, 390
WEATHER BUREAU:	
National Weather and Crop Bulletin 7-----	615
Circulars B and C, Instrument Division, 5. edition, Instructions for Cooperative Observers-----	118
Monthly Weather Review:	
Volume 43—	
Nos. 1-2, January-February, 1915-----	116, 117
Nos. 3-4, March-April, 1915-----	318, 319, 320
Nos. 5-6, May-June, 1915-----	715, 716
Supplement 2-----	825, 844
Climatological Data:	
Volume 1—	
No. 13-----	321
Volume 2—	
Nos. 1-2, January-February, 1915-----	19
Nos. 3-4, March-April, 1915-----	321
Nos. 5-6, May-June, 1915-----	508
The Weather Bureau [Pamphlet], H. E. Williams-----	717
OFFICE OF EXPERIMENT STATIONS:	
Report on Work and Expenditures of Agricultural Experiment Sta- tions, 1913-----	299

OFFICE OF THE SOLICITOR:		Page.

CONTENTS OF VOL. XXXIII, NO. 1.

Editorial notes:	Page.
Establishment of the States Relations Service	1
Review of the Office of Experiment Stations	2
Recent work in agricultural science	11
Notes	99

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Organic phosphorus compound of bran and hydrolysis of phytin, Anderson....	11
Proposed modification of Kober method for quantitative ammonia, Dillingham.	12
A substitute for potassium permanganate to liberate formaldehyde gas, Dixon..	12
Separating organic ammoniates of fertilizers, Jones and Anderson.....	12
Comparison of methods for total phosphoric acid in superphosphate, Peters....	13
The determination of creatin in muscle, Baumann.....	13
New apparatus for crude fiber in foods, feeding stuffs, and feces, Emmett.....	14
Estimation of acid content of flour, farina, and bread, Rammstedt.....	14
The determination of acid in flour, Kreis and Arragon.....	14
Determination of lecithin-phosphorus in macaroni, etc., Fuller.....	14
The composition of maple-sugar sand, Snell and Lochhead.....	15
Determination of benzoic acid in chopped meats, Krüger.....	15
The quantity of benzoic acid in prunes and cranberries, Radin.....	15
Determination of Prussian blue in tea, Knight.....	15
The detection of cotton-seed hulls in cotton-seed meal, Grimme.....	16
The precipitation of lactalbumin in cow's milk, Walker and Cadenhead.....	16
Comparison of methods for the estimation of fat in cream, Blanck.....	16
The alkali method for fat in ice cream and condensed milk, Bradbury.....	16
Rapid method for sodium chlorid in butter and its substitutes, Rector.....	16

	Page.
Rapid method for unsaponifiable matter in fats and oils, Pector.....	17
Method of varnish analysis, Darner.....	17
Analyses of mixed paints, Ladd and Washburn.....	17
The curing of meat and meat products on the farm, Seulke.....	17
Preliminary notes on the curing of cucumber pickles, Riley.....	17
Canning fruits and vegetables on the farm, Vincent.....	18
A practical treatise on the manufacture of vinegar, edited by Braunt.....	18
Handbook for the chemical laboratories of tanneries, Grasser.....	18
Oils of the Coniferae, I. Schorger.....	18
Chemistry of pine oil, Toch.....	19

METEOROLOGY.

Agricultural meteorology, Figueiredo.....	19
Terrestrial temperature and solar changes, Huntington.....	19
Formation of ozone in the upper atmosphere, and its influence, Pring.....	19
Climatological data for the United States by sections.....	19
Meteorological observations, Stevens.....	19
Salton Sea water, Vinson and Catlin.....	19
Rainfall of the cotton belt of the United States and its results, Wallis.....	20
Isomeric rainfall maps of the British Isles, Mill and Salter.....	20
Seasonal distribution of rainfall in the British Isles.....	20
Atlas of agricultural meteorology.—I. Droughts in European Russia, Brounov.....	20

SOILS—FERTILIZERS.

Soils of the cut and burned over areas of north Idaho, Jones and Colver.....	21
Bond County soils, Hopkins et al.....	21
Reclamation of an unproductive soil of Kaukakee marsh region, Abbott et al.....	22
Soils, Brünnich.....	22
Chemical studies of soils, Tijmstra.....	22
The sphere of adsorption phenomena in the soil, Sokolobskii.....	22
Influence of radio-activity of air on micro-organisms, Trillat and Fouassier.....	23
Studies of the microfauna of soils from rice localities, Cauda and Sangiorgi.....	23
Physiology and distribution of denitrifying thiosulphate bacteria, Gehring.....	23
The formation of leaf mold, Coville.....	24
Soil tank experiments, Collison.....	24
Fertilizer value of bat guanos of Cuba and Isle of Pines, Ageton.....	24
Utilization of septic and Imhoff tank sludges, Lipman and Burgess.....	24
Peat, Davis.....	25
[Utilization of prickly pear as a fertilizer], Johnston and Tryon.....	25
The action of liquid manure as a nitrogenous fertilizer, Schulze.....	25
The manufacture of nitrates from the atmosphere, Scott.....	25
The action of certain new nitrogenous fertilizers, Tacke.....	25
[Some effects of fertilizer mixtures containing calcium cyanamid], King.....	25
The kelp industry.....	25
The new potash deposits in Spain.....	26
Potash deposits in Catalonia.....	26
Lime in agriculture, Shutt.....	26
Ground limestone for acid soils, Barker and Collison.....	26
Gypsum, Stone.....	26
Analyses and valuations of commercial fertilizers, Cathcart et al.....	27
Fertilizer registrations, Cathcart.....	27

AGRICULTURAL BOTANY.

Applied and economic botany, Kraemer.....	27
The vegetation of Nantucket, Harshberger.....	27
The character of the tubers of <i>Batatas edulis</i> , Kamerling.....	27
The structure of clover blooms, Fominykh.....	27
Studies of <i>Campthosorus rhizophyllus</i> , Pickett.....	27
The sexuality of rust fungi, Rawitscher.....	27
Recent aspects of mutation, Gates.....	27
Growth and variation in maize, Pearl and Surface.....	28
The causes of growth in plants, III, Borowikow.....	28
Further studies on the colloidal and physical chemistry of the cell, Ruhland.....	28

	Page
Influence of ultraviolet rays on chlorophyll-containing cells, Stoklasa.....	28
The relation of chlorophyll formation to light wave length, Schmidt.....	29
A simple apparatus for the study of phototropic responses in seedlings. H. J. ...	29
Irritability as related to plasmatic conditions, Heilbrunn.....	26
Transpiration of <i>Silphium laciniatum</i> , Giddings.....	29
The physiology of germination, Müller.....	29
The germination of seeds of <i>Arisema</i> , Pickett.....	29
The longevity of submerged seeds, Shull.....	30
The assimilation of atmospheric nitrogen, Kövessi.....	30
Biochemical influence of manganese, Pugliese.....	30
Action of antimicrobial salts on respiration of plants, Palladin and G. H. Stamm.....	30
Volatile acids in fermentation products of some anaerobic bacteria, Seliber.....	30
Fatal temperatures for diastases of animal or vegetable origin, Tedoresco.....	30
Excretion of toxic substances by roots, Prianichnikov.....	31
Alterations in the forms of antagonism curves, Oterhout.....	31
The influence of X-rays on vegetation, Miège and Coupé.....	31

FIELD CROPS.

Plant breeding, Freeman and Uphof.....	31
[Field experiments], McOmie.....	31
[Field crop trials], Scott.....	31
[Field crops experiments], Garrett and Quereau.....	32
Field experiments, Woods.....	32
Experiments with farm crops in southwest Missouri, Hutchison and Douglas.....	33
Soil fertility problems, Stookey.....	33
[Cultural and fertilizer experiments], Stookey.....	33
Growing succulent feeds for fall and winter use.—I. Root crops, Stookey.....	34
Growing succulent feeds for fall and winter use.—II. [Winter crops], Stookey.....	34
Summary of results [with] cereals, 1914, Saunders et al.....	34
Report of assistant botanist, Belling.....	34
Corn, Ricks and Ames.....	34
Corn experiments, Williams and Welton.....	35
Varieties, culture, and fertilization of corn, Williams et al.....	36
Saving hay crops, Blanchard.....	38
Importance of thick seeding in production of milo, Hastings.....	38
Studies on oat breeding.—II. Selection within pure lines, Surface and Pearl.....	38
Peanut growing in the cotton belt, Thompson.....	40
Marketing Maine potatoes, More and Branch.....	40
Potato growing in western Washington, Stahl.....	40
Lime-sulphur v. Bordeaux mixture as a spray for potatoes, III, Munn.....	41
Lime-sulphur injurious to potatoes, Hall.....	41
Sudan grass, Youngblood and Conner.....	41
Turnips as a stock food, Woods.....	41
The quality of home-grown versus imported wheat, Stewart and Hirst.....	41
Yellow-berry in wheat, its cause and prevention, Headden.....	41

HORTICULTURE.

Summer treatment of greenhouse soil, Green.....	42
Onions, spinach, cauliflower, and casabas, Garcia and Rigney.....	43
[Report of the] horticultural department, Stahl.....	43
Rhubarb culture, Stahl.....	44
Recommended varieties of fruit for Idaho, Vincent and Downing.....	44
Standard varieties of tree fruits, Stahl.....	44
Studies in fruit bud formation, Gourley.....	44
Fertilizer experiments on apple trees at Highmoor Farm, Woods.....	45
Profits from spraying twenty-five Missouri orchards in 1914, Howard.....	45
Spraying and thinning notes, 1914, Gourley.....	46
Spring and summer spraying for the orchard, Rees.....	47
Spraying calendar, Vincent and Edmundson.....	47
Analyses of materials sold as insecticides and fungicides, Cathcart and Willis.....	47
Systems of training berry canes, Stahl.....	47
Harvesting the berry crops, Stahl.....	47
Varieties of strawberries and raspberries, Stahl.....	47

	Page.
Strawberry growing in the South, Thompson.....	47
Strawberry culture in Wisconsin, Moore.....	47
Fertilizer tests with red raspberries, Stahl.....	48
[Experiments with citrus seedlings in 1914], Floyd.....	48
Citrus experimental grove, Collison.....	48
[Report of the horticulturist], Lawrence.....	48
[Walnut growing in Arizona], Thornber.....	49
Tree troubles at Douglas, Arizona, Thornber.....	49

FORESTRY.

Report on progress in forestry, hunting, and fishing for 1913, Weber.....	49
Pennsylvania trees, Illick.....	49
The Cypresses, Camus.....	49
[Eucalypt yields], McOmie.....	49
The cultivation of the black locust in southeastern Indiana, Culbertson.....	50
Rubber in Brazil, Labroy and Cayla.....	50
International Rubber Congress.—Rubber book, edited by Van Hall.....	50
Chinese forest trees and timber supply, Shaw.....	50
Production and value of Irish timber, Forbes.....	50
Manuring experiments on Castleton Estate, Telok Anson, Barrowcliff et al.....	50
Report of the director of forests, Jolly.....	51

DISEASES OF PLANTS.

Plant diseases, Prillieux.....	51
Plant pathology, Tryon.....	51
Studies on Orobanche, Guéguen.....	51
Foot rot of cereals, Moreau.....	51
Smut disease in maize.....	51
Winterkilling of wheat, Schaffnit.....	51
Studies of club root. II. Methods of combating club root, Cunningham.....	52
Studies on potato anatomy, von Tiesenhausen.....	52
Diseases of potatoes, II, III, Rees.....	52
The spindling-sprout disease of potatoes, Stewart and Sirrine.....	52
Morphology and cytology of <i>Phytophthora erythroseptica</i> , Murphy.....	53
The physiology of <i>Phoma betæ</i> , Fischer.....	53
Black spot of the tomato, Darnell-Smith.....	53
Black hearted turnips, Woods.....	53
Fire blight of pear and apple, Rees.....	53
Blight resistance in pears and pear stocks, Reimer.....	53
Plum diseases, Rabaté.....	54
A parasitic disease of quinces, Blin.....	54
Experimental spraying for blackberry anthracnose, Rees.....	54
Mulberry diseases, Arnaud.....	54
A study of chlorosis in grape stocks, Marsais.....	54
Grape mildew, Ravaz.....	55
Treating citrus trees for gummosis and heart rot, Prizer.....	55
Report of plant physiologist, Floyd.....	55
Report of plant pathologist, Stevens.....	55
Die-back of citrus trees in the northern districts, Williams.....	56
Diseases of the peony, Whetzel.....	56
Diseases of oak and chestnut in Brittany, Ducomet.....	56
Chestnut disease in France, Maugin.....	56
Dissemination of ascospores of the chestnut blight fungus, Heald et al.....	56
Witches' brooms on British willows, Christy.....	56
Estimating nematodes, Baunacke.....	56

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Revision of the American marmots, Howell.....	57
Bird migration, Cooke.....	57
Entomology, Morrill.....	57
Report of the state entomologist of Connecticut for 1914, Britton.....	57
Report of entomologist, Watson.....	58
Insects affecting vegetable crops in Porto Rico, Jones.....	59

	Page.
The control of apple insects in Clinton County, Crosby and Mix.....	59
Insects destructive to grain and grain products stored, Dean.....	59
House fumigation, Woodworth.....	59
How to control the grasshoppers, Ball.....	59
Cockroaches, Marlatt.....	59
List of the Hemiptera-Heteroptera of Maine, Parshley.....	59
The chinch bug, Webster.....	59
Spraying for the grape leafhopper, Quayle.....	59
The woolly white fly (<i>Aleurothrixus</i> [<i>Alyrodes</i>] <i>howardi</i>), Watson.....	59
Recent Illinois work on the corn root aphid and its control, Forbes.....	60
The gipsy moth, Britton.....	61
The codling moth in the central Appalachian region, Brooks and Blakeslee.....	61
The spring cankerworm situation in Kansas, Dean.....	62
The true clothes moths, Marlatt.....	62
The root maggot pest, Stookey.....	62
The huisache girdler (<i>Oncideres putator</i>), High.....	63
The spotted click beetle (<i>Monocrepidius vesperlinus</i>), Egerton.....	63

FOODS—HUMAN NUTRITION.

Acidity in wheat flour, Fitz.....	64
Accidental poisoning due to flour containing barium carbonate, Hugouenq.....	64
Feterita, Summers.....	64
Some data on peanut butter, Utt.....	64
[Utilization of prickly pear as human food], Johnston and Tryon.....	64
Mushrooms and other common fungi, Patterson and Charles.....	65
Analyses of human milk, Spindler.....	65
Mother's milk and influence of calcium and phosphorus additions, Zuckmayer.....	65
What every ice cream dealer should know.....	65
The preparation of pure sucrose and dextrose caramels, Beal and Zoller.....	65
Harmful effect of certain sugar cane products, Blosser.....	65
Lime juice, McGill.....	66
Leavening agents, Hart.....	66
The blanching of canned goods, Berg.....	66
Packing tea in foil containing lead, Bords.....	66
The toxicity of caffeine, Brauer.....	66
Preservatives and other chemicals in foods: Their use and abuse, Folin.....	66
[Analyses of foods, drugs, and beverages], Kolb.....	66
Special food and drug analyses, 1914, Rose and Heimburger.....	66
Thirteenth annual report of the state food commissioner of Illinois, Jones.....	66
Fourteenth annual report of the state food commissioner of Illinois, Matthews.....	67
[Food and drug inspection and analysis], Cogswell et al.....	67
[Food analyses and pure food topics], Foust.....	67
Sixth annual report of the food and drug commissioners, Jackson et al.....	67
Fourteenth report of food and drug commissioner of South Dakota, Frary.....	67
[Pure food topics and food and drug inspection], Ladd and Johnson.....	67
Department rulings relative to food and dairy products and their labeling.....	67
The food inspector's handbook, Vacher.....	67
The commercial aspect of electric cooking and heating, Wilmshurst.....	67
Electric cooking on a large scale, Schulz.....	68
The usefulness of nickel cooking utensils, Gheorghiu.....	68
Kitchen ventilation for a modern hotel.....	68
Dollar luncheons to serve four people.....	68
Feeding of Arab soldiers, Amar.....	68
Studies of the protein minimum, Hindhede.....	68
Studies of unbalanced diets, Tachau.....	68
The influence of restricted rations on growth, Hart and McCollum.....	69
Constancy of the content of phosphorus lipoids, Mayer and Schaeffer.....	69
Constancy of the content of fatty acids and cholesterol, Terroine.....	69
Fat intoxication, Weltmann.....	69
Observations on creatin and creatinin, Shaffer.....	69
Effect of salts and other ions upon oxidative processes in the body, I, Zuntz.....	69
Experimental studies of effect of salts upon respiratory metabolism, II, Mäder.....	69
The average composition of the alveolar air, Krogh and Lindhard.....	70
Respiratory exchange with and without ventilation, Socor.....	70

	Page.
[Agricultural and domestic science instruction in high schools of Wisconsin]...	94
High school clubs in agriculture and home economics, Anderson and Parrish..	94
Boys' and girls' demonstration club work in Arkansas, Jernigan.....	95
School credit for home work, Werner.....	95
The Montana Country Life Education Association.....	95
Agriculture, Benson and Betts.....	95
Practical helps in agriculture and nature study, Jones and Fowkes.....	95
Outline of course in nature study and agriculture, Wood.....	95
Nature study and agriculture for rural schools of Texas, Taylor and Winkler..	95
Nature study and agriculture in Manitoba schools.....	95
Fights of the farmer, Snyder.....	95
The book of useful plants, Rogers.....	96
Correspondence courses in agriculture for teachers.—I, Farm plants and soils..	96

MISCELLANEOUS.

Twenty-fifth Annual Report of Arizona Station, 1914.....	96
Twenty-seventh Annual Report of Colorado Station, 1914.....	96
Annual Report of Florida Station, 1914.....	96
Twenty-seventh Annual Report of Illinois Station, 1914.....	96
Twenty-seventh Annual Report of Louisiana Stations, 1914.....	96
Finances, meteorology, index.....	96
Twenty-sixth Annual Report of Vermont Station, 1913.....	97
Twenty-seventh Annual Report of Vermont Station, 1914.....	97
Report of Western Washington Station to December 31, 1914, Linklater.....	97
Monthly bulletin of the Western Washington Substation.....	97

EXPERIMENT STATION RECORD.

VOL. XXXIII.

JULY, 1915.

No. 1.

Under the plan adopted by the last Congress for the reorganization of the Federal Department of Agriculture, the States Relations Service was formally established by Secretary Houston, and began its activities with the new fiscal year on July 1, 1915. The new organization developed upon the foundation of the Office of Experiment Stations, which it will include. In addition the cooperative demonstration work of the Department has been transferred from the Bureau of Plant Industry and joined with the extension work of the States.

The functions assigned to the new Service are first of all, as the name implies, to represent the Secretary of Agriculture in his relations with the state agricultural colleges and experiment stations under the Morrill, Hatch, Adams, and Smith-Lever Acts and acts supplementary thereto. In addition, the Service is to carry on the activities authorized by Congress for farmers' cooperative demonstration work, investigations relating to agricultural schools, farmers' institutes, the relative utility and economy of agricultural products used for food, clothing, and other uses in the home, and the maintenance of agricultural experiment stations in Alaska, Hawaii, Porto Rico, and Guam, and such other matters as the Secretary of Agriculture may designate from time to time.

To carry on these various lines of work the Service will comprise the following offices: (1) The Office of the Director of the Service, which includes the general work and administration of the Service; (2) the Office of Experiment Stations, including the relations with the State and insular experiment stations, publication of Experiment Station Record, etc.; (3) the Office of Extension Work in the South, including the farmers' cooperative demonstration work and the Smith-Lever agricultural extension work in fifteen Southern States; (4) the Office of Extension Work in the North and West, including the demonstration and extension work in the remaining States; and (5) The Office of Home Economics, including investigations relative to foods, clothing, and household equipment and management.

The work of the Service relating to agricultural instruction is to be under the immediate attention of the Director, as is also that relating to farmers' institutes and similar organizations, the latter being conducted in close cooperation with the offices of extension work. The Service will thus have jurisdiction over matters relating

to all the extension work of the Department, and those connected with the administration of the Smith-Lever Act.

With the exception of the addition of the farmers' cooperative demonstration work which, as is well known, has arisen in the Bureau of Plant Industry, and the separation of the irrigation and drainage investigations by transfer to the newly expanded Office of Public Roads and Rural Engineering, most of the duties of the Service are those which have been previously conducted by the Office of Experiment Stations. The reorganization involves no radical alterations in personnel or policy except as stated, and the Office of Experiment Stations remains as an integral part of the new and larger organization. The history of this office is coincident with that of the experiment station system in this country, and a brief review of its development and activities through a period of nearly twenty-seven years seems opportune at the present juncture.

The Office of Experiment Stations was organized in 1888 by the late Hon. Norman J. Colman, then Commissioner of Agriculture. It was established primarily as the agency of the Department in carrying out the provisions of the Hatch Act of 1887, especially Section 3 of that Act which provides, in addition to other requirements, that it shall be the duty of the Commissioner of Agriculture with reference to the new stations "to indicate from time to time such lines of inquiry as to him shall seem most important; and, in general, to furnish such advice and assistance as will best promote the purpose of this act." Specific provision was made for this work in the appropriation act approved July 18, 1888, in which \$10,000 was appropriated for the purposes enumerated in the above section, and also "to compile, edit, and publish such of the results of the experiments made under Section 2 of said Act by said experiment stations as he may deem necessary."

Even before the passage of the Hatch Act had established the principle of federal aid to the States for agricultural research, the need of a central clearing house which would aid in joining the separate agricultural colleges into a single well-united system had been foreseen by the Commissioners of Agriculture and many of the institutions themselves. The matter had been under consideration at the special conventions of the agricultural colleges and other agricultural workers held by the Department in 1872, and subsequently those in 1882 and 1883. At the convention of 1885, called specifically to consider the establishment of closer relations between the Department and other agricultural institutions, a resolution was adopted recommending the creation of a bureau or division in this Department which should be the special medium of intercommunication and exchange between the Department and the various institutions

represented. In advocacy of such an agency Commissioner Colman said in his annual report for 1885:

“For many years it has become more and more apparent that one great need of the agricultural interests of the United States is a better understanding and a more intimate relation between the several agricultural colleges and experiment stations, and a more practical cooperation between these institutions and the Department of Agriculture. . . . These agricultural colleges were severally endowed by one and the same act of Congress. They are now separately carrying on experiments at an expense of time and means, and yet without any central head through which to report and compare results with each other. . . .

“Believing that the Department of Agriculture can, if wisely conducted, become a vitalizing center for a more general cooperative effort for the promotion of agricultural science, and that the various state experiment stations should be encouraged by the most cordial cooperation on the part of this branch of the National Government, I have endeavored, with my very limited means and force, to organize a branch in this Department to take charge of the returns from these colleges and stations, and to collate and distribute the information obtained for the benefit of all interested parties. I am happy to say that the institutions alluded to warmly approve of this plan, and are aiding me with their suggestions and cooperation.”

The Hatch Act passed March 2, 1887, but did not become operative until the following year, when the appropriation under it was made.

A definite organization for the new Office was effected October 1, 1888. On this date Prof. W. O. Atwater, who had been one of the leading advocates of a national system of experiment stations, began his duties as director, retaining as well the directorship of the Connecticut Storrs Station and his professorship in chemistry in Wesleyan University. Dr. A. W. Harris, now president of Northwestern University, became assistant director of the Office, and with one clerical assistant completed its initial organization.

The general policy of the Office and many of the lines of its future work were mapped out to a large extent by Professor Atwater, and in considerable measure have been adhered to in subsequent years. Some of its proposed principal functions were outlined in the report of Commissioner Colman for 1888, as follows:

“The most immediately pressing need seems to be that of a clearing house and an exchange for the stations. The stations are widely separated; they need to know more about each other’s work; they need each other’s help, especially that which comes from the interchange of experience. Much is gained by the proper distribution of

work and by cooperation where that is feasible. As a clearing house this Office can facilitate intercommunication between the stations, collate the results of their work, and facilitate its most advantageous coordination. It can serve as an exchange or distributing point for information in two ways, negotiating between the stations and the agricultural public on the one side and between the stations and the world of science on the other.

“One of the means by which this Department can mediate between the stations and the agricultural public is the issuing of a series of farmers’ bulletins, which should collate the results of station work bearing upon special topics, and the teachings of other research, and put the whole into a form so plain that the intelligent farmer will understand it, so brief that he will read it through, and so practical that he will take it to heart. Thus while each station is distributing its own results to the farmers of its own State, this instrumentality will help to make the several stations serviceable to the agriculture of the whole country.

“As a mediator between the stations and the world of science, this branch of the Department should be in a condition to collate the results of experimental research in this country and in Europe, and publish them in convenient form for the use of the station workers and others interested in the science of agriculture. The past forty years has been a period of great and increasing activity in agricultural inquiry, especially in Europe. The mass of material accumulated is large and rapidly growing; it is mostly in foreign languages, and in costly journals, publications of learned societies, monographs, and other books, which but few of our workers have, and which with lack of leisure, but few could sufficiently utilize if they had them. Indexes of literature of given subjects and, especially, abstracts of experimental research are wanted.

“One need is a journal for the stations, to contain accounts of their current research, abstracts of similar work in this and in other countries, and other matters of mutual interest. What is wanted is a publication, properly edited, adapted to our special conditions, appearing regularly and giving the latest information, doing for workers in these lines what *Die Landwirthschaftlichen Versuchs-Stationen*, the *Centralblatt für Agriculturchemie*, and other publications do for the German stations; in short, a means to provide prompt and constant intercommunication between the stations and bring them from outside the things they want to know.

“Information is also greatly needed in regard to past work and its results. This would be probably best brought to the stations in the form of monographs on special subjects. . . . It is important to avoid going over old ground, to start where others have left off, and with the benefit of their experience.”

Of the various lines of work here suggested, the first to be taken up was that of getting into communication with the various agricultural colleges and experiment stations. One of the earliest steps was the preparation of an address list of the stations. This was soon supplemented by an organization list, showing the personnel of the institutions, such as has been issued in somewhat modified form ever since. This material, together with historical accounts of the experiment station movement, federal legislation and rulings relating thereto, and similar data, constituted Bulletin 1, issued in February, 1889. Bulletin 2 was a digest of the annual reports of the stations for 1888, while other early bulletins dealt with the organization and lines of work in progress in special lines, such as horticulture and botany, reprints of the proceedings of the annual conventions of the Association of American Agricultural Colleges and Experiment Stations, etc. In 1890 the publication was commenced of a card index of experiment station literature, now embracing over thirty-five thousand entries. The useful series of compilations of analyses and similar data was instituted in 1892 by a compilation of such data for feeding stuffs. Reference may also be made to Bulletin 180, a list of the publications of the experiment stations to June 30, 1906; the monthly list of experiment station publications, begun in 1904; and the large amount of historical and statistical data embraced in the annual reports of the Office.

The abstract journal referred to was provided in the *Experiment Station Record*, the first volume of which appeared in 1889. Thirty-two volumes of this publication have now been completed, the last two volumes of which, representing merely the last fiscal year, contain nearly eight thousand abstracts as well as editorials, special articles, and brief notes on important phases of the progress of agricultural investigation and science. In addition to comprehensive indexes for each volume, two general indexes have been issued, covering respectively Volumes I to XII and XIII to XXV. The latter index contained fully two hundred thousand separate entries.

The first farmers' bulletin was published in 1889. The series proved so popular that it was soon transferred from the Office and made a general series for the Department. Nearly seven hundred of these publications have been issued to date, many of them in very large editions and distributed by Members of Congress on a large scale. A considerable number of these farmers' bulletins have been prepared in this Office, notably the series known as Experiment Station Work, of which seventy-six numbers appeared, containing over six hundred articles, based mainly on the practical work of the experiment stations.

The Office has, indeed, from the beginning been recognized as one of the most active branches of the Department in the dissemination

of information through publications. In addition to the thirty-two volumes of the *Record*, the many farmers' bulletins, special lists, indexes, reports, etc., already referred to, nearly three hundred bulletins, mainly of a scientific and technical nature, one hundred and twenty-five circulars, and many other documents of miscellaneous nature have already appeared.

Considerable attention has been given from the first to means for bringing to public notice the work of the stations as a whole. An extensive collective exhibit of the methods and results of experiment station work was prepared for the World's Columbian Exposition in Chicago, in 1893, and a similar exhibit for most of the subsequent expositions in this country, as well as for the Paris Exposition of 1900. In connection with these expositions much bibliographical material relating to the stations has been collected and published by the Office, such as Bulletin 15, a handbook of experiment station work; Bulletin 80, an elaborate report on the history and status of each station in the United States; and Bulletin 112, a similar report on the experiment stations in foreign countries.

One of the first projects to be undertaken was the assembling of the library of station publications, now believed to be the most complete collection of these publications in existence. A collection has also been attempted of the books published by college and experiment station workers, with a view to illustrating the marked influence of these institutions in this direction.

With each succeeding year the Office has come into more intimate relations with the various experiment stations as regards the supervision of their expenditures from federal funds, and in an advisory capacity with their general management and development. An annual inspection has been made of each station since 1894. Following the passage of the Adams Act in 1906, the duties of the Office in relation to the use by the stations of the federal funds were much increased. Inasmuch as the legality of the expenditures is so largely dependent upon the character of the investigation, the supervision of the funds becomes in a large measure a supervision of the investigations and experiments as far as their character, original features, and continuity are concerned. The passage of the Smith-Lever Act in 1914 added similar duties as to the administration of funds for extension work.

The Office has also conducted negotiations between the various bureaus of the Department and the stations with reference to the large amount of cooperative work which has been undertaken, and has likewise exerted its influence through the Association of American Agricultural Colleges and Experiment Stations and a large num-

ber of other organizations devoted to various phases of agricultural science.

The establishment of the Office also enabled the Department to give to its constantly increasing multitude of correspondents definite information based on experimental inquiries in many lines not covered by its own investigations. For a considerable period a large share of its work consisted in answering inquiries, but with the extension of the work and organization of the Department such work has been largely assumed by the other bureaus.

Closely allied to the work of the Office with reference to the experiment stations have been its relationships with institutions for agricultural education. One of the first pieces of work undertaken by the Office was the preparation of a brief history of agricultural education and research in the United States for the Paris Exposition of 1889. After the passage of the Morrill Act of 1890, the Office was made the depository of the reports of the agricultural colleges to the Secretary of Agriculture; and through its close association with the Association of American Agricultural Colleges and Experiment Stations was called on to aid the rapidly growing movement for agricultural education in various ways. The director of the Office has served on the standing committee on agricultural instruction of the Association for many years, and has been dean of the Graduate School of Agriculture since its beginning in 1902.

In recent years many of its activities have been conducted through its agricultural education service, which represents the Department in its relations with agricultural colleges and schools at home and abroad. Much attention has been given to improving the courses of instruction in agriculture by reducing the various branches to sound pedagogical form, the encouragement of agricultural instruction of secondary grade, and the development of adequate graduate instruction. The work of aiding in the development of farmers' institutes was officially undertaken in 1903, when a farmers' institute specialist was appointed, and has since continued with increasing attention to the various other phases of extension work.

In addition to its general supervision of the expenditures of the experiment stations under the Hatch and Adams Acts, the Office has had in direct charge the management of the so-called insular stations. The first of these was established in Alaska in 1898, followed by the federal stations in Hawaii and Porto Rico in 1901, and that in Guam in 1908. These stations have from the start given much emphasis to special problems, the general policy having been to determine and develop the agricultural possibilities of Alaska, to diversify the agriculture of Hawaii and Porto Rico, and to restore that of Guam to its former importance. Many important results have already been se-

cured by these stations and their recommendations have effected valuable improvements in the agricultural practice of their respective localities.

In 1894 the state experiment stations were specifically authorized by Congress to include the study of the food of man in their inquiries and instructed to report their progress to this Department. An appropriation was also made of \$10,000 "to enable the Secretary of Agriculture to investigate and report upon the nutritive value of the various articles and commodities used for human food." The prosecution of this inquiry was assigned to the Office of Experiment Stations, which had already instituted work in collating information regarding the methods and results of food investigations in this country and in Europe. The enterprise subsequently became a part of the regular work of the Office and has contributed largely to the available fund of technical and popular data on nutrition, and to the introduction of studies along this line into the curricula of a large number of colleges and schools.

The purpose of the nutrition investigations has been to study the use as food of the products of farm, ranch, and garden and to bring the results obtained to the attention of housekeepers and thus help them in making the best, most rational, and most economical use of their available resources; and to provide material for the teacher, physician, and others who need accurate information on food and nutrition in their professional work. Very many questions have been studied and the results obtained have been of decided value to the producer of food supplies and to those who manufacture, handle, and market them, as well as to the housekeeper, the teacher, and the professional man.

The respiration calorimeter, an instrument of precision for measuring the total income and outgo of matter and energy in experiments with man, has been perfected, found useful for a great variety of experimental work, and extensively and profitably employed for such purposes. Later developments of this instrument are forms suited to the study of problems of vegetable physiology and other questions of interest in connection with the work of the Department.

A total of 132 nutrition publications have been issued, of which 62 are technical bulletins. The publications as a whole have been in much demand, their total distribution to the close of the fiscal year 1915 being 16,305,800 copies, of which 15,952,150 copies were farmers' bulletins.

The scope of this work was increased in 1914 to include similar studies of agricultural products in their relation to clothing and other uses in the home. This extension was brought about very largely in response to the demands of housekeepers, educators, and

others for work along these lines, in consequence of their appreciation of the value of the studies with foods already undertaken.

In 1898 Congress added further to the work of the Office by appropriating \$10,000 "for the purpose of collecting from agricultural colleges, agricultural experiment stations, and other sources . . . valuable information and data on the subject of irrigation, and publishing the same in bulletin form." This work has grown from year to year as Congress has increased the appropriations, the allotment for the past year being \$106,400. At the time the work was begun the most conspicuous need of the arid region was legislation controlling the use of water for irrigation. Largely through the efforts of this Office most of the arid States have since that time adopted comprehensive codes of water laws.

As demands for legal studies have decreased more attention has been given to engineering and agricultural improvement in irrigation practice. Local appreciation of the value of this work is evidenced by the fact that in most of the arid States either the States themselves or some of their public institutions have of late been cooperating with the Office on a dollar for dollar basis. The object of all these investigations is the best use of the water supply of the arid region, which is so limited that under the most favorable conditions only a small percentage of the arable land can be irrigated.

Previous to 1902 the Department gave no special attention to land drainage, although it has been estimated that there are in the United States approximately seventy-nine million acres of land, exclusive of tidal marshes, that can not be profitably cultivated on account of excess moisture but which could be reclaimed at a net profit of nearly \$1,600,000,000. In that year authority was given the Office in connection with its irrigation investigations to investigate the making of plans for the removal of seepage and surplus water by drainage. Subsequently the work was further extended in scope, and in 1907 was organized as a separate division of the Office.

In recent years it has included a study of the requirements of drainage in various localities and under different conditions, the collection of technical data of service to engineers and others having to do with the design of drainage improvements, and the rendering of assistance by correspondence to owners of land needing draining, by personal consultation, and occasionally by surveys with reports presenting detailed plans for the requisite improvements. Investigations have been conducted in nearly every State and approximately ten million acres have been surveyed. Of late much attention has been given to the many difficult problems in the abatement and prevention of seepage and alkali in irrigated sections.

The vast increase in scope of the original activities of the Office, and especially the addition to its duties of the special investigations in irrigation, drainage, and human nutrition, necessitated a large increase in its personnel and facilities. The initial corps of three employees had grown at the time of the reorganization to about two hundred and seventy-five, of whom over half were engaged in field work outside of Washington. The funds for its maintenance rose from \$10,000 in 1888 to \$1,930,780 in 1915.

To the student of governmental institutions, the Office of Experiment Stations has presented an example of an agency exercising chiefly advisory functions. Although charged with administrative duties toward the funds for experiment stations, it has relied less on the authority of law than on its influence in promoting the development and the well-being of the experiment station system. In accordance with the Hatch Act, it has been an integral part of that system, and in a broad sense it has sought to realize the part somewhat vaguely set forth in the clause leading to its establishment.

From the first the Office has maintained close and sympathetic relations with the stations throughout the entire country, studying their conditions and problems at first hand. From these studies and the history of investigation, standards of work and of organization have been set forth, and the effort has been made to stand between the stations and influences which did not represent their best interests in the long run. The fact that this relationship has been so largely voluntary and informal, and in a sense a personal one, rather than a strictly official one operating under force of law, has shown the mutual confidence and understanding which have developed through these twenty-seven years. Stimulation and assistance rather than restraint or attempt at centralized direction has been the guiding motive at all times.

The same principles have very largely determined the course of action in the special lines of service which have been added to its more general duties from time to time, and this will continue without interruption in the enlarged field of the States Relations Service.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Concerning the organic phosphorus compound of wheat bran and the hydrolysis of phytin, R. J. ANDERSON (*New York State Sta. Tech. Bul. 40 (1915), pp. 31*).—"This bulletin contains reports of investigations concerning (1) the nature and composition of the principal organic phosphoric acid isolated from 0.2 per cent hydrochloric acid extract of wheat bran, (2) the products formed from phytin by the action of the enzym phytase contained in wheat bran, (3) the hydrolysis of the organic phosphorus compound of wheat bran in different solvents, and (4) the nature and composition of the organic phosphorus compound of wheat bran when isolated from solvents which destroy the enzym phytase.

"It has been shown in previous reports [E. S. R., 28, p. 17] that the organic phosphorus compounds isolated from 0.2 per cent hydrochloric acid extracts of wheat bran differ in composition from phytin and phytic acid or inosit hexaphosphoric acid. It has also been shown [E. S. R., 32, p. 17] that the above substance is not a homogeneous compound but that it can be separated into several fractions which differ in composition.

"The first part of this bulletin describes the further separation of these compounds and the isolation of a new organic phosphoric acid, inosit triphosphoric acid, as a crystalline strychnin salt from the water-insoluble portion of the acid barium salts. The neutral barium inosit triphosphate, $C_6H_{12}O_{15}P_3Ba_3$, was prepared from the crystalline strychnin salt. It was a white amorphous powder. The free inosit triphosphoric acid, $C_6H_{12}O_{15}P_3$, was prepared from the barium salt, and it was obtained as a noncrystallizable sirup. The reactions of inosit triphosphoric acid differ in several particulars from those of phytic acid or inosit hexaphosphoric acid, but like the latter it decomposes, when heated in a sealed tube with dilute sulphuric acid, into inosit and phosphoric acid.

"The chief products of the hydrolysis of phytin by the phytase in wheat bran are inorganic phosphoric acid and certain intermediate compounds apparently consisting of inosit tri-, di-, and monophosphoric acids. These intermediate substances are identical with the compounds which we have previously isolated from 0.2 per cent hydrochloric acid extracts of wheat bran. A portion of the phytin was completely hydrolyzed by the action of the enzym into phosphoric acid and inosit because the solution was found to contain some free inosit. All of the phytin was partially hydrolyzed since the final reaction mixture did not contain any unchanged inosit hexaphosphoric acid.

"The results herein reported amplify and confirm the experiments of Suzuki, Yoshimura, and Takaishi [E. S. R., 19, p. 966], and of Plimmer [E. S. R., 29, p. 166], concerning the presence of the enzym 'phytase' in wheat bran which is capable of hydrolyzing phytin with the production of inorganic phosphoric acid. The maximum activity of the enzym has been shown to occur in the presence of 0.1 per cent hydrochloric acid and 0.2 per cent acetic acid. With increasing concentration of the hydrochloric acid the activity rapidly diminishes,

and with 0.5 per cent hydrochloric acid there is practically no hydrolysis of the organic phosphorus. The enzym is destroyed by boiling water and by boiling 0.2 per cent hydrochloric acid. It is also destroyed by a short exposure to 0.5 per cent hydrochloric acid and to 0.25 per cent ammonia. It is shown that wheat bran normally contains about 0.1 per cent of inorganic phosphorus, which is equal to about 11 per cent of the total soluble phosphorus.

"By digesting wheat bran in 1 per cent hydrochloric acid, which is sufficiently strong to destroy the enzym phytase, it is possible to isolate from the extract crystalline barium salts of the following composition:

These salts are identical with the tribarium phytate and heptabarium phytate obtained from oats, corn, cotton-seed meal, and commercial phytin. All of these materials contain, therefore, the same organic phosphorus compound, viz, phytic acid or inosit hexaphosphoric acid, $\text{C}_6\text{H}_{12}\text{O}_{24}\text{P}_6$."

A proposed modification of the Kober method for quantitative ammonia distillation by aeration, F. L. DILLINGHAM (*Jour. Amer. Chem. Soc.*, 36 (1914), No. 6, pp. 1310-1312).—The value of the Kober and Graves method^a for determining ammonia was studied with ammonium sulphate. As a pump drawing only 360 liters of air per hour was available, more aeration, as recommended by the originators of the method, was used. "A large number of determinations were made, and in no case could all the ammonia be recovered by this method of aeration. In each case quantities of ammonia varying, in round numbers, from 3 to 15 per cent were found to be retained in the residual liquid in the Kjeldahl flask. . . .

"This failure to recover all of the ammonia, by aeration alone, suggested a modification of the method, which has been carefully tried out and which it is desired to offer. The modification consists in utilizing the heat of neutralization and in heating the liquid in the Kjeldahl flask over a low flame during the entire period of aeration. Pieces of zinc may be added to prevent bumping. It is well also to use a larger amount of water than the original method calls for. The outlet tube of the Kjeldahl flask should be provided with a glass trap to prevent carrying over of the sodium hydroxid. This modification will allow all of the ammonia to be recovered from ammonia sulphate in one and one-half hours. The liquid in the absorption bottle naturally becomes quite hot from the steam, but no loss of ammonia occurs, provided the standard acid is present in excess. When the absorption of ammonia is complete the absorption bottle may be cooled and the excess of standard acid titrated in the usual manner."

A substitute for potassium permanganate to liberate formaldehyde gas from a water solution, S. G. DIXON (*Jour. Amer. Med. Assoc.*, 63 (1914), No. 12, p. 1025).—The substitute proposed is sodium dichromate. The formaldehyde is mixed with sulphuric acid and kept as a stock solution.

A procedure for separating organic ammoniates from the mineral portion of commercial fertilizers, C. H. JONES and G. F. ANDERSON (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 7, pp. 580, 581).—The method consists of drying from 100 to 600 gm. of materials, preferably unground, at a temperature of not over 170° F., cooling and weighing, and dropping the sample in 25 to 50 gm. portions into a beaker nearly filled with carbon tetrachlorid. The mixture is then stirred, allowed to settle, the portion which floats skimmed off with an ordinary tablespoon, and the floats placed on a dry filter. The process is continued until the entire sample has been treated, using another beaker if neces-

^aJour. Amer. Chem. Soc., 35 (1913), p. 1594.

sary. The filters containing the organic portions of the fertilizer are dried in an air bath, cooled, weighed, and preserved for microscopical and chemical analyses.

The above procedure has been subjected to extensive use on many commercial fertilizer and crude nitrogenous stock samples. It was found that the following materials float on carbon tetrachlorid: Dried blood, fish, tankage, hoof meal, horn meal, leather, kanona tankage, morocco clippings, azotin, cottonseed meal, castor meal, castor pomace, beet refuse compound, nitrogenous manure, casein, peat, garbage tankage, tartar pomace, mowrah meal, rape meal, soy-bean meal, wheat gluten, tobacco stems, fillerine (partly), and cinders (certain types). Ground bone, nitrate of lime, cyanamid, grape pomace, aluminum nitrid, nitrate of soda, sulphate of ammonia, acid phosphate, rock phosphate, basic slag, dissolved bone black, animal charcoal, muriate and sulphate of potash, and kainit sink in carbon tetrachlorid.

A table is given showing the results obtained by the chemical analysis of the floats, including the determination of water insoluble nitrogen by the alkaline permanganate method (E. S. R., 23, p. 705) and also the finding obtained by visual inspections. The results show large variations in the nitrogen content of the mixtures which contribute to furnish the organic nitrogen found in commercial fertilizers. The water insoluble nitrogen indicates similar ranges.

The inorganic portions of the samples were also tested as regards their insoluble nitrogen content and its activity. The activity noted compared favorably with that shown by the organic (float) portion.

A classification for organic nitrogen activity as determined by the alkaline permanganate method is presented. The method may be used for other purposes also.

Comparison of a few methods for total phosphoric acid in superphosphate, C. A. PETERS (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 1, pp. 39, 40).—These data were taken from a thesis presented at the Massachusetts Agricultural College by A. G. Weigel, and consist of the results of a comparative study of a superphosphate homemade from ground rock. The results confirmed previous knowledge, indicating that "the official gravimetric method of determining total phosphoric acid gives high results when phosphoric acid is determined in superphosphate without evaporation of the solution to dryness on a steam bath to remove silica. Several methods other than the official gravimetric give equally good results in half the time."

The determination of creatin in muscle, L. BAUMANN (*Jour. Biol. Chem.*, 17 (1914), No. 1, pp. 15-17).—Many of the methods proposed in the literature for determining the creatin in flesh and blood are tedious and time-consuming. A method which follows gives results that are within the limits of experimental error.

"Fifty gm. of hashed muscle is weighed into a round bottom, short-necked Jena flask; to this 125 cc. of 5 times normal sulphuric acid and a few chips of unglazed porcelain are added and the whole boiled for three hours under a reflux condenser. At the end of this time the muscle is disintegrated. The solution is now filtered quantitatively through a 15 cm. filter paper into a 250 cc. volumetric flask (the volume of the sulphuric acid and the dilution being proportional to the weight of muscle used for analysis), the residue (less than 2 gm. of dry material) is washed thoroughly with distilled water, the fluid is cooled, and the flask filled to the mark.

"Twenty cc. of the claret-colored extract is pipetted into a small porcelain disk (8.5 cm. in diameter) and 18 cc. of 10 per cent sodium hydrate is added while stirring. The partially neutralized fluid is then evaporated on the water

bath to about 10 cc. and transferred quantitatively to a 50 cc. volumetric flask containing 30 cc. of saturated aqueous picric acid solution (the solid particles adhering to the sides of the dish are of no consequence provided the washing has been thorough). The flask is filled to the mark with distilled water when its contents have reached the proper temperature, shaken vigorously, then filtered through a dry filter paper. To 25 cc. of the clear filtrate 6 cc. of the 10 per cent sodium hydrate is added, and the creatinin determined colorimetrically according to Folin, allowing 10 minutes for the color to develop. The standard is a creatinin solution containing about 7 mg. of creatinin per 10 cc. of solution. It may easily be prepared by heating pure anhydrous creatin (about 80 mg.) with 50 cc. of 5 times normal sulphuric acid for 3 hours under a reflux condenser, then diluting at once in a volumetric flask to 100 cc. The titer of this solution remains constant for months."

A new apparatus for determining crude fiber in foods, feeding stuffs, and feces, A. D. EMMETT (*Abs. in Science, n. ser., 39 (1914), No. 1017, p. 957*).—It is often very difficult in making crude fiber determinations to transfer the last portions of the insoluble residue from the flask to the Gooch crucible or funnels. The use of a beaker instead of a flask has many advantages, and accordingly a device was developed which makes this possible.

"It consists of a specially constructed glass cone and rubber ring which prevents appreciable loss of water vapor during the boiling and thereby any increase in the concentration of the acid and alkali solutions. The inverted cone is attached to a Hopkins condenser with rubber tubing and the ring is snapped on the lower edge of the cone. The condenser, cone, and ring are then lowered over a 400 cc. lipless beaker and adjusted until the connection between the rubber ring and beaker is tight. The entire apparatus is fastened in place by the clamp which holds the condenser. The glass cone is provided with a side-tube attachment which is so constructed that when air is drawn through the apparatus gently the tendency to foam is greatly retarded."

The estimation of the acid content of flour, farina, and bread, with especial reference to bacterial and enzym action, O. RAMMSTEDT (*Ztschr. Angew. Chem., 26 (1913), No. 91, Aufsatzteil, pp. 677-680*).—In some work with maize and malted maize products the author concluded that the acidity determinations made by the methods of Kreis-Arragon (*E. S. R., 12, p. 823*), Planchon, Schindler, and Hilger and Günther were unsatisfactory. The least satisfactory results were obtained with the last-named method. A method was therefore devised which is a combination of the Kreis-Arragon and Lehmann methods and which excludes the influence of bacteria and enzymes.

The determination of acid in flour, H. KREIS and C. ARRAGON (*Ztschr. Angew. Chem., 27 (1914), No. 16, Aufsatzteil, p. 120; abs. in Chem. Ztg., 38 (1914), No. 35, Repert., p. 157*).—The opinion of Rammstedt (see above) that the Kreis-Arragon method gives results which are too high on account of the enzymes and bacteria, was not found tenable by the experimental data secured. On the other hand, it was found that in handling the residue with alcohol according to Rammstedt's recommendation an amount of acid remains behind which is equivalent to the differences observed by Rammstedt between the two methods.

The determination of lecithin-phosphorus in macaroni and farinaceous articles, H. C. FULLER (*Abs. in Science, n. ser., 39 (1914), No. 1017, p. 952*).—"The macaroni is thoroughly softened with hot water, the mass treated with a large excess of alcohol, the liquid filtered, and the solid substance treated with further portions of alcohol; the combined alcoholic solutions are evaporated and the residue extracted with ether, which dissolves the lecithin. Phosphoric

acid is determined in the latter by ignition [with] calcium acetate and finishing in the usual way with ammonium molybdate and magnesium mixture."

The analysis of maple products.—IV, The composition of maple sugar sand, J. F. SNELL and A. G. LOCHHEAD (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 301, 302).—In this investigation analyses of six samples of washed air-dried Quebec maple sand are reported. "This material contains from 65 to 80 per cent of normal calcium malate, from 6 to 18.5 per cent of silica, minor quantities of manganese, magnesium, and phosphorus, traces of iron, and from 10 to 17 per cent of undetermined material." See also a note by Warren (*E. S. R.*, 25, p. 803).

Determination of benzoic acid in chopped meats, A. KRÜGER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 26 (1913), No. 1, pp. 12-20; *abs. in Chem. Ztg.*, 38 (1914), No. 44, *Repert.*, p. 203).—The procedure is as follows:

Dissolve 50 gm. of the chopped meat in a round-bottomed, one-half liter flask with 45 cc. of 70 per cent sulphuric acid by heating gently and then distill with steam, using precaution that not more 500 cc. is obtained. Then filter the distillate, make slightly alkaline, evaporate to a small bulk in a 100 cc. dish, and treat with a saturated solution of potassium permanganate until a permanent red color remains. Remove the excess of permanganate with sodium sulphite solution and condense the solution to a bulk of 10 cc. After cooling, place in a cylindrical separatory funnel, acidify, and rinse the evaporating dish with sodium sulphite solution and sulphuric acid. Then shake the benzoic acid solution, which should amount to from 15 to 20 cc., several times with ether-petroleum ether, wash the combined ethereal solution several times with 3 cc. of water, and shake with a little (as much as will go on the tip of a knife) powdered gum tragacanth. Allow the ethereal solution to evaporate spontaneously in a weighed dish, dry the residue over soda lime, and weigh. As a control the residue is dissolved in a little neutralized alcohol and titrated, or any benzoic acid still present may be isolated by sublimation in the Polenske apparatus (*E. S. R.*, 27, p. 715).

A shorter method consists in shaking out the benzoic acid from the steam distillate with several portions of benzol containing equivalent amounts of soda solution. The extracts must also be treated with potassium permanganate to remove the fatty acids.

A note on the quantity of benzoic acid contained in prunes and cranberries, M. J. RADIN (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 6, p. 518).—For the estimation of benzoic acid Krüger's method was employed with a charge of 50 gm. of fruit. From several duplicate analyses in each instance it was found that prunes, as obtained in the market, contained approximately 0.05 per cent benzoic acid and cranberries 0.06 per cent.

"These results were furnished from the weight of sublimed benzoic acid and by titration, the data in each instance agreeing closely."

Determination of Prussian blue in tea, G. W. KNIGHT (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 11, pp. 909, 910).—The method consists of decomposing the Prussian blue in the tea with 85 per cent phosphoric acid and collecting the hydrocyanic acid in a 10 per cent sodium hydroxid solution. The hydrocyanic acid is then reconverted into Prussian blue and weighed as such. "By means of it one part in 200,000, and sometimes even one part in 300,000, can be detected. A man inexperienced in the manipulation can run four determinations in a day easily, and doubtless with experience could run many more. Two operators working independently on the same sample obtained 0.0019 and 0.0016 per cent of Prussian blue."

Several samples of uncolored China and Japan teas were examined by the method, but no Prussian blue was found.

The detection of cotton-seed hulls in cotton-seed meal, C. GRIMME (*Chem. Ztg.*, 38 (1914), No. 13, pp. 137-139, fig. 1).—It is stated that the difficulties encountered in the Fraps method (E. S. R., 20, p. 908) may be obviated if 2 gm. of the meal after being freed from fat is digested for 30 minutes from the time of boiling with 200 cc. of a 1 per cent hydrochloric acid solution, diluted to 1,000 cc. with hot water and filtered through asbestos. The residue on the filter is washed acid-free with hot water, three times with alcohol, and once with ether, dried at from 105 to 110° C. to constant weight, ignited, and the amount of ash deducted from the first weighing. The percentage of

hulls is calculated by the formula $x = \frac{(y-11) 100}{59}$ in which y represents the amount of ash-free residue. The results agree well with those given by the Fraps method.

Note on the precipitation of lactalbumin in cow's milk, W. O. WALKER and A. F. G. CADENHEAD (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 7, pp. 573, 574).—The official method for estimating lactalbumin in milk, i. e., precipitation with a 0.3 per cent acetic acid solution from a neutral solution from which casein has been removed, was found unsatisfactory.

Sebelien's method^a gave more satisfactory and uniform results and was quite as convenient, both from the standpoint of time and manipulation. The reagent, which was Almen's, was composed of 4 gm. of nitrogen-free tannic acid, 190 cc. of 50 per cent alcohol, and 8 cc. of 25 per cent acetic acid. The best results were obtained with from 10 to 12 cc. of the reagent for a 10 gm. sample of milk. "The clear filtrate, with washings from the casein—which was precipitated according to the official method—was neutralized with sodium hydroxid with the addition of a few drops of phenolphthalein. The pink color was then discharged with one drop of 10 per cent acetic acid, the filtrate, about 200 to 250 cc. in volume, was heated to 40-45° C., and the reagent added, the mixture stirred continually for two minutes and then allowed to stand for half an hour before filtering, when the albumin was precipitated in a very fine flocculent form. When filtered immediately after precipitation, some of the precipitate invariably passed through the paper. The precipitate and the paper was then treated according to the official Kjeldahl-Gunning method, the nitrogen determined, and the result multiplied by 6.34 for the albumin. The protein in the filtrate from the above operation was determined in each case and was found to show an average of 0.1 per cent."

Comparison of methods for the estimation of fat in cream with special reference to Sichler's "alcohol sin-acid" method, E. BLANCK (*Milchw. Zentbl.*, 43 (1914), No. 12, pp. 316-325).—The Sichler alcohol sin-acid method (E. S. R., 16, p. 506) gave good results, which agreed with those yielded by the Gerber and Vieth methods. The results by the Röse-Gottlieb method with the same milks were slightly lower.

The alkali method for the determination of fat in ice cream and condensed milk, C. M. BRADBURY (*Va. Dairy and Food Div. Circ.* 42 (1914), pp. 4).—An adaptation of the Short method^b for determining fat in milk and cream to the determination of fat in ice cream and condensed milk.

A rapid method for the determination of sodium chlorid in butter and its substitutes, T. M. RECTOR (*Abs. in Science, n. ser.*, 39 (1914), No. 1017, p. 952).—Sodium chlorid is determined by titration with silver nitrate with a chromate indicator, in a water solution of a weighed sample of butter in the presence of

^a Hoppe-Seyler's Ztschr. Physiol. Chem., 13 (1889) No. 1-2, pp. 135-180.

^b Wisconsin Sta. Bul. 16 (1888), pp. 14, pl. 1.

the butter fat. Some results are given to show that the fat does not interfere with the accuracy of the method.

A rapid method for the determination of unsaponifiable matter in fats and oils, T. M. RECTON (*Abs. in Science, n. ser., 39 (1914), No. 1017, p. 952*).—“The sample is saponified in the usual manner and the alcoholic soap solution diluted to an alcohol content of 55 per cent. The solution is then extracted with light petroleum spirit, the solvent evaporated, and the residue dried in vacuo and weighed.”

Method of varnish analysis, R. W. DARNER (*North Dakota Sta. Paint Bul., 1 (1915), No. 6, pp. 108-111*).—“The analysis of oil varnishes is one of great difficulty, and it is almost impossible with the present methods in use (McIlhiney's, Scott's, and Twitchel's) for separation of gum and oil to get better than an approximate estimate of the ingredients in a varnish.” The following method is suggested for long oil varnishes:

“Three to four gm. of varnish are spread out on an Adams filter coil which has been dried and weighed along with an extractive thimble. The coils absorb water rapidly, and for this reason the coils and thimble must be weighed in a weighing bottle. The varnish is best weighed and added to the coil from a dropping bottle. The coil is then held in the mouth of a 300 cc. weighed Erlenmeyer flask, and 100 cc. of petroleum ether, 0.67 specific gravity, added slowly. A large percentage of the varnish will be washed out of the coil by this treatment. The coil is then placed in the extraction thimble and extracted for 36 hours [in a Caldwell extractor with the bottom cut out], or until extraction is complete, when 150 cc. of petroleum ether, 0.67 specific gravity, is added to the flask and the flask cooled to 3° C., until the gums settle and the liquid is clear.

“The liquid containing the oils and rosin is poured off the gums and the flask washed several times with petroleum ether and the washings added to the original petroleum ether extract. The Erlenmeyer flask and thimble are then dried at 105°, to constant weight. The increase in weight of the flask and thimble minus the weight of the metallic driers represents the weight of hard gums in the varnish. The extract from the gums is freed of the petroleum ether, saponified with half-normal alcoholic potash, and the unsaponifiable matter extracted with ether. The rosin and fatty acids are then released with half-normal hydrochloric acid and extracted with ether. The acids are then freed of the ether and the rosin determined by Twitchel's method.”

Some results of tests with the method are included.

Analyses of mixed paints, E. F. LADD and W. F. WASHBURN (*North Dakota Sta. Paint Bul., 1 (1915), No. 6, pp. 85-108*).—Analyses are reported and discussed of about 70 paints, the results being interpreted in the light of the paint law of North Dakota.

The curing of meat and meat products on the farm, K. J. SEULKE (*New York Cornell Sta. Circ. 27 (1915), pp. 13*).—This circular gives practical directions for keeping fresh meat, curing meat, and the preparation of meat products (sausage, lard, head-cheese, blood pudding, etc.) on the farm.

Preliminary notes on the curing of cucumber pickles, H. N. RILEY (*Abs. in Science, n. ser., 39 (1914), No. 1017, p. 954*).—“The activities manifest in a curing tank of cucumber pickles seem all to depend upon the growth of certain bacteria, known as ‘lactic-acid bacteria.’ These seem to govern the rate of fermentation, or giving off of gas, and the production of acid. The rate of fermentation mechanically governs the rate of absorption of salt, which is also influenced, to some extent, by the size of the pickle. The growth of mold and yeast seems destructive, as they destroy the acid which is the principal keeping factor in the brine.”

Canning fruits and vegetables on the farm, C. C. VINCENT (*Idaho Sta. Bul.* 82 (1915), pp. 24, figs. 6).—The purpose of this bulletin is to demonstrate to the farmers of Idaho how they can increase the earning capacity of their farms and orchards through the cannery. The subject is dealt with under the following headings: Plan of work, equipment, accessories, labels, labor, crops for canning, steps involved in handling products, directions for canning fruits and vegetables, quality of canned products, cost of canning, and profits.

A practical treatise on the manufacture of vinegar, edited by W. T. BRANNT (*Philadelphia: H. C. Baird & Co., 1914, 3. ed., rev., pp. XXIV+543, figs. 101*).—This work has been largely rewritten. In addition to a detailed description of the manufacture of vinegar, special consideration is given to wood vinegar and other by-products obtained in the destructive distillation of wood; the manufacture of cider and fruit wines; the preservation of fruits and vegetables; and the preparation of fruit butters, jellies, marmalades, pickles, and mustards. The preservation of meat, fish, and eggs is also given consideration.

Handbook for the chemical laboratories of tanneries, G. GRASSER (*Handbuch für Gerberei-chemische Laboratorien. Leipzig: Schulze & Co., 1914, XIII+395, figs. 49*).—This book, intended for tanning chemists and those concerned in the examination of tannery products, is divided into a general and special part. The general part has to do with the examination of acids and salts, dyes, organic preparations of formaldehyde, glycerin, blood albumin, mineral oil, oils, fats, and waxes, soaps, resins, coal-tar dyes, and natural-plant dyes. The special part has to do with the examination of water and sewage, chemistry of tanning materials and their examinations (including tanning materials), examination of leathers tanned by various methods, chemical control of the tannery, and the equipment of a chemical laboratory for the tannery.

Oils of the Coniferæ.—I, The leaf and twig oils of Cuban and long-leaf pines and the cone oil of long-leaf pine, A. W. SCHORGER (*Jour. Indus. and Engin Chem., 6 (1914), No. 9, pp. 723-727, figs. 5*).—Data relative to the composition of oils and their distillation are given at the beginning of the article.

The several oils of the two species examined were practically identical in composition, as shown below. "The combined borneol in the leaf and twig oil of the Cuban pine probably occurs as the esters of caproic and caprylic acids; that in the leaf oil of long-leaf pine as the esters of caprylic, heptoic, and caproic acids.

"The rotation of the cadinene as given must be accepted with certain reservations. While the sesquiterpene fractions were *d*-rotatory, their dihydrochlorids were all *l*-rotatory. The only oil containing *d*-rotatory cadinene whose dihydrochlorid was likewise *d*-rotatory, as recorded in the literature, is that of Atlas cedar and possibly also West Indian sandalwood oil.

"In Cuban pine the percentage composition of the leaf and twig oils is as follows: Furfurol trace; *l*- α -pinene 4 per cent; *l*-camphene 10; *l*- β -pinene 35 to 36; dipentene 8; bornyl ester (as acetate) 3.5; free alcohol (as *l*-borneol) 11.4; *d*-cadinene 18 to 19; and losses by polymerization, etc., 9 per cent. In long-leaf pine the leaf and twig, leaf, and cone oils contain, respectively, furfurol trace; *l*-camphene 13 to 14, 12 to 13 and 12 per cent; *l*- β -pinene 44, 50, and 25; dipentene 5, 5, and 6 to 7; bornyl ester (as acetate) 2.4, 2, and 1.4; free alcohol (as *l*-borneol) 10, 9.8, and 7.6; *d*-cadinene 10 to 11, 11, and 1 to 2; and losses by polymerization, etc., 6, 7.5, and 6.5 per cent. The leaf and twig and leaf oil of long-leaf pine contain 8 to 9 and 2 per cent *l*- α -pinene respectively, while cone oil contains 39 to 40 per cent *d*- α -pinene."

Chemistry of pine oil, M. TOCH (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 9, pp. 720-723, fig. 1).—A discussion of the various uses to which pine oil can be put and its production and chemistry. Analyses are included.

METEOROLOGY.

Agricultural meteorology, F. E. DE A. FIGUEIREDO (*Rev. Agron. [Portugal]*, 10 (1914), No. 5-8, pp. 241-247, fig. 1).—The observations which are especially needed from the agricultural standpoint are indicated.

Terrestrial temperature and solar changes, E. HUNTINGTON (*Bul. Amer. Geogr. Soc.*, 47 (1915), No. 3, pp. 184-189, figs. 2).—This is a critical review of Köppen's views regarding the relation of temperature changes to the sun-spot cycle and Arctowski's pleion and antipleion theory of temperature variations (E. S. R., 31, p. 717).

The formation of ozone in the upper atmosphere, and its influence on the optical properties of the sky, J. N. PRING (*Sci. Prog. Twentieth Cent.*, 9 (1915), No. 35, pp. 448-470, figs. 2).—This article discusses some factors which determine the optical properties of the atmosphere, chemical determination of constituents of the atmosphere, the action of ultraviolet light on air, the determination of ozone in the atmosphere at high altitudes, and the influence of ozone on the nature of light from the sky.

It is stated that "the optical properties of the atmosphere must lie in the precise determination of the presence of such bodies as ozone, hydrogen peroxid, and nitrogen peroxid," and methods for such determinations are described. Although the methods used were designed to detect very minute amounts of the substances named, they failed to show the presence of appreciable amounts of oxids of nitrogen or hydrogen peroxid resulting from the action of ultraviolet light on air, and they also failed to show the presence of detectable amounts of these substances in the air from high altitudes.

While the tests do not preclude the possibility of the formation of these substances they show that the quantity formed is negligibly small when compared with ozone.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 2 (1915), Nos. 1, pp. 246, pls. 2, figs. 7; 2, pp. 234, pls. 2, figs. 7).—These volumes contain, respectively, brief summaries and detailed tabular statements of climatological data for each State for January and February, 1915.

Meteorological observations, J. S. STEVENS (*Maine Sta. Bul.* 234 (1914), pp. 295, 296).—A monthly and annual summary of observations at the University of Maine on temperature, precipitation, cloudiness, and wind movement during 1914 is given. The mean temperature for the year was 43.35° F., as compared with an average of 42.66° for 46 years; the precipitation was 35.04 in., as compared with an average annual precipitation of 42.75 in. for 46 years; the snowfall was 66.5 in., as compared with 88.19 in. as the average of 46 years; the number of clear days was 204; the number of cloudy days 97; the number of rainy days was 78; and the total movement of wind was 48,809 miles.

Salton Sea water, A. E. VINSON and C. N. CATLIN (*Arizona Sta. Rpt.* 1914, pp. 364-366).—This is the eighth annual report on the composition of Salton Sea water (E. S. R., 32, p. 511), comparing analyses of samples collected June 12, 1914, with previous analyses.

During the 359 days from June 18, 1913, to June 12, 1914, the total solids increased from 1,002.56 to 1,179.6 parts per 100,000, an increase of 17.5 per cent. The construction of the total saline matter has been fairly regular during each

year of the period of observation. "The percentages of concentration for the separate constituents, however, show some variation from the general rate of concentration, due, undoubtedly, to the disturbing effects of drainage and seepage water received by the lake. Three constituents—calcium, potassium, and carbonic acid—are showing variations clearly not due to these causes. Calcium and carbonates, as in previous years, have not concentrated as much as the other constituents, carbonates again showing an actual decrease. It is now well established that this loss of calcium carbonate is due to the formation of new travertines similar to those formed when the ancient Salton Sea dried up. Potassium, however, instead of decreasing, has concentrated this year in about the same ratio as the other constituents. This may be accounted for in part by the apparent decrease in animal and vegetable organisms in the water."

The rainfall of the cotton belt of the United States and its results, B. C. WALLIS (*Scot. Geogr. Mag.*, 31 (1915), No. 2, pp. 71-79, figs. 5).—This is an account of a study similar to that of the rainfall conditions of the northeastern United States, which has already been noted (E. S. R., 32, p. 119).

It is shown that the rainfall of the cotton belt varies widely, the average annual rainfall being 31 in. in the west and 54 in. in the southeast. There is apparently a direct relation between rainfall and temperature, an average low-temperature meaning, as a rule, a small amount of precipitation. Correlating rainfall with crop growth, the conclusion is reached "that the best conditions for growing cotton occur about latitude 32° N. in an area where the total annual rainfall is about 50 in. per annum, where the temperature is normal and therefore almost entirely a function of the latitude, and where the crop rainfall depends upon the rising temperature and upon the slackening effect of oceanic influences, so that an average rainfall of 20 in. can readily be obtained during the five or six months required for the growth of the cotton plant."

The relation of rainfall to other crops grown in the cotton belt is also briefly considered.

Isomeric rainfall maps of the British Isles, H. R. MILL and C. SALTER (*Quart. Jour. Roy. Met. Soc.* [London], 41 (1915), No. 173, pp. 1-44, figs. 19; *abs. in Geogr. Jour.*, 45 (1915), No. 6, pp. 520-522).—A series of isomeric maps based upon rainfall records at 283 places, in most cases covering 35 years (1875 to 1909) and in no case less than 30 years, is given and their significance explained.

Seasonal distribution of rainfall in the British Isles (*Geogr. Jour.*, 45 (1915), No. 6, pp. 520-522).—The character of the seasonal variation of rainfall in the British Isles is described as bi-phase; "for whereas on the one hand there is a percentage excess in the wet, hilly, western parts of the country during the winter half of the year (October to March), with maximum in December and January, and a percentage excess in the dry, flat, eastern parts during the summer half (April to September), with maximum in July, on the other hand, throughout the country the isomeric values are lower during the spring half-year (January to June), with minimum in April, than during the autumn half (July to December), with maximum in October."

Atlas of agricultural meteorology.—I, Probability of droughts in European Russia, P. I. BROUNOV (*Atlasy po Selskokhoziâistvennoï Meteorologii. Vypusk I. Skhematicheskîû Karty Vîdroiâtnosti Nastuplenîû Zasukhlivnykh Dekad V Evropeiskoi Rossii. St. Petersburg: Met. Bur., 1913, pp. 7, pls. 21; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 6, pp. 663, 664).—The atlas consists of a brief explanatory text with 21 maps char-

acterizing European Russia according to drought periods during the growing season, April to October, inclusive.

A dry period is defined as one during which not more than 5 mm. of precipitation falls. The probability of such periods is computed in percentages denoting the ratio of the number of years with the given dry periods to the total number of years during which the observations were made, viz, sixteen.

Data from 390 meteorological stations were utilized in the preparation of the maps. The maps show, in general, that the rainfall gradually increases from April to June then diminishes to the end of the growing period.

SOILS—FERTILIZERS.

Soils of the cut and burned over areas of north Idaho, J. S. JONES and C. W. COLVER (*Idaho Sta. Bul. 81 (1915), pp. 20, figs. 5*).—This survey deals with the general characteristics, physical and chemical properties, crop adaptations, and fertility requirements of the soils of the cut and burned over areas of the panhandle of Idaho, which are included mainly in Bonner, Kootenai, and Latah counties and to a less extent in Clearwater and Shoshone counties.

The soils vary from river and lake bottoms to bench lands and level open prairies. The red sandy and silt loams are the predominating soil types. It is stated that the lowlands are rich in plant food, but that they need drainage. The bench and other highlands are rich in mineral plant food, but are usually acid in reaction and deficient in nitrogen and active organic matter. The open prairies, while not deficient in nitrogen, are usually acid and need treatment to make the native supply more readily available. "Unquestionably in the management of the cut and burned over lands the key to immediate and permanent success is a thorough understanding of practicable means of getting the element nitrogen into them and of making it available as plant food."

Data showing the amount of the various soil constituents are appended.

Bond County soils, C. G. HOPKINS ET AL. (*Illinois Sta. Soil Rpt. 8 (1913), pp. 58, pl. 1, figs. 9*).—This is the eighth of the series of the Illinois County soil reports and deals briefly with the physiography, topography, and formation of the soils and more fully with soil material and soil types, chemical composition of the soil, and field tests of the fertilizer requirements of some of the prevailing types.

Bond County lies in the lower Illinois glaciation. The soils of the county are divided into four classes, as follows: (1) Upland prairie soils, (2) upland timber soils, including those zones along stream courses over which forests once extended, (3) ridge soils, including those on morainal ridges most of which have been forested, and (4) bottom-land soils, including the flood plains along streams. The timber lands are divided into level, undulating, and hilly areas. The ridge soils are divided into pervious and almost impervious types.

The gray silt loam on tight clay of the upland prairie soil occupies nearly 33 per cent of the area of the county, while the brown-gray silt loam on tight clay, the yellow silt loam, and the yellow-gray silt loam are in their order next in extent, covering about 16.5, 16, and 13 per cent of the area respectively.

The total quantities of some of the necessary elements of fertility "are extremely limited when measured by the needs of large crop yields. . . . The variation among the different types of soil in Bond County with respect to their content of important plant-food elements is also very marked. Thus the richest prairie land (black silt loam on clay) contains about twice as much phosphorus and nitrogen as the common upland timber soils, and the bottom lands are still

richer in phosphorus. The most significant facts revealed . . . are the lack of limestone and the low phosphorus content of the common upland types, which cover nearly 90 per cent of the entire county."

The reclamation of an unproductive soil of the Kankakee marsh region. Soil acidity, nitrification, and the toxicity of soluble salts of aluminum, J. B. ABBOTT, S. D. CONNER, and H. R. SMALLEY (*Indiana Sta. Bul. 170, popular ed., pp. 2-8, figs. 3*).—This is a popular edition of Bulletin 170 (E. S. R., 30, p. 518).

Soils, J. C. BRÜNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, pp. 63, 68-85*).—Chemical and mechanical analyses of a large number of samples of soils from ten different districts of Queensland are reported. Many of the samples were tested for sulphur, and it was found "that the amount of total sulphur in a soil amounts on an average to about 0.08 per cent calculated as sulphur trioxid (SO_3), that the majority of samples do not vary greatly from this average figure, and that there seems to be ample sulphur in most of [the] soils to supply the requirements of crops for many years." It is stated that the grass soils analyzed as a rule showed high fertility.

Chemical studies of soils, S. TIJMSTRA (*Meded. Deli Proefstat. Medan, 8 (1914), No. 8, pp. 244-265*).—Studies of the chemical composition and physical properties of the soils of eight plats lying adjacent in two rows but subjected to different cultural treatment showed that the plats varied decidedly in both physical and chemical properties in spite of their apparent uniformity. These variations are not attributed altogether to the differences in cultivation, but are thought to be due largely to previously existing conditions in the soil. The plowing under of the ashes of burnt weeds on two plats which had not been previously cultivated was accompanied by a decrease in the content and solubility of phosphoric acid, a decrease in magnesium and iron, and an apparent increase in potash and chlorin.

It is thought that such variations should be given special consideration in judging the fertilizer and cultural requirements of a particular soil. The average of analyses of samples from different plats may not be a safe guide for such judgment.

Further studies along this line are in progress.

The sphere of adsorption phenomena in the soil, A. N. SOKOLOVSKIĪ (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 2, pp. 67-117, figs. 3; abs. in Zentbl. Agr. Chem., 44 (1915), No. 1, pp. 10-13*).—Studies of adsorption phenomena in the different layers of chernozem and podzol soils, with particular reference to their nature and the factors conditioning them, are reported.

The adsorptive power for bases was found, with one or two exceptions, to bear a close relation to hygroscopicity, and the activity of both factors decreased at higher temperatures. With reference to hygroscopicity, it is pointed out that water content, excluding the influence of salts, is a function of the so-called specific surface of the soil and increases with it. Absorption appeared to bear no relation to the amount of zeolitic constituents or the amount of silt present.

It was found that the amount of ammonia absorbed from ammonium chlorid varied with the soil layers according to the quantity of displaced bases. Adsorption with exchange of bases occurred to a rather low limit beyond which the exchange of bases ceased. The absorption of ammonia varied with the amount of dry residue obtained by displacing the soil solution with 96 per cent alcohol.

It is pointed out that the soil components which determine absorption are characterized by a great specific surface and a susceptibility to thermal and chemical influences, and the adsorption phenomena beyond a certain limit are

not accompanied by exchange reactions. The maximum specific surface and the maximum susceptibility to thermal influences are found in the upper soil sections in which the colloid formation processes are most intensive, thus showing a specific relation between absorption and the soil colloids.

On the assumption that the thickness of the water film on the soil particles remains constant, the following conclusions are drawn: The absorptive power of the absorbing medium decreases with a decrease in its effective surface. The absorption of calcium in the different layers of chernozem soil depends on the content of calcium which is already absorbed and is displaced by ammonium chlorid solution and not on its total calcium content. The podzol soil, on account of its extremely leached out condition and poverty in absorbed matter, shows a series of concordant results for phosphoric acid as well as for bases. Chernozem, on the other hand, on account of its complex formation, produces a regular series of results only for ammonia.

Removal of humus by oxidation with acid-free hydrogen peroxid showed that for chernozem, humus, even in the layers rich in it, did not appear to be an exclusive factor of absorption. In podzol soil the decrease in ammonia absorption due to this treatment amounted to 65 per cent of the original amount.

Influence of radio-activity of the air on exposed drop cultures of micro-organisms, A. TRILLAT and FOUASSIER (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 24, pp. 817-819).—It is shown that the growth of cultures of micro-organisms may be influenced to a marked extent by the radio-activity of the atmosphere, and that the latter may vary with the nature of the soil.

Studies of the microfauna of soils from rice localities, A. CAUDA and G. SANGIORGI (*Centbl. Bakt. [etc.]*, 2. Abt., 42 (1914), No. 15-16, pp. 393-398, figs. 6).—Studies of the microfauna of different soils and of the same soil under different cultural treatments are reported, and incidentally a comparison of culture media is made.

It was found that the composition of the culture medium exerted a definite influence on the development of protozoa. With the Omelianski and Giltay solutions the development was more marked than with the other solutions used. The development of protozoa began usually on the sixth or eighth day of incubation, proceeded until the fourteenth to eighteenth day, and then gradually subsided. The amœbæ were the prevailing forms and were present in all cases. In only one case were the flagellates more numerous than the amœbæ, and the flagellates and ciliates were sometimes entirely absent. The different soils showed marked variations in number and kind of protozoa. Soils widely separated but subjected to the same cultural treatment showed the same individual protozoan development.

It is thought that, aside from the physical, chemical, geological, and biological factors, certain other factors related to the nature of the vegetation exist in the soil which have a special influence on the vitality of the small-animal life of the soil.

Contribution to the knowledge of the physiology and distribution of denitrifying thiosulphate bacteria, A. GEHRING (*Centbl. Bakt. [etc.]*, 2. Abt., 42 (1914), No. 15-16, pp. 402-438).—The author briefly reviews work of others bearing on the subject, and reports studies of the anaerobic denitrifying sulphur bacteria found by Lieske (E. S. R., 28, p. 35) with reference to their physiology and distribution in soils.

These bacteria were found in different kinds of silt, in compost, cultivated soil, beech forest soil, and upland moor peat. The numbers were constant at different depths in peat and cultivated soil but varied greatly in the different soils examined, increasing with an increasing carbon content of the soil. Dif-

ferent races of these organisms showing great variations in virulence were distinguished in the different soils. It is stated that the races found in compost, beech forest soil, and peat may be combined into one great group in contrast to the race found in cultivated soil, and that the respective powers of transformation of these two groups stand in the ratio of 4:1.

Nitrate destruction increased in both soil and nutritive solution with an increasing thiosulphate content or increasing nitrate content. Nitrate could not be replaced as a source of oxygen by other compounds containing oxygen. It was possible to replace thiosulphate as a source of energy for the bacteria in question by other sulphur compounds but not by compounds not containing sulphur. Carbonate and bicarbonate were equally effective as sources of carbon.

The addition of thiosulphate to soils caused a strong denitrification, which was not, however, as strong as that caused by the addition of organic matter. The thiosulphate bacteria, by nitrate destruction, showed the same effect upon the physical condition of the soil as is attributed to the heterotrophic denitrifying bacteria by Koch and Pettit (E. S. R., 23, p. 123).

It is thought that the results obtained in these studies will serve to explain the results of a previous work of Thalau on the effect of sulphur compounds on plant growth (E. S. R., 29, p. 521).

The formation of leaf mold, F. V. COVILLE (*Ann. Rpt. Smithsn. Inst., 1913, pp. 333-343*).—This is a revision of an article which has already been noted from another source (E. S. R., 28, p. 814).

Soil tank experiments, S. E. COLLISON (*Florida Sta. Rpt. 1914, pp. LXXVII-LXXIX*).—Experiments with fertilizers for citrus trees were continued as in previous years (E. S. R., 31, p. 723), the data for composition of the drainage water obtained being tabulated.

It is stated that the losses of potash have continued to increase, being considerably larger than for the same period of the previous year. The opposite is noted with reference to nitrogen and the lime losses continue large. "The presence of comparatively large amounts of ammonia as such, in the water from tanks 1 and 2, indicates that a portion of the sulphate of ammonia applied leached through without being nitrified."

The origin, composition, and fertilizer value of the bat guanos of Cuba and the Isle of Pines. C. N. AGETON (*Modern Cuba, 3 (1915), No. 2, pp. 48-59*).—On the basis of analyses of samples from Cuba, Porto Rico, and Haiti it is stated that average bat guano contains from 3.5 to 7 per cent of phosphoric acid, 1.5 to 3 per cent of potash, and 8 to 11 per cent of nitrogen but varies widely in composition, depending upon the stage of decomposition, moisture content, leaching, admixture of foreign substances, and other conditions. "The fresh, friable bat excrement, which usually occurs as a thin covering over the floor of the cave, may easily be distinguished from the other classes of material. A light colored deposit may be expected to contain considerable quantities of calcium carbonate or gypsum, or both, the phosphoric acid content being quite variable but usually higher than in the fresh guano. The reddish or chocolate colored deposits or parts of deposits which have much the same appearance as a red or 'mulatto' soil, contain more phosphoric acid than the others, and usually they contain but very little, if any, nitrogen."

The use of the guano as a fertilizer is discussed.

The utilization of the nitrogen and organic matter in septic and Imhoff tank sludges, C. B. LIPMAN and P. S. BURGESS (*California Sta. Bul. 251 (1915), pp. 287-295*).—Analyses of a number of samples of the sludges are reported showing nitrogen varying from 1.23 to 2.66 per cent and phosphoric acid from 0.77 to 1.82 per cent. An attempt was made to judge of the availability of the nitrogen of the sludges by determining its rate of nitrification when mixed

with soils of different types. It was found that the different sludges behaved differently in any one soil, and that the different soils showed decidedly different capacities for rendering the nitrogen of the sludge available as measured by nitrates formed. The rate of nitrification, however, was generally higher than that of such high-grade materials as dried blood, tankage, fish guano, and cotton-seed meal.

The economic importance of utilizing sludge is discussed and suggestions as to the best methods of using it alone and with other fertilizers are given.

Peat, C. A. DAVIS (*U. S. Geol. Survey, Mineral Resources of the United States Calendar Year 1913, pt. 2, pp. 383-392*).—This is a review for 1913 of data relating to the production and use of peat in the United States and abroad.

[Utilization of prickly pear as a fertilizer], T. H. JOHNSTON and H. TRYON (*Rpt. Prickly-Pear Travel. Com., Queensland, 1912-1914, pp. 25, 26*).—The use of prickly pear as a fertilizer as practiced in Madras, Mysore, and the Bombay Presidency, of India, is briefly described.

The action of liquid manure as a nitrogenous fertilizer, B. SCHULZE (*Ztschr. Landw. Kammer Schlesien, 18 (1914), No. 44, p. 1630*).—Comparative tests on potatoes, beets, and oats of equal amounts of nitrogen in the form of nitrate and of liquid manure are briefly reported, indicating that the utilization of the nitrogen of the nitrate was about 60 per cent, while that of the liquid manure was about 41 per cent.

The manufacture of nitrates from the atmosphere, E. K. SCOTT (*Ann. Rpt. Smithsn. Inst., 1913, pp. 359-384, pls. 3, figs. 7*).—This is a reprint of an article which has already been noted from another source (*E. S. R., 27, p. 420*).

The action of certain new nitrogenous fertilizers on sandy and upland moor soils, B. TACKE (*Mitt. Ver. Förd. Moorkultur Deut. Reiche, 32 (1914), No. 23, pp. 411-424*).—Comparative field tests on oats, rye, and potatoes grown on sandy and moor soils of different kinds showed that ammonium nitrate, calcium nitrate, urea, and superphosphate prepared with synthetic nitric acid were, as a rule, as effective as sodium nitrate and ammonium sulphate and may be substituted for them if the price permits this to be profitably done. The Schloesing nitrate was apparently less effective on the well-limed moor soils than the other fertilizing materials tested.

[Some chemical and agricultural effects of fertilizer mixtures containing calcium cyanamid], C. J. KING (*Com. Fert., 10 (1915), No. 1, pp. 14-16*).—Continuing previous work by Brackett (*E. S. R., 30, p. 26*), the author studied changes in the soluble phosphoric acid and nitrogen content in mixtures of acid phosphate, calcium cyanamid, and muriate of potash, and also the effect of such mixtures on the growth of cotton.

The results confirm those of previous experiments in showing that there was a considerable reversion of phosphoric acid in the mixtures after standing a few months. After six months of storage the amount of insoluble phosphoric acid had increased from 0.4 to 2.01 per cent. There was no appreciable loss of nitrogen in that time. The field tests of the mixtures on cotton indicated a depreciation in their fertilizing effect within one month after the mixtures were made.

The kelp industry (*Rpt. Bd. Agr. Scot., Home Indus. Highlands and Islands, 1913, pp. 118-131; abs. in Jour. Franklin Inst., 179 (1915), No. 2, p. 260*).—Attention is called to the marked increase in the production of kelp in the British Isles since 1905 and a brief account is given of methods of utilization employed, especially in Scotland, and of the products which may be obtained.

It is stated that Scotch seaweed is much richer in iodine than Pacific coast kelps or Japanese seaweeds and is, therefore, especially valuable as a source of supply of this substance, particularly in view of the present shortage of the

supply derived from Chilean nitrate. A brief account is also given of progress in the utilization of seaweed in the United States, particularly of the Pacific coast kelps.

The new potash deposits in Spain (*Abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 11, pp. 1423, 1424; 6 (1915), No. 1, pp. 53-55*).—Various reports and articles on this subject are reviewed showing (1) the Government's plan of regulating the exploitation of the deposits, (2) the acquisition of a concession by an American company, (3) the views of Schmidt and others of the German Geological Society on the nature and value of the Spanish deposits, and (4) the prospect of the Spanish potash salts appearing in commerce.

It is stated that "the deposits of potash salts are found in the Tertiary strata of the Elbro basin, i. e., in the same region as the large mass of rock salt at Cardona, known since antiquity. The discovery was made by a small contractor who came across layers of carnallite and sylvin whilst boring in the neighborhood of Cardona. Prospecting made up to the present shows that there is a deposit 260 ft. in thickness, containing 70 ft. of beds of carnallite with 20 per cent potassium chlorid, and 33 ft. of sylvin with 95 per cent potassium chlorid. Later explorations will establish the extent of these deposits. In origin they are analogous to those of Alsace, i. e., they are not primary formations resulting from the evaporation of sea water but secondary formations derived from more ancient saline deposits, probably from Triassic saline deposits of the Pyrenees and the coast ranges of Catalonia." The opinion of a French technical expert is cited to the effect that these deposits compare in richness and quality with the best German deposits and have the advantage of being more easily accessible.

Potash deposits in Catalonia (*Zentbl. Kunstdünger Indus., 19 (1914), No. 16, pp. 338, 339; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 11, pp. 1423, 1424*).—This is a brief discussion, by K. Schmidt and others, of the German Geological Society, of these deposits as noted above.

Lime in agriculture, F. T. SHUTT (*Canada Expt. Farms Bul. 80 (1914), pp. 16*).—This is a popular discussion of the nature of lime and limestone, agricultural functions of lime and its compounds, comparative values and methods of application of lime compounds, and the use and misuse of lime.

Ground limestone for acid soils, J. F. BARKER and R. C. COLLISON (*New York State Sta. Bul. 400 (1915), pp. 145-163, pl. 1*).—The first section of this bulletin discusses briefly the chemical composition of limestones, with a table showing the carbonate content and calcium carbonate equivalent of the ground limestones produced in the various quarries of New York and of the principal ones brought in from outside. Following sections discuss the practical use of ground limestone on acid soils and give compiled data showing the returns from the use of limestone on various crops and soils.

It is stated that three-fourths or more of the farm lands of New York would be greatly benefited by a liberal application of lime in some form. Limestone is considered likely to produce better results than burned lime and is safer and more convenient to apply. The relation of magnesium in limestone to its practical use is pointed out.

Theoretical considerations and experiments in the use of ground limestone are reviewed to show that fineness greater than is necessary to allow all the material to pass through a 10-mesh sieve is not required for satisfactory use.

Gypsum, R. W. STONE (*U. S. Geol. Survey, Mineral Resources of the United States Calendar Year 1913, pt. 2, pp. 355-372*).—This is a review for 1913 of data relating to the sources, production, and use of gypsum.

Analyses and valuations of commercial fertilizers, C. S. CATHCART ET AL. (*New Jersey Stas. Bul.* 274 (1914), pp. 3-63).—Analyses and valuations of 935 samples of fertilizers and fertilizing materials offered for sale in New Jersey during 1914 are reported. The average composition, valuation, and selling price of the 60S mixed fertilizers examined were as follows: Total nitrogen 2.66 per cent, total phosphoric acid 9.24, available phosphoric acid 7.75, potash 6.91, station's valuation \$22.40, and selling price \$29.51. Of the 60S mixed fertilizers 420 were found to be as guaranteed. The reported tonnage for the year ended October 31 was 155,414 tons.

Fertilizer registrations, C. S. CATHCART (*New Jersey Stas. Bul.* 275 (1915), pp. 3-34).—A list of brands, with guaranteed composition, of mixed fertilizers and fertilizer materials offered for sale in New Jersey during the fiscal year ended October 31, 1915, is given.

AGRICULTURAL BOTANY.

Applied and economic botany, H. KRAEMER (*Philadelphia: Author, 1914*, pp. VI+806, pls. 2, figs. 420).—This book is designed to meet the needs of students in technical schools and in agricultural, pharmaceutical, and medical colleges, also to serve as a book of reference for chemists, food analysts, and students in the morphological and physiological study of plants. The facts and illustrations presented are intended to give the latest information regarding morphology, origin, and distribution, also chemical nature, of the plants studied. On account of the contamination of the materials on the market, especially with lower plant forms, a more or less succinct treatment of the principal groups of lower and higher forms is given. The several chapters deal with the principal groups of plants, cell contents and forms of cells, outer and inner morphology of the higher plants, botanical nomenclature, classification of angiosperms yielding economic products, cultivation of medicinal plants, and microscopic technique and reagents.

The vegetation of Nantucket, J. W. HARSHBERGER (*Reprint from Bul. Geogr. Soc. Philadelphia, 12 (1914), No. 2, pp. 70-79, pls. 5, fig. 1*).—Giving a brief description of the vegetation on the island of Nantucket, the author states that the two main factors in producing the present almost treeless condition of the island are the evaporating action of the wind and the nature of the soil.

The character of the tubers of *Batatas edulis*, Z. KAMERLING (*Ber. Deut. Bot. Gesell., 32 (1914), No. 5, pp. 352-360, figs. 8*).—From work as carried out with *B. edulis* to determine whether its tubers are to be regarded as roots or stems, the author concludes that the significance of these bodies lies in their relation to the vegetative propagation of the plant.

The structure of clover blooms, V. FOMINYKH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 5, pp. 395-400, figs. 4*).—The author describes the nectary of *Trifolium pratense*, which, it is claimed, has not been adequately done heretofore.

Studies of *Camptosorus rhizophyllus*, F. L. PICKETT (*Proc. Ind. Acad. Sci., 1913, pp. 129, 130*).—Studies on this plant show it to possess two important adaptive factors, namely, an unusual power of promiscuous growth in the prothallial cells and ability to resist extreme desiccation.

The sexuality of rust fungi, F. RAWITSCHER (*Ber. Deut. Bot. Gesell., 32 (1914), No. 5, pp. 310-314, figs. 4*).—This is a brief report of some preliminary observations, noting more particularly the copulation of sporidia in *Tilletia tritici* and the subsequent behavior of the resulting binucleate hyphae.

Recent aspects of mutation, R. R. GATES (*Nature [London], 94 (1914), No. 2350, pp. 296-299*).—This is mainly a review of recent publications regarding

cytological and morphological characters and inheritance, particularly as noted in species of *Oenothera* and their mutants.

Growth and variation in maize, R. PEARL and F. M. SURFACE (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 4, pp. 222-226, fig. 1; *abs. in Maine Sta. Bul.* 234 (1914), pp. 290, 291).—The investigation reported in this paper is an attempt to analyze the normal variation of maize from the standpoint of its development. The authors tried, by studying the growth of the individual, to analyze the adult variation curve into its component elements as a beginning at an understanding of the developmental physiology of the genes concerned in the production of the characters studied. Measurements were made twice a week of the height of each individual of three series of plants of a variety of sweet corn.

The evidence indicates that the observed differences in the manner of growth of individual plants and groups of plants can not be explained as the effect of external environmental factors, but are rather to be looked upon as the effect of internal factors. The distribution of the average relative size of individual plants is such as to suggest the random distribution of these factors among the plants. The simplest method of explaining these facts is believed to be to regard the differences in the manner of growth as due to independent Mendelian factors which are distributed at random in any population of open fertilized maize plants. By assuming the presence of two independent growth factors and weighing each with the proper value, the authors consider it possible to obtain a theoretical distribution which agrees very closely with the observed distribution. The interpretation of the growth of these plants by Mendelian factors is said to be strongly supported by the distribution of the standard deviation of the plants with different relative sizes.

The causes of growth in plants, III, G. A. BOROWIKOW (*Kolloid Ztschr.*, 15 (1914), No. 1, pp. 27-30).—Having noted (E. S. R., 29, p. 429) that the hydration of plasma colloids appears to be one of the most important factors in plant growth, at least in case of *Helianthus annuus*, and that an exception to this rule may be observed to result from the presence of the respiratory product carbon dioxide in the nutritive solution, the author has carried out further investigations which are here briefly discussed.

It was found that concentration of the cell sap and rapidity of growth bear an inverse rather than a direct relation to each other, slight alterations in the one often corresponding to great changes in the other, the possible bearings of this fact being discussed. It is thought that the periods of growth through which each cell passes may be related to stages in the rapidity of hydration of the cell colloids.

Further studies on the colloidal and physical chemistry of the cell, W. RÜHLAND (*Jahrb. Wiss. Bot. [Pringsheim]*, 54 (1914), No. 3, pp. 391-447).—The author has continued work previously noted (E. S. R., 30, p. 28), detailing results and inferences from a study of carbohydrates, alkaloids, glucosids, and acids, also those from a study of the physicochemical properties of the cell in general and of the cell as an ultra-filter in particular. It is stated that the function of an ultra-filter is exercised by the plasma membrane and not by the cell wall.

The influence of ultraviolet rays on chlorophyll-containing cells, J. STOKLASA (*Ztschr. Pflanzenkrank.*, 24 (1914), No. 4, pp. 193-204).—In the course of numerous experiments here reported, dealing with a number of plants, it appears that the briefer exposures (two hours) to ultraviolet rays (of wave lengths 300 to 500 $\mu\mu$) generally cause rapid development of chlorophyll in etiolated leaves, while longer exposures either produce results not much greater than

those from ordinary sunlight, or else tend toward destruction of the vitality of the superficial leaf cells, resulting in discoloration and death of the foliage without, however, injuring the rest of the plant or decreasing its power of foliage reproduction. These results largely confirm those reported by Maquenne and Demoussy (E. S. R., 22, p. 436). Plasmolytic tests show that in some cases at least the upper surface of the stomatal guard cells is most readily affected. The discoloration of the leaves is explained by the chemical changes in the dead protoplasm. Flower petals are more quickly altered than are leaves by the ultraviolet rays, both flowers and leaves of indoor plants being more readily affected than are those of outdoor plants, and the species being more significant in this connection than the flower color.

It is regarded as established that ultraviolet rays exert a great influence on the development of chlorophyll-forming organs as well as upon the activity of these organs, but that prolonged action of such rays disturbs profoundly the life processes in the leaf cells.

The relation of chlorophyll formation to light wave length, A. SCHMIDT (*Beitr. Biol. Pflanz.*, 12 (1914), No. 2, pp. 269-294, pls. 2).—Noting briefly studies of other authors as cited on the relations of light, chlorophyll, and assimilation, the author gives an account of his own investigations, employing *Zea mays*, in regard to the influence of different wave lengths of light on the synthesis of chlorophyll.

The results are said to present analogies to those noted by Kniep and Minder (E. S. R., 22, p. 229) and by Lubimenko (E. S. R., 25, p. 431) regarding the assimilation of carbon dioxide, inasmuch as for chlorophyll formation, as well as for assimilation, there are two maxima, the blue rays possessing a greater significance than was formerly ascribed to them in this regard.

A bibliography is appended.

A simple apparatus for the study of phototropic responses in seedlings, G. N. HOFFER (*Proc. Ind. Acad. Sci.*, 1913, pp. 93-96, figs. 4).—This apparatus, made up chiefly of the microscope with a micrometer eyepiece attached to the side of its carrying case used as a dark chamber, is employed to observe minute responses of seedlings and fungi to filtered solar rays.

Irritability as related to plasmatic conditions, A. HEILBRONN (*Jahrb. Wiss. Bot. [Pringsheim]*, 54 (1914), No. 3, pp. 357-390, fig. 1).—In a study of *Vicia faba* and *Arcua sativa* the author found the viscosity of living substance to have a minimum of 9 times and an average of 24 times that of water. It is concluded also that cell plasma opposes not only chemical but physical properties to influences tending to limit motion therein.

A bibliography is given.

Transpiration of *Silphium laciniatum*, L. A. GIDDINGS (*Plant World*, 17 (1914), No. 11, pp. 309-328, figs. 10).—This is a detailed account of experiments already reported (E. S. R., 30, p. 726).

The physiology of germination, G. MÜLLER (*Jahrb. Wiss. Bot. [Pringsheim]*, 54 (1914), No. 4, pp. 529-644, figs. 35).—The author states, among other findings, that the causes of pressure noted as tending to burst the seed coats are imbibed water and growth of endosperm, cotyledons, or rootlets. The structural arrangements favoring escape of the embryo are described as belonging to five different types. Pressures found to develop during changes in the cotyledons and endosperm are given. The resistance of dehiscence lines in seed coats is said to be lessened by the presence of water.

A bibliography is appended.

The germination of seeds of *Arisæma*, F. L. PICKETT (*Proc. Ind. Acad. Sci.*, 1913, pp. 125-128, figs. 6).—Seeds of *A. triphyllum* gave a high percentage of germination, and it is noted that some germinate blindly, that is, the embryo

grows, a corm and roots are produced, and food is transferred from seed to corm without the formation of leaves or other photosynthetic organ. At the end of the growing season the connection with the seed is broken off, leaving the new plant independent. Some corms are from three to six times as large as others under apparently the same conditions.

A similar set of experiments with *A. dracontium* showed that in this species the formation of leaves is a somewhat rare exception. Other evidence of incomplete response to seasonal changes was observed, and the suggestion is made of a definite periodicity requiring more than the usual rest season for this plant.

The longevity of submerged seeds, G. H. SHULL (*Plant World*, 17 (1914), No. 11, pp. 329-337, figs. 2).—The appearance of more than 140 species of plants on the dried bed of an old mill pond that had been drained suggested additional tests on the viability of seeds of some of these species. It was found that under laboratory conditions a number of seeds germinated after a submergence of more than four years, and some seeds are said to have been viable after seven years of continual submergence.

The assimilation of atmospheric nitrogen, and the reaction of albuminoid material contained in specialized hairs of plants cultivated in oxygen without nitrogen, F. KÖVESSI (*Rev. Gén. Bot.*, 25 bis (1914), pp. 405-415).—The author cites recent studies claimed to have been very carefully carried out and to confirm his conclusions previously announced (*E. S. R.*, 32, p. 327).

Biochemical influence of manganese, A. PUGLIESE (*Atti R. Ist. Incoragg. Napoli*, 6. ser., 65 (1913), pp. 289-315).—Detailing investigations regarding the antagonism between iron and manganese in nutritive solutions for wheat, etc., the author agrees with Masoni (*E. S. R.*, 26, p. 226) in claiming that such antagonism exists, and he states that the optimum ratio for these two materials seems to be in the neighborhood of 1:2.5.

The action of antimoniocal salts on the respiration of plants, W. PALLADIN and G. COHNSTAMM (*Rev. Gén. Bot.*, 25 bis (1914), pp. 539-555).—The authors found that the respiration of etiolated shoot tips of vetch is stimulated by 1 per cent of antimony tartrate, as by other poisons (*E. S. R.*, 23, p. 629), presumably as a defensive reaction against the poison, while the respiration of germinating peas is decreased by that solution. The difference is ascribed to the deficiency of respiratory chromogens in peas, and the consequent lessened absorption of oxygen by them. The normal coefficient of respiration is but little affected in seeds of peas and shoots of vetch by this poison, but in young rootlets of sprouting peas, which normally show the coefficient $\text{CO}_2:\text{O}_2=1:2$, the coefficient becomes $\text{CO}_2:\text{O}_2=1$, corresponding to a decrease in growth rate. The action of this salt decreases the respiration of dead cells. Seeds poisoned with antimony after freezing give off a decreased amount of carbon dioxide.

Volatile acids in fermentation products of some anaerobic bacteria, G. SELIBER (*Rev. Gén. Bot.*, 25 bis (1914), pp. 589-598).—Giving details and results of work according to the method of Duclaux, as formerly noted (*E. S. R.*, 24, p. 120), and using cultures of *Bacillus butyricus*, *B. perfringens*, and *B. putrificus*, the author states that the first of these produces butyric and acetic acid and the second produces acetic and formic acid (propionic acid also being noted in some of the cultures). For *B. putrificus* it is difficult to ascertain the exact nature of the volatile acids produced. It is said to have been shown that under constant conditions of culture the same acids are produced constantly by a given species of the organism.

Fatal temperatures for some diastases of animal or vegetable origin, E. C. TEODORESCO (*Rev. Gén. Bot.*, 25 bis (1914), pp. 599-627).—Giving further details (*E. S. R.*, 28, p. 803) of tests made with diastases heated to varying degrees,

the author states that when dried these support for a short period (one-half hour) temperatures above 100° C., and in some cases much higher. Some suggestions as to the nature of these bodies are also offered.

Excretion of toxic substances by roots, D. PRIANICHNIKOV (*Rev. Gén. Bot.*, 25 bis (1914), pp. 563-582, figs. 11).—This is mainly a discussion of the work done by Periturin (E. S. R., 30, p. 426), the results of which agree in part with those of American investigators named.

Alterations in the forms of antagonism curves, W. J. V. OSTERHOUT (*Jahrb. Wiss. Bot. [Pringsheim]*, 54 (1914), No. 4, pp. 645-650, fig. 1).—The author, reporting an extension of work previously noted (E. S. R., 26, p. 823; 29, p. 627), shows by tables and curves how the antagonism between given percentages of sodium chlorid and calcium chlorid may vary from time to time in the course of a given experiment. This is held to be due to progressive alterations in the permeability toward each salt of the living material employed, which in this case consisted of portions of *Laminaria saccharina*. It is thought that these two salts act in different ways to influence permeability.

The influence of X-rays on vegetation, E. MÈGE and H. COUPÉ (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 4, pp. 338-340, pl. 1).—Reporting experiments with seedlings of *Raphanus sativus* and *Lepidium sativum* subjected for about 38 days after planting to strong and frequent applications of X-rays, the author claims that this preliminary study shows that these rays exert a favorable influence upon the foliage, but more upon the underground portions of these plants. The effect increases with the frequency and strength of the application (even within limits dangerous to animal tissues), and the rays affect the morphology and structure of these plants when grown under their influence.

FIELD CROPS.

Plant breeding, G. F. FREEMAN and J. C. T. UPHOF (*Arizona Sta. Rpt. 1914*, pp. 343-348).—In variety tests reported with alfalfa it is noted that Peruvian alfalfa has demonstrated its excellence for the region. In physiological studies as to the nature of drought resistance, the results suggest a distinct relation between the transpiration rate and the number of stomata on a given leaf surface.

It is noted that the sweet corn breeding experiments have resulted in producing a variety that is hardy and drought and heat resistant from a few grains originally found among the native corn grown by the Papago Indians.

Cultural work with tepary beans and variety tests with wheats are also reported.

[Field experiments], A. M. McOMIE (*Arizona Sta. Rpt. 1914*, pp. 330-333, 334-337).—Cultural tests being carried on at Phoenix and at the dry farms at Sulphur Spring Valley, Prescott, and Snowflake with wheat, oats, rye, Indian beans, millet, Sudan grass, corn, sugar beets, sugar cane, sorghums, potatoes, legumes for cover and forage crops, millets, flax, and teosinte, and breeding work with alfalfa are briefly reported.

[Field-crop trials], J. M. SCOTT (*Florida Sta. Rpt. 1914*, pp. XXII-XXIX).—This gives results of cultural trials of Sudan grass, teff, Wakulla bean, Yokohama bean, Alachua bean, Florida velvet bean, soy beans, cowpeas, sweet potatoes, Chinese velvet bean, and kudzu bean.

Sudan grass yields ranged from 1,245 to 4,960 lbs. of cured hay per acre in 1913. "The sowings made in March produced only one cutting during the year, while the later [April and May] sowings gave two cuttings."

In fertilizer trials with Japanese cane results showed that "potash gave a decided increase in yield; ammonia gave an increased yield; sulphate of ammonia produced a little better yield on the average than did dried blood; acid phosphate apparently gave no increase in yield; sulphate of potash produced a little better yield than did muriate of potash."

[Field-crops experiments], J. B. GARRETT and F. C. QUEREAU (*Louisiana Stas. Rpt. 1914, pp. 22-26, 28-30*).—At the North Louisiana Station it is noted that in rotation experiments little difference was produced by the use of raw rock phosphate at the rate of 2,700 lbs. per acre every third year and acid phosphate applied at the rate of 300 lbs. per acre. "On the raw rock phosphate plat 1,207 lbs. per acre of seed cotton were produced and 27.9 bu. of corn, and on the acid phosphate plat 1,228 lbs. of seed cotton and 27.7 bu. of corn."

Sudan grass yielded 5.43 tons of hay per acre in two cuttings on the red type of soil. Of cowpeas, "the New Era, Groit, and Iron varieties produced 32.3, 26.35, and 20.96 bu. per acre, respectively. Two pickings were secured from each of these varieties. The Whippoorwill, which is the standard variety in this section, only produced 10.2 bu. per acre. Ordinarily, 10 or 12 bu. of peas per acre is a good crop here."

Yields are also reported for sorghum, feterita, Kafir corn, milo maize, ribbon cane, and Japanese cane.

In regard to fertilizer experiments with rice at Crowley, it is stated that "it is likely that 16 per cent acid phosphate is our best and cheapest source of phosphorus. The results of the past five years indicate that a 200-lb. per acre application will give the best and the cheapest returns. Kainit when applied to old rice land seems to make considerable increase in yield the first year, but in succeeding years the yield is but little better than the yield on the check plats, where no fertilizer has been used. Applications of phosphate and kainit in equal parts do not make increase in yield over the plats where phosphate is used alone.

"It is indicated by these experiments that cotton-seed meal may profitably be applied to Honduras rice, but that the returns are not so great with Blue Rose or Shiriki, this especially marked in the case of the former. It is not believed that it is profitable to use cotton-seed meal or other nitrogenous fertilizer on Blue Rose rice. Water crab grass is observed to grow on all plats fertilized with acid phosphate. This was especially noticeable last year (1914). On plats fertilized with kainit and where there was no fertilizer there was little if any crab grass. On the phosphate plats there was a heavy stand of grass which could not be checked with water and which caused considerable decrease in the yields of rice in these plats.

"As these results clearly indicate that phosphate promotes the growth of grass as well as the growth and yield of rice, it would seem that the fertilizer should be placed as close to the rice plant as possible. In other words, the fertilizer should be placed in the row with the seed, but not in contact with it. In this way the rice would get the benefit of the fertilizer first and would have a better chance to get away from the grass. It is good practice to drain the land fifteen days from the time of the first flooding. This will check the activity of the 'root maggot,' and it is believed that the drying out of the land at this time is a good thing for the rice. Where it is possible to do so, the land should be drained twice during the irrigating season."

Rotation trials are also summarized, the results indicating that highland crops will, if continued long enough, eliminate red rice. It is believed that less than a six-year rotation will not be profitable.

Field experiments, C. D. WOODS (*Maine Sta. Bul. 236 (1915), pp. 41-51, 63, 64*).—Yields in 1914 of variety tests of commercial varieties of oats are given

ranging from 76 to 105 bu. per acre, and of new varieties originated at Highmoor Farm ranging from 81.5 to 120 bu. per acre.

In testing rates of seeding for oats, 16 pk. per acre gave better yields than 8, 10, 12, 14, or 20 pk. per acre in 1914 in Aroostook County. An experiment comparing sulphate of ammonia and nitrate of soda as sources of nitrogen for potato fertilizers is noted as in progress, the first year's trial being favorable to the latter. Experiments comparing different methods of applying fertilizers to potatoes are also noted as in progress, with no marked differences thus far.

It is noted that spraying potato fields with iron sulphate to kill wild mustard, in 1914, did not give as satisfactory results as previously noted (E. S. R., 31, p. 133).

In a rotation experiment to test the effect of sweet corn on a succeeding grass crop no injurious effect has been shown thus far.

Experiments with farm crops in southwest Missouri, C. B. HUTCHISON and T. R. DOUGLASS (*Missouri Sta. Bul.* 123 (1915), pp. 163-185, figs. 3).—This bulletin gives results of several years' work with field crops on a red limestone soil classed as Crawford silt loam. Variety tests included corn, oats, barley, and wheat. A 4-year rotation experiment included corn, oats, wheat, and cowpeas and soy beans.

In an average of three years, drilling oats gave an increase of 2.8 bu. per acre over broadcasting. The greatest increase occurred in the most favorable oat season. Winter oats seemed to be an unreliable crop for this section. Drilling cowpeas at the rate of 4 pk. per acre gave 4,475 lbs. of cured hay, a larger amount than broadcasting or planting with a corn planter.

In alfalfa experiments the use of lime 4,500 lbs., manure 27,000 lbs., and bone meal 300 lbs. per acre gave better yields than limestone alone or than limestone and manure. The yields of hay are given as 11,698, 4,085, and 7,455 lbs. respectively, with 778 lbs. per acre with no treatment.

Under miscellaneous cultural experiments were included rape, crimson clover, and hairy vetch.

Recommendations for the management of crops in this region and possible cropping systems are given.

Soil fertility problems, E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 8, pp. 2-6, fig. 1).—This reports results of a one-year soil fertility test on "rather sandy muck soil." From the yields of mangels, corn, potatoes, and thousand-headed kale in field plats the following conclusions have been drawn:

"The yields of all four crops clearly show that potash is the limiting factor on this muck soil. Potash alone or in combination has produced about the same results. Lime has increased the yield of three of the four crops, probably because it helps to liberate potash. Nitrogen and phosphorus alone have not increased the yield. Finally, manure has increased the yield more than any other single fertilizer or combination of fertilizers used."

Pot tests with oats on this soil, a new "shot clay," and fine sandy loam indicated the great value of manure.

[Cultural and fertilizer experiments], E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 10, pp. 7-10).—This reports variety tests, for the seasons 1913-14, of oats, barley, wheat, peas, vetch, navy beans, soy beans, cowpeas, corn, kale, marrow cabbage, mangels, sugar beets, swedes, turnips, red clover, alfalfa, millet, and buckwheat; cultural tests with tangier pea, clovers, espersette, serradella, Italian rye grass, meadow fescue, orchard grass, Kentucky blue grass, and other grasses, rape, penicillaria, teosinte, and sorghums. Pot experiments in fertilizing upland "shot clay," valley "fine sandy loam," and muck soils are noted as in progress.

The growing of succulent feeds for fall and winter use.—I, **Root crops**, E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul., 1 (1913), No. 4, pp. 9-13, figs. 12*).—This reports yields in variety tests of mangels, carrots, ruta-bagas, and turnips grown as stock feed, with brief cultural notes.

The growing of succulent feeds for fall and winter use.—II [Winter forage and miscellaneous crops], E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul., 1 (1914), No. 5, pp. 8-10, figs. 2*).—Cultural methods are given for kale, marrow cabbage, rape, cabbage, and potatoes as grown for succulent feed for stock, and yields are reported for the three first-named crops.

Summary of results [with] cereals, 1914, C. E. SAUNDERS ET AL. (*Canada Expt. Farms Bul. 81 (1914), pp. 31*).—This gives results of variety tests and describes recommended varieties of wheat, oats, emmer, spelt, barley, rye, field peas, beans, flax, and buckwheat for the maritime Provinces, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

Report of assistant botanist, J. BELLING (*Florida Sta. Rpt. 1914, pp. LXXXI-CVI, figs. 5*).—This reports a continuation of work previously noted (E. S. R., 31, p. 734) in regard to the inheritance of pubescence of pods and plants in crosses between the Florida velvet bean and the Lyon bean to the fifth generation, and between Florida and Yokohama, and Florida and China, to the third generation.

The inheritance and segregation of characters, stinging, downy, velvet, and black are discussed and noted as following closely the Mendelian calculations. In a study of the inheritance of partial sterility in the first generation hybrids of these bean crosses, the author believes that the discovery of empty pollen grains and of aborted embryo sacs shows a segregation of genetic differences, for in the partially sterile progeny certain corresponding paternal and maternal chromosomes have apparently not been correspondingly paired. See also a previous note (E. S. R., 32, p. 725).

Corn crosses are also briefly noted.

Corn, J. R. RICKS and C. T. AMES (*Mississippi Sta. Bul. 170 (1915), pp. 3-15*).—This bulletin gives results of experiments with corn, consisting of variety tests, cost of growing, dates of planting, fertilizers, cultural methods, subsoiling, spacing, suckering, and the production of silage corn.

In tests of 32 varieties from 1911 to 1914, inclusive, yields ranged from 21.9 to 59.4 bu. per acre at Agricultural College. The cost of production of corn per acre was \$12.50 and per bushed 26.3 cts. Commercial fertilizers do not seem to have been successful. "A crop of cowpeas gives us better returns than commercial fertilizers." Subsoiling was deemed to be of no value in increasing the yield of corn. Early (March) planting showed better results than late (June) planting, and flat cultivation better yields than ridge cultivation. Cultivation continued until tasseling of the corn began showed better yields than early cultivation only. Corn spaced 1 ft. in the row gave better yields than when spaced 2, 3, or 4 ft. for early planting, but in late planting 2 and 3 ft. spacing gave the best results. Breaking the sucker when the corn was 4 or 6 ft. high was found to be injurious. Ten tons of barnyard manure per acre always gave an increase in the yield.

Silage corn yielded from 6.3 to 10.9 tons per acre. "For 3 years the average cost per ton of silage at this station has been \$1.92. This includes everything from the rent on the land up until the silage is in the silo."

Tests of 19 varieties of corn at the Holly Springs substation show yields ranging from 30.5 to 92.2 bu. per acre in 1908, 1912, 1913, and 1914.

Methods of treatment for weevils in stored grain by the use of carbon bisulphid, by R. W. Harned, are appended.

Corn experiments, C. G. WILLIAMS and F. A. WELTON (*Ohio Sta. Bul.* 282 (1915), pp. 71-109, figs. 8).—This bulletin gives results of experiments with corn that have been running for various lengths of time, in some cases covering over 20 years. Data are presented in 36 tables.

“Comparing a 5-year rotation system with the continuous growing of corn, the former has given an increase of 13 to 14.79 bu. per acre, in spite of the heavier use of manure and fertilizers under continuous culture. Comparing a 5-year with a 3-year rotation, the latter has given an increase of 6 to 8.39 bu. per acre. Comparing a 3-year rotation with continuous cropping, no fertilizers used in either case, the yield of corn from the former is 127 per cent greater than the latter.

“The use of phosphorus, alone, in the form of acid phosphate, has increased the yield of corn 8.28 bu. per acre. The use of manure alone has increased the yield 31.27 bu. per acre as an 8-year average. The use of acid phosphate and manure has increased the yield 40.58 bu., thus leaving 9.31 bu. to be credited to the acid phosphate.

“On such acid soils as are found on the station farm at Wooster, 1 ton of burned lime or 2 tons of ground limestone, applied once in 5 years, has increased the yield of corn on an average 7.35 bu. per acre on the fertilized plats, and 8.25 bu. per acre on the unfertilized plats. Taking into consideration all the crops of the rotation the application of lime has been worth, on the average, \$14.21 per acre per rotation. The cost of the lime has been \$5.

“Comparing very deep plowing with ordinary plowing and with subsoiling, the 5-year average gain for subsoiling has been 2.32 bu. per acre, and for the deep plowing 0.43 bu. per acre.

“Plantings of corn made at Wooster from May 4 to 10 have given larger yields of shelled corn per acre than the plantings of other dates, though the moisture content and the shrinkage have been lower from the plantings made from April 24 to 29. Of the plantings of the latter dates, 78.62 lbs. of ears as weighed in November have been required to equal a bushel of shelled corn in April, while of the plantings of June 2 to 6, 91.95 lbs. of ears have been required. The variety of corn and all the conditions of growth except date of planting have been the same.

“Where the distance between rows and the number of plants per acre have been the same, one plant every 12 in. has outyielded 3 plants every 36 in. by 4.55 bu. per acre. With hills 42 in. apart each way, the maximum yield of shelled corn, as a 10-year average, has been secured from 4 plants per hill, or 14,220 plants per acre.

“Nine years' tests of deep (4 in.) as compared with shallow cultivation (1½ in.) show an average gain of 4 bu. per acre in favor of shallow cultivation. Two years' tests of late cultivations of corn with a one-horse cultivator, after two-horse implements had to be discarded, show an average gain of 3.44 bu. per acre for late cultivation.

“A 10-year average variation of 6.25 bu. per acre has been found in varieties of corn well acclimated to the locality where tested. A variation in yield of 24.29 bu. per acre has been found in varieties grown and sold for seed within the State.

“A comparison of ears varying 2.44 in. in length, on the average, shows a difference in yield of only 1.39 bu. per acre, as a 10-year average—a difference no greater than might have been expected had the seed used been identical. While there is a slight decrease in length of ear in the short-eared strain, it has not materially affected the yield. As a 9-year average, tapering ears have excelled cylindrical ears in yield by 1.65 bu. per acre.

"Eight years' continuous selection for bare, as compared with filled tips, shows an average difference of 0.34 bu. per acre in favor of filled tips. Comparing rough with smooth dented ears, the 7-year average yield favors the smooth type by a gain of 1.76 bu. per acre.

"Seed ears averaging 88.16 per cent grain have given a 6-year average yield of 64.64 bu. of shelled corn per acre, as compared with a yield of 65.06 bu. from ears averaging 76.38 per cent of grain. A comparison of kernels from the butt, middle, and tip portions of ears shows only 0.57 of a bushel difference in yield, as a 9-year average, and no difference in maturity or any important character. Seed ears having 14, 16, and 18 rows of kernels have been compared for 5 years. The 14-rowed ears have led slightly in yield at Wooster and Germantown, the 16-rowed ears at Carpenter.

"While the height of plant and ear varies with the season, selecting for high and low ears within a variety has resulted in changing very materially the relative height of ear and also the time of maturity. Low ears are associated with earliness. The comparative yield has not been reduced by selection for low ears.

"Seed corn grown on rich, as compared with poor soil, and one plant per hill, as compared with five, though larger and apparently of better quality, has not given any larger yield, on the average, than the smaller ears grown under the poorer conditions. The principal causes of barren plants are variations in season, in fertility, and in time and rate of planting. Such variations in conditions of growth have increased the amount of barrenness 200 to 2,000 per cent. Ear-row tests and subsequent crossing of the best ears in isolated breeding plats show possibilities of increasing the yield of corn 5 to 10 bu. per acre, but it seems difficult to go much beyond this amount. Of 13 first-generation crosses grown beside both parents, only two exceeded in yield the better parent variety by more than 2 bu. per acre.

"A 4-year average gain of 3.9 bu. of shelled corn per acre has resulted from the use of the individual ear germination test. At 50 cts. per bushel for corn, this is a return of \$6.50 per hour for testing. Experiments in thinning corn show a 4-year average gain of 8.47 bu. per acre in the case of untested seed and 6.31 bu. for tested seed. The average time required for thinning an acre of corn has been 5.7 hours.

"As an average of 6 years' tests corn reached its maximum shrinkage August 1. Based on shrinkage alone, 62.47 cts. for 70 lbs. of ear corn August 1 is equivalent to 50 cts. November 1. While mid-season and late varieties had 24, 29, and 31.04 per cent of moisture, respectively, November 1, on August 1 they carried 10.08 and 10.69 per cent, respectively."

Fertilizer experiments with corn on Piedmont Cecil sandy loam soil, and varieties, culture, and fertilization of corn on Piedmont Cecil sandy loam, red clay, and valley soils, C. B. WILLIAMS, B. W. KILGORE, and A. R. RUSSELL *North Carolina Sta. Bul. 229 (1915), pp. 50*.—In this bulletin experimental plats with their treatments are described and the weather conditions are also given for the years 1902 to 1909, inclusive.

A general summary of the results of fertilizer experiments with corn on the Cecil sandy loam and clay loam for this period is given as follows:

"The use of a mixture carrying normal amounts of phosphoric acid and nitrogen gave an average increased yield of shelled corn per acre of 69 per cent over the yield secured on the same character of land without fertilization. The net profit, over cost of fertilizer, of this combination was \$6.60 per acre.

"Where a normal amount of potash was used with phosphoric acid in place of the nitrogen there was an average decrease in yield of 8½ per cent of shelled

corn. The average profit for the P K application over cost of fertilizer was \$6.17 per acre.

"On an average a fertilizing mixture carrying normal amounts of nitrogen and potash was used with only a very small gain in yield and at a loss of 86 cts. per acre. Nitrogen, phosphoric acid, and potash combined in a complete fertilizer yielded on an average slightly less than when the potash was left out of the mixture. The experiments, as a whole, show that phosphoric acid and nitrogen are the predominant or controlling plant food constituents for increasing yields and adding to profits in growing corn on this soil."

Lime alone was used at a very small profit, while in a complete fertilizer the gain in yield was equal to a profit of 86 per cent. "Taking all the results as a whole, the indications are that in growing corn on this soil under similar conditions to those obtaining in these experiments, lime will generally be needed for the largest yields and greatest profit per acre."

The amount of nitrogen in the normal fertilizer applied was 3 per cent or 9 lbs. to the acre. When this amount was varied so as to give $4\frac{1}{2}$, 9, 18, and 27 lbs., the larger the amount of nitrogen the greater was the yield and profit per acre. The average yield of corn during eight years on the plats receiving three times the normal quantity of nitrogen with normal quantities of phosphoric acid and potash (N₃P K) was 24.4 bu. per acre and the average increase over unfertilized plats 15.2 bu. This fertilizer application cost \$7.35 per acre, making the cost of fertilizer per bushel of increase of corn 48 cts.

The amount of potash in the normal fertilizer used was $1\frac{1}{2}$ per cent or $4\frac{1}{2}$ lbs. per acre. This amount was varied so as to apply $2\frac{1}{2}$, 9, and $13\frac{1}{2}$ lbs., respectively. The results for the two fields were not in agreement, since in one the half-normal potash and in the other the twice-normal application of potash were indicated to be the most profitable amounts of this constituent to use.

The amount of phosphoric acid in the normal fertilizer used was 7 per cent or 21 lbs. of phosphoric acid per acre. This quantity was varied so as to apply $10\frac{1}{2}$, 42, and 63 lbs., respectively. The results show the largest yields, increases, and profits per acre from the use of 42 and 63 lbs.

Varying the amounts of the normal fertilizer application from 150 to 900 lbs. per acre gave increased yields and profits for all the applications, the most profitable returns on an average resulting from 150 lbs. of fertilizer per acre. After paying for the fertilizer itself the following respective profits were obtained: With 150 lbs., \$7.88 for corn and stover; with 300 lbs., \$5.21; with 450 lbs., \$6.94; with 600 lbs., \$6.49; and with 900 lbs., \$5.64.

In comparisons of dried blood and nitrate of soda as sources of nitrogen, the total yields and increased yields over unfertilized plats were quite uniform in showing a slight advantage in favor of the latter. Better profits were secured when the nitrate was divided, applying one half at planting with the acid phosphate and manure salt and reserving the other half and applying as a side dressing about July 1. Stable manure showed up particularly well on this soil as a source of nitrogen for corn.

When 300 lbs. of fertilizer was applied in the drill at the ordinary depth; in the drill about 4 or 5 in. below the seed; broadcast before planting; and, divided into two equal parts, one half being applied in the drill before planting and the other as a side dressing about July 1, the deep application and dividing the applications gave the largest yields and profits per acre.

Our soil analyses of the various soils of the State indicate that these results will apply to the red (Cecil) clay loams, red (Cecil) clays, and valley soils of the Piedmont, and in like manner the soil analyses and experiments on the mountain soils indicate that the results will apply to this section of the State also.

Saving hay crops, H. L. BLANCHARD (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 3, pp. 6-8).—This gives directions for curing and harvesting a hay crop under western Washington conditions.

The importance of thick seeding in the production of milo in the San Antonio region, S. H. HASTINGS (*U. S. Dept. Agr. Bul.* 188 (1915), pp. 21, figs. 9).—This bulletin reports and discusses experiments conducted to determine the effect of planting milo maize in rows at different distances apart and of thinning the plants to different distances within the rows on the tillering, branching, uniformity, date of ripening, and yield of grain.

The results obtained in 1913 and 1914 show that "no marked differences resulted in the number of tillers or the number of heads per plant from varying the distance between rows. In the plats where the rows were uniformly 4 ft. apart, but where the plants were thinned to different distances within the rows, the number of heads per plant decreased and the yield increased as the plants were crowded, the thicker stands producing the higher yields. Counts made of the number of tillers per plant on May 15 and of the number of mature heads per plant at harvest showed that a large number of tillers on the wide-spaced plants failed to produce heads.

"The close-spaced plants ripened their grain in 1913 about one week earlier than the wide-spaced plants. This early maturity is particularly important in that it permits the crop to escape the sorghum midge. Increasing the number of plants per row does not necessarily mean a proportionate increase in the total number of heads or stalks per row. The weather conditions influence very markedly the number of tillers and branches produced, although the total number of branches and tillers produced in 1914 about equaled the total number of tillers alone in 1913, when there were but few branches.

"In practice, the stand is controlled by varying the rate of seeding rather than by thinning the plants; thick stands are secured by thick seeding. Thicker seeding than is ordinarily practiced appears to be desirable, in that it results in smaller and more easily handled plant stumps, gives better stands, insures earlier and more uniform maturity, and produces better yields. A rate of 5 to 6 lbs. per acre, where the rows are 4 ft. apart, is recommended. It would appear that the close spacing of the plants can be practiced in sections of low rainfall. To offset this increase in the number of plants per row it is necessary only to increase the distance between the rows. The time the plants are thinned does not seem to be an important factor in suppressing tillers and branches. If the thinning is delayed sufficiently to reduce tillering, there seems to be a tendency for the plants to increase the number of branches."

Studies on oat breeding.—II, Selection within pure lines, F. M. SURFACE and R. PEARL (*Maine Sta. Bul.* 235 (1915), pp. 40, figs. 2).—This gives results of work with oats, the varieties having been previously described (*E. S. R.*, 31, p. 832).

"The present study attempts to analyze the results of three successive years of selection within pure lines of oats. Twenty-eight pure lines representing 13 varieties have been used in this work. In the four years 621 garden rows have been grown, involving over 12,500 plants. The characters studied were weight of grain, weight of plant and of straw, height of plant, and the number of culms. Only two characters, yield of grain and height of plant, are analyzed in detail in this paper. The remaining characters show essentially the same things.

"It is pointed out that the oat flower is practically always self-fertilized. It is shown that if this is true every oat plant must be regarded as homozygous for all of its characters. Consequently the oat plant fulfills all the requirements in the original definition of a pure line.

"The characters studied are subject to rather wide fluctuations, due to environment. For this reason it is not possible to compare the absolute values of these characters from year to year. Instead the deviations of the plants and rows from the mean of their pure line in the given year have been used. As a first approach to the problem in hand we have determined the number of rows, grown from plus selections, which deviated in the plus direction and likewise the number deviating in the minus direction. The same thing has been done for rows grown from minus selected plants. Thus for each selection there are four classes of rows. Also the sum of the deviations of the rows in each class has been determined and likewise the average deviation in each class.

"From these data for the yield of grain it is pointed out that usually in the next year following a given selection there is an excess deviation in the direction of the selection. This apparent effect of a given selection is very much less noticeable or not at all in the later years. It is probable that the effect in the first year is due to physiological rather than genetic causes. Considering the effect of two and of three successive selections in the plus direction it is seen that there is an excess deviation in the direction opposite to the selection. However, with two and three selections in the minus direction there is an excess in the direction of the selection. These results balance each other so that it appears safe to conclude that neither were due to the effect of the selection.

"The methods of analysis described above leave out of account two factors, viz, the difference in the variability of the different pure lines, and, second, the size of the deviation of the selected plant. The first of these factors can be partially taken into account by expressing each deviation as a percentage of its mean. The second factor can be accounted for by expressing the deviation of each plant as an index:

$$I = \frac{Dm - Dd}{Dm}$$

where Dm is the deviation of the mother plant from its mean and Dd is the deviation of the daughter row from its mean. If there is no effect of the selection, as Johannsen claims, then this index should on the average equal 1. If regression takes place within these pure lines, as claimed by the Galton-Pearson theory of ancestral heredity, the index would on the average approach 0.33. In general if the index is significantly less than 1 it indicates some effect of the selection.

"For the yield of grain, these indexes have been calculated for the effect of each selection upon the rows grown in each of the following years. The average index for each class of selection and for all the selections are given in [tabular form]. As shown in their probable errors these mean indexes are not significantly different from 1. This indicates that there is no effect of the selections within these pure lines. The mean indexes showing the effect of two or three successive selections in the same or in different directions are shown in [tabular form]. These indexes are also significantly equal to 1, with the possible exception of the successive minus selections. These latter indexes are consistently less than 1. Whether they really indicate an effect of the selections or not can not be determined from the present data. The values are not very far below 1, and in view of the other evidence we are inclined to regard them as random fluctuations.

"It is pointed out that where selections are made which are only slightly above or below the mean of their pure line, spurious values of this index are sometimes obtained. This is especially true if a relatively small number of rows are grown from such a selection. The reason for this is that the means of

some rows may deviate much farther from the mean of the line than did the mother plant. This will produce indexes very large either positive or negative. A priori there is no reason for excluding such small selections. They ought, on the selection theory, to result in rows which would deviate less from the mean of the line than rows grown from large selections. Only one such 'small' selection is included in the present data. The analysis of the selections for height of plant shows essentially the same results as found for yield of grain. Analysis by the method of deviations shows that in only one instance is the excess in the direction of the selection large enough to have any possible significance. For reasons discussed in the text it is probable that this one large deviation is not significant in connection with the selection. Indexes of selection for height of plant have been calculated for several of the selections. Since they show nothing essentially different from those for yield they have not been included in the present paper.

"On the whole the results obtained in this study give no evidence that selection for three years has modified any of the characters studied. The one or two apparent exceptions discussed in the paper might very easily arise in chance distributions where so small a number of years are considered. The weight of the evidence against an effect of selection far outweighs the evidence for such an effect. It must be concluded that in the present material and for the characters studied, selection for three years has produced no effect which can be detected by the methods used. It is proposed to continue a portion of these selections and later to attempt an individual analysis rather than the statistical one presented in this paper."

Peanut growing in the cotton belt, H. C. THOMPSON (*U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1915, Apr. 12, pp. 8*).—Cultural methods and uses of the crop are described.

Marketing Maine potatoes, C. T. MORE and G. V. BRANCH (*U. S. Dept. Agr., Off. Sec. Circ. 48 (1915), pp. 7*).—This reviews existing market conditions among the Maine potato producers. As factors in causing unsatisfactory prices, lack of comprehensive and efficient marketing systems and of established grades and brands as a basis for advertising are noted. As suggestions for improvement, the establishment of uniform grades and brands, the exercise of greater care in handling, thorough inspection, and the adoption of seed types, standards, and guaranties, are offered. Rules for grading are also suggested.

Potato growing in western Washington, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul., 1 (1914), No. 6, pp. 2-6, figs. 2*).—This gives cultural directions and methods of storage and marketing, together with descriptions of seven varieties that have given the best results in western Washington.

Lime-sulphur v. Bordeaux mixture as a spray for potatoes, III, M. T. MUNN (*New York State Sta. Bul. 397 (1915), pp. 95-105, pls. 2*).—The experiments described in this bulletin are in the main repetitions of those previously noted (*E. S. R., 28, p. 433*).

"The results agree essentially with those previously obtained. They show that lime-sulphur is harmful rather than beneficial to potatoes. Bordeaux mixture prevented tipburn to a considerable extent, made the foliage darker green, prolonged the period of growth, and increased the yield. Lime-sulphur, on the contrary, aggravated tipburn, dwarfed the plants, shortened the period of growth, and reduced the yield. As neither early blight nor late blight appeared in the experiment field during the season, nothing was learned concerning the comparative value of the different spray mixtures for the control of these diseases."

Lime-sulphur injurious to potatoes, F. H. HALL (*New York State Sta. Bul.* 397, popular ed. (1915), pp. 2, fig. 1).—A popular edition of the above.

Sudan grass, B. YOUNGBLOOD and A. B. CONNER (*Texas Sta. Bul.* 172 (1915), pp. 28, pl. 1, figs. 7).—This bulletin gives directions for the production of hay and seed from Sudan grass in Texas. Experiments indicate that to obtain the best results in hay production seeding should be done from April 15 to May 1 in cultivated rows not more than 18 in. apart and with not less than 7 lbs. of seed per acre, or in close drilled rows with from 15 to 40 lbs. per acre. The selection and breeding of the various types of Sudan grass are being carried out at the station.

In experiments for methods to follow in seed production it is shown that Sudan grass should be planted in cultivated rows only far enough apart to allow easy cultivation, sowing from 14 to 22 lbs. per acre.

Seed yields reported from the various substations range from 110 to 1,026 lbs. per acre. The percentage of seed to whole plant ranged from 10.4 to 23.7, with an average of 16.7 per cent in five tests.

A map shows regions in Texas where dependable seed crops of Sudan grass can and can not be grown.

Turnips as a stock food, C. D. WOODS (*Maine Sta. Bul.* 236 (1915), pp. 54-57).—In a cooperative field trial the average yield was 782 bu. per acre and the estimated cost \$59.05, or 7.6 cts. per bushel. It is concluded that rutabagas may be successfully grown to replace silage when it seems desirable to do so, although a ton of digestible dry matter can probably be grown cheaper per ton as corn.

The quality of home-grown versus imported wheat, R. STEWART and C. T. HIRST (*Utah Sta. Bul.* 137 (1915), pp. 63-76).—This bulletin gives results of tests with about twenty varieties of wheat. Analyses show the protein content of imported seed and home-grown grain, the yields and protein contents of flour, bran, and shorts, dry and moist gluten in the flour, expressed in percentages; ratio of wet to dry gluten; and the relation between the protein content of the wheat and the rainfall during the growing season.

The authors summarize the work, which covers a period from 1908 to 1912, inclusive, as follows: "As an average of five years' work it may be safely concluded that dry-farm wheat grown in Utah from imported seed does not decrease in quality. The five-year average protein content of the home-grown seed differs only by 0.1 per cent from that of the original seed, i. e., the protein content of the home-grown seed has remained practically constant, being influenced only by the varying climatic conditions from year to year. The five-year average result for the protein content of the wheat grown from the imported seed is 2.23 per cent greater than that of the original imported seed. Every variety of imported seed produced wheat the first year it was grown in Utah having a higher protein content than the original seed. In no year during the five-year period has any variety produced seed having as low a protein content as the original imported seed. . . .

"The practice of shipping in seed wheat is entirely unnecessary and wasteful. The quality of the home-grown hard wheats is really superior to the original seed. Good pure wheat seed should be selected of the kind the grower desires to raise. He should then continue to raise his own seed, and with proper selection he may rest assured that the quality of the seed will not become inferior, but he may have every confidence that his wheat is of superior quality."

Yellow-berry in wheat, its cause and prevention, W. P. HEADDEN (*Colorado Sta. Bul.* 205 (1915), pp. 3-38, pl. 1).—The author reviews in detail previous

work by various investigators along this line and gives results of his own work to discover the cause of the yellow-berry.

Fertilization with nitrogen, phosphorus, and potassium in single applications in the production of three varieties of wheat during 1913 and 1914 forms the basis of the following conclusions: "The appearance of yellow or white, mealy or half-mealy, or spotted kernels in wheat, otherwise without apparent blemish and known as yellow-berry is not due to over-ripeness, nor to exposure after cutting, nor to the action of fungi, nor is it a 'tendency' heritable in the wheat, as has been claimed by different authors. We have no substantiation of the claim sometimes made that climatic conditions favorably influence the development of or cause yellow-berry. Yellow-berry can be very much lessened or entirely prevented by the application of a sufficient quantity of available nitrogen. Yellow-berry can be greatly intensified or increased by the application of available potassium. The application of available phosphorus has no appreciable effect upon its prevalence. Yellow-berry is not indicative of an exhausted soil, that is, one which will not produce abundant yields. Yellow-berry indicates that potassium is present in excess of what is necessary to form a ratio to the available nitrogen present, advantageous to the formation of a hard, flinty kernel. Yellow-berry should not be mistaken for or confused with black-ended berries or brown or other discolorations in the berries. These affections are not general affections as the yellow-berry is and are not produced by the same cause.

"Yellow-berry is under the control of the grower. If there be sufficient difference in the price of grain produced he can control it with a margin of profit. The means at his disposal for its control are (1) the judicious use of sodic nitrate, (2) the thorough cultivation of his soil with the application of nitrogenous manures, (3) a rotation of crops in which a clover and possibly other legumes precede the wheat, (4) fallow cultivation. These observations apply to all of our western soils, rich in potassium and relatively, not absolutely, poor in available nitrogen."

HORTICULTURE.

Summer treatment of greenhouse soil, W. J. and S. N. GREEN (*Ohio Sta. Bul. 281 (1915), pp. 53-68, figs. 7*).—This bulletin gives the results of experiments started at the station greenhouses in the fall of 1908 to determine the practical difference between various methods of treating the soil during the idle summer months. Suggestions are also given relative to sterilizing greenhouse soil, the preparation of sod compost and manure, the use of commercial fertilizers and lime, and the summer utilization of greenhouses.

The test of various methods of summer treatment was continued through six seasons. In one plat the soil was renewed each year; in another plat a manure mulch was applied after removing the spring crop; a wheat straw mulch was used on a third plat, both of the mulch plats being kept well watered during the summer; and a fourth plat was allowed to dry out. The manure mulch was worked into the soil previous to planting the fall crop, but most of the straw had to be removed as it had decayed but little. A covering of fresh manure was spaded into the dry soil previous to planting in the fall.

The new soil plat gave the best results with tomatoes followed by the manure mulch plat. The straw mulch plat showed a rapid decline in yields, and the dry plat not only gave the lowest yields but was the only one to show a seriously diseased condition of the plants.

The test of lettuce crops, however, gave different results. The weight of lettuce from new soil plats was less at any time than that grown on manure

mulch and dry plats. Hence it is assumed that lettuce can be grown continuously on well-manured old soil. The straw mulch plat showed a marked decrease in yield, indicating the lack of fertility.

No test was conducted with cucumbers but the authors cite some other experiments to show that the cucumber is as sensitive as the tomato, if no more so, to conditions prevailing in old well-manured soils in the greenhouse. The authors conclude that a summer manure mulch may not obviate the necessity of summer sterilization but, in part, it appears to answer that purpose.

Onions, spinach, cauliflower, and casabas, F. GARCIA and J. W. RIGNEY (*New Mexico Sta. Bul. 92 (1915), pp. 41, figs. 9*).—In continuation of previous cultural experiments with onions (E. S. R., 27, p. 438) the results are given of fertilizer tests conducted with Bermuda and Denia onions for three seasons. Concise directions are also given for growing onions by the transplanting method, which has been found to be the best and most economical. The results to date of cultural experiments with spinach, cauliflower, and casaba melons are also reported.

The fertilizer tests with onions have shown in general the value of fertilizers, and especially of nitrate of soda, in increasing the yields. The work with spinach was conducted with a view to determining its hardiness during the winter and general adaptability for local culture, as well as to test the different varieties. Practically all the varieties were hardy except the New Zealand, which was entirely killed during the winter. A calculated yield of 2 tons per acre was secured, the crop being planted the latter part of September and harvested during the latter part of February. Notes are given on the different varieties included in the test, together with a letter by C. E. Locke relating his experience in growing spinach.

In the work with cauliflower a number of varieties were tested, with special reference to the production of a late or fall crop of cauliflower. Half of each plat of each variety was fertilized with nitrate of soda. The data secured for each variety are presented in tabular form. The Erfurt and Snowball varieties matured a heavier crop and a larger percentage of heads than any of the others. The fertilized plants developed larger and heavier heads, but they were slightly slower in maturing than the unfertilized plants. A letter by P. W. Barker giving advice on growing and selling cauliflower is included.

Tests of casaba melons which have been conducted at the station during the past three seasons indicate that they require a hot and dry condition to grow to the best advantage. Too much and continuous rainy weather, especially if accompanied by hot and sultry days, may encourage mildew on the vines. It has been found that the melons grow too large as a rule, and the future work at the station will include an attempt to produce smaller varieties of casabas.

[Report of the] horticultural department, J. L. STAHL (*Washington Sta., West. Wash. Sta., Mo. Bul., 2 (1915), No. 10, pp. 13-19*).—Notes are given on variety and demonstration tests of orchard and small fruits and vegetables which have been conducted at the station during the seasons of 1913 and 1914, including lists of varieties which have proved to be the most promising.

A test of clean culture *v.* sod is being conducted in a young mixed orchard of pears, plums, and cherries by using alternate strips or plats of trees of the same variety in sod and cultivated soil. In the cultivated sections a soil mulch is kept during summer. A vetch cover crop is grown during winter and plowed under in the spring. The results thus far, as here briefly stated, show that the trees in the clean culture plats are larger and produce almost double the amount and size of fruit, although they were of the same size when the test was started. Cherries and plums color as well in the cultivated plats, but pears color better in the sod.

In connection with the work with bush fruits a number of crosses were made of raspberry and blackberry plants in 1909 and 1910. Over 600 seedlings secured from these crosses began fruiting in 1912, and the more promising raspberry and blackberry crossbreds have been planted out for further trial. One of the original blackberry crosses is so promising with respect to earliness that it has been used as a parent in crosses made during the past two years.

Rhubarb culture, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 12, p. 16).—Brief practical directions for growing rhubarb are given, consideration being given to the soil, propagation, and transplanting, tillage, forcing rhubarb, and varieties.

Recommended varieties of fruit for Idaho, C. C. VINCENT and G. J. DOWNING (*Idaho Sta. Bul.* 83 (1915), pp. 15, fig. 1).—In this bulletin the authors divide the State into eight districts and give lists of varieties of orchard and small fruits recommended for culture in each district. The principal varieties of apples are also considered with reference to their strong and weak points.

Standard varieties of tree fruits, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1913), No. 4, pp. 2-6, figs. 3).—Horticultural descriptions are given of a number of varieties of apples, pears, plums, and cherries which are adapted for both the home and the commercial orchard in western Washington.

Studies in fruit bud formation, J. H. GOURLEY (*New Hampshire Sta. Tech. Bul.* 9 (1915), pp. 80, pls. 9, figs. 13).—This paper comprises a progress report covering a period of seven years on studies of certain factors with reference to their influence on fruit bud formation. The work was started in 1908 in a Baldwin apple orchard which is receiving various cultural and fertilizer treatments. An outline of the orchard plats, together with the practical results of the various treatments for a 5-year period as measured by growth, yield, and size of fruit has been previously noted (*E. S. R.*, 31, p. 141). In the present report data dealing with the following factors are given and discussed: Nitrate formation, soil moisture, organic and inorganic matter content of the soil, the laying down of starch in the twigs, the relation of leaf area to buds formed, relation of rainfall to yield and growth, the influence of cultural treatments, and effect of commercial fertilizers. A résumé and bibliography is given of literature bearing on the formation of fruit buds and on the reserve food in plants, mostly in fruit trees.

Summarizing the results of soil studies which were conducted during the years 1913 and 1914, the author finds that apple trees carrying a heavy load of fruit will suffer materially when the moisture content of the soil drops to 6.5 or 7 per cent in sandy soil and 12 per cent in a loam soil. "The moisture under sod in this experiment has run a little higher than where clean culture is practiced. The moisture is higher where a green crop is plowed in annually than where clean culture is practiced.

"The formation of nitrates is greatly reduced in a sod orchard. Nitrification takes place much more rapidly where a leguminous cover crop is plowed in than where clean culture is followed. Nitrates are found in great abundance throughout the season where nitrate of soda is applied as a fertilizer, but it is entirely washed out or decomposed over winter. Calcium carbonate applied to the soil in question has augmented the formation of nitrates. It appears in this soil that nitrate formation of from 20 to 40 parts per million as an average for the growing season is essential for the maximum vigor of the trees and abundant fruit-bud formation, and that above this an excess will not of itself increase the growth of the trees or number of fruit buds formed."

With reference to the laying down of starch in the twigs, a heavier deposition of reserve food material in the storage tissues was found in the case of

alternate year bearing trees when the trees had formed fruit buds. As starch, this reserve is mainly found in the medullary rays and pith. An average of about 4 per cent greater specific gravity of the twigs and branches in winter condition was found where fruit buds were formed. A much larger leaf area is produced in the "off" year than in the bearing year, amounting to 2.08 sq. in. more per leaf in the trees studied.

Measurements taken of the total twig growth of trees in the various plats show a rate and amount of growth closely commensurate with the yielding power of the trees. The growth practically ceased by the first of July or earlier on most of the trees. A second growth the latter part of the summer is common in this orchard. This is accompanied by a second period of fruit-bud formation as is evidenced by the fruit buds formed on the terminus of the second growth.

No relationship could be traced between the rainfall of the growing season and the fruit-bud formation in this experiment through a period of several years. The plats where the moisture ran the lowest during the period of fruit-bud formation, coupled with good growing conditions earlier in the season, have produced the largest number of fruit buds.

The studies here reported indicate that the yield in the "off" year of the Baldwin trees can be materially improved by good cultural methods. Trees receiving cultivation and cultivation with cover crops have greatly increased their capacity for fruit-bud formation over trees standing in sod. The use of fertilizers in addition to cultivation and cover crops has not as yet increased the fruit-bud formation.

A striking difference in the individuality of the trees as regards yield has been observed, but the percentage of healthy normal trees showing a consistently low yielding character is very low.

Fertilizer experiments on apple trees at Highmoor Farm, C. D. Woods (*Maine Sta. Bul. 236 (1915), pp. 52, 53*).—A brief note is given on some fertilizer experiments being conducted at the Highmoor Farm in orchards that had been brought into good condition before the experiments started by cultivation and fertilization for a period of three years. In one experiment a number of Baldwin trees all received the same application of standard fertilizer and a portion of them received in addition nitrate of soda at the rate of 100 lbs. per acre. As far as has been observed the additional nitrate of soda has had no effect in forcing the trees into bearing.

Another experiment was begun in 1912 in an orchard of Ben Davis trees in which one plat has received no fertilizer for a period of three years; another plat has received annually a fertilizer, at the rate of 500 lbs. per acre, carrying 4 per cent nitrogen, 8 per cent available phosphoric acid, and 7 per cent potash; and a third plat has received 1,000 lbs. of the same fertilizer per acre. Thus far no results which could be attributed to the fertilizer have appeared.

Profits from spraying twenty-five Missouri orchards in 1914, W. L. HOWARD (*Missouri Sta. Bul. 124 (1915), pp. 185-285, figs. 5*).—In 1913 five cooperative apple orchards were sprayed by the University of Missouri, and in 1914 25 orchards were sprayed or the spraying was supervised. Practically 100 demonstrations were held in connection with the spraying which was conducted in 14 counties in the State. The demonstration orchards were sprayed from two to four times, and with one exception both Bordeaux and lime-sulphur were used to control diseases with arsenate of lead added to poison insects. In one orchard a comparative test was made of lime-sulphur, Bordeaux, soluble sulphur, arsenate of lead paste, Bordeaux-arsenate paste, and Pyrox, both with reference to their fungicidal value and their tendency to cause spray injury.

The spraying records secured in all the orchards are here presented in detail, special attention being given to the more extensive work of 1914.

Summarizing the results of the work as a whole, lime-sulphur and Bordeaux seem to be equally efficient in controlling apple scab, blossom end rot, and cedar rust. Bordeaux appears to be a hazardous material to use for the calyx spray, especially on varieties of the Ben Davis type and those having a light-colored skin, on account of the serious injury from spray burn which may occur. Soluble sulphur as at present found on the market is a dangerous material to use as a summer spray, since it is very apt to destroy the leaves and may kill the calyx of the apples, thus causing the fruit to decay. The injury was attributed to the setting free of a large amount of arsenic from the arsenate used in connection with the soluble sulphur for controlling insects. Two applications of soluble sulphur during the season of 1914 on Gano apples produced fruit with a luster or finish superior to that produced by lime-sulphur. At the same time fully 75 per cent of the leaves were caused to drop off. Where three applications were given from 10 to 25 per cent of the fruit was destroyed. Bordeaux-arsenate paste and Pyrox both proved to be good fungicides and insecticides but are apt to burn the fruit, especially the Ben Davis and Gano varieties. These materials are considered to be of special value where only a few trees are to be sprayed, but on a commercial scale the homemade Bordeaux is more satisfactory and less expensive. The result from spraying an acre of Jonathan trees with arsenate of lead paste alone indicates that the arsenate of lead reduced the diseases (cedar rust and scab) by one-half. At the same time the spray injury from using this material amounted to 87.8 per cent at harvest time. In view of the serious amount of spray injury recorded the author is inclined to believe that some accident, such as an admixture of Bordeaux, may have occurred when the mixture was made up. Hence the data are presented merely as a record. As an insecticide the dry or powder form of arsenate of lead appeared to give as good results as the paste when used in half the quantity of the latter by weight. The powder costs approximately twice as much per pound as the paste.

The cost of spraying with lime-sulphur and lead arsenate was 9.29 cts. per tree for each application. The cost of Bordeaux and lead arsenate was 6.67 cts. per tree per application. The total average cost of spraying with lime-sulphur and lead arsenate was \$5.56 per acre of 60 trees, while Bordeaux-lead arsenate cost \$4 per acre. Averaging all orchards and all materials used, the cost of spraying per tree for the season of 1914 was for the first application 6.6 cts., the second 13 cts., the third 9.5 cts., and the fourth 8 cts.

"Missouri orchardists are advised to spray their apple trees at least three times—before blooming, immediately after blooming, and ten days to two weeks later. For the first spray use lime-sulphur 3 gal. to 100 gal. of water or Bordeaux 6:6:100; second spray, lime-sulphur 3:100, plus 5 lbs. arsenate of lead paste; third, same as second, or Bordeaux 6:6:100, plus 5 lbs. arsenate of lead paste. Where bitter rot is bad, one or two more applications may have to be made with either lime-sulphur or Bordeaux."

Spraying and thinning notes, 1914, J. H. GOURLEY (*New Hampshire Sta. Circ. 17 (1915), pp. 4*).—In connection with other orchard work during the seasons 1913 and 1914 comparative tests were made of several brands of spray materials to determine their effects as summer sprays, with special reference to foliage injury. The results as here summarized show the superiority of commercial lime-sulphur and arsenate of lead as a summer spray over any other materials used. The foliage was entirely unharmed and remained clean and vigorous throughout the season. The fruit showed no burning effect what-

ever and was free from insect or fungus injury. The dry forms of arsenate of lead proved to be as satisfactory as a paste of arsenate of lead when used in solution with lime-sulphur. Soluble sulphur preparations, in which there appears to be no lime, caused the most injury to foliage and fruit. Some injury was also caused by Pyrox and Bordeaux. Taking the results of the two seasons as a whole, lime-sulphur and lead arsenate mixture was more successful in controlling fungus troubles and insects than either Bordeaux-lead arsenate mixture or Pyrox.

Thinning experiments were conducted in two apple orchards, four trees being thinned and two trees left unthinned as checks in each orchard. No data are given relative to financial returns from the thinning, but the results show a marked increase in percentage of number one apples. The time required for thinning each tree is given.

Spring and summer spraying for the orchard, H. L. REES (*Washington Stat., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 12, pp. 10-16).—A concise discussion of spraying methods, including spraying programs for spring, summer, and fall, for the control of orchard pests. Data are also given relative to the preparation of spray mixtures.

Spraying calendar, C. C. VINCENT and W. C. EDMUNDSON (*Idaho Sta. Circ.* 1 (1915), folio).—This calendar contains directions for the control of the more important insect pests and diseases of fruits and vegetables, including instructions for the preparation of spray mixtures.

Analyses of materials sold as insecticides and fungicides, C. S. CATHCART and R. L. WILLIS (*New Jersey Stat. Bul.* 273 (1914), pp. 3-13).—This bulletin contains analytic data on materials sold in New Jersey as insecticides and fungicides during the 1914 season. The materials examined included Paris green, lead arsenate, lime-sulphur solution, Bordeaux mixture, and a number of miscellaneous brands.

Systems of training berry canes, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1914), No. 7, pp. 3-8, figs. 3).—This article describes various methods of training red raspberries, high-bush blackberries, trailer blackberries, and loganberries.

Harvesting the berry crops, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 3, pp. 3-11).—This article contains practical suggestions relative to picking and packing raspberries, blackberries, loganberries, and strawberries.

Varieties of strawberries and raspberries, J. L. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1914), No. 5, pp. 2-6, figs. 2).—As a result of variety tests conducted at the Puyallup substation during the past three years horticultural descriptions are given of a number of strawberries and red raspberries adapted for culture in that region. Brief popular instructions are also given for planting strawberries and raspberries.

Strawberry growing in the South, H. C. THOMPSON (*U. S. Dept. Agr., Farmers' Bul.* 664 (1915), pp. 20, figs. 11).—A practical treatise on strawberry culture with special reference to southern conditions. Consideration is given to choice of location, propagation, soils for strawberries, fertilizers, systems of growing, planting operations, cultivation, mulching duration of plantation, renewing old beds, rotation, harvesting, packages, varieties of strawberries, cost of growing, and strawberry by-products.

Strawberry culture in Wisconsin, J. G. MOORE (*Wisconsin Sta. Bul.* 248 (1915), pp. 40, figs. 12).—A practical treatise on strawberry culture, discussing selection of site and soil, preparation of the soil, selection of plants, planting operations, and subsequent management of the plantation, including the renova-

tion of beds after harvest and strawberry pests. Data based on the opinions of some twenty growers are given relative to fertilizers used and varieties adapted for different soil conditions and for early, late, and main crop plantings.

Fertilizer tests with red raspberries, J. H. STAHL (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 7, pp. 6-8).—The results of fertilizer tests with red raspberries conducted under the direction of the Puyallup substation during the past three seasons indicate that farm manures are the best fertilizers for raspberries, and that manure applied in the fall gives quicker results than when it is applied during the spring. A complete commercial fertilizer appears to be more successful than an incomplete fertilizer.

[**Experiments with citrus seedlings in 1914**], **B. F. FLOYD** (*Florida Sta. Rpt.* 1914, pp. XXXV-XLV, fig. 1).—The author here presents the data for the first season of fertilizer experiments with potted grapefruit seedlings in which the soil used was a field soil with good humus content. The results are compared with those obtained in 1913 when the seedlings were grown in pure sand (E. S. R., 31, p. 742). The sand cultures were also repeated on the opposite side of the greenhouse from where the 1913 cultures were conducted. The results from the two seasons' work are compared. The experiment as a whole involves a determination of the effect of varying sources of nitrogen and phosphoric acid upon the growth of the seedlings. The results thus far secured are not considered as conclusive.

A survey of comparable data shows that in the soil experiments sulphate of ammonia gave the highest average growth among the nitrogenous materials, and that different sources of phosphoric acid showed few differences. In the 1913 sand cultures dried blood gave the highest average among the nitrogenous materials and basic slag the highest average among the sources of phosphoric acid. A curve representing the stem lengths of the plants grown in the field soil approaches much nearer a straight line than a curve representing the stem lengths of plants grown in pure sand, thus indicating much less variation from the use of the different fertilizers when used on a good soil than when used on a soil poor in humus and organic matter.

A comparison of the sand-culture results secured in 1913 and in 1914 shows that, although the individual series are not entirely duplicated, the general averages of the groups containing a common source of nitrogen or phosphoric acid are practically the same, dried blood and basic slag giving the highest average growth. Sulphate of ammonia was lowest in one series and nitrate of soda in the other. Acid phosphate used alone gave the poorest growth, but when lime was used with acid phosphate fully as good growth was obtained as from basic slag.

Citrus experimental grove, S. E. COLLISON (*Florida Sta. Rpt.* 1914, pp. LXXV-LXXVII).—In continuation of previous reports (E. S. R., 31, p. 742) measurements are given showing the average gain in diameter of trees from June, 1909, to June, 1914, growing on various fertilizer plats in the citrus experimental grove.

No definite conclusions are drawn from the results thus far secured.

[**Report of the horticulturist**], **W. H. LAWRENCE** (*Arizona Sta. Rpt.* 1914, pp. 349-351).—A brief progress report on the work for the year, including data on a test of processed fabrics as containers of heat for protecting citrus trees from frost.

In conducting the above test four trees were covered with tents of cotton fabric. The tents were constructed to inclose trees 10 ft. wide and 10 ft. high, exclusive of the trunk. Two of the tents were made of light and two of medium weight fabrics. One of the light weight and one of the medium

weight tents was processed with a material claimed to make the fabric mildew-proof; gas, water, and air tight; only slightly resistant to sunlight; and both heat absorbing and heat retaining. Lamps with tin chimneys were used at first, but proved unsatisfactory. No. 2 lanterns and lamps were then substituted.

Briefly summarized, the work indicates in a general way that the heavier processed fabric employed retains heat to an extent practicable for the protection of trees at a reasonable cost for fuel. The fabrics were not found mildew resistant or gas and water tight as claimed.

[Walnut growing in Arizona], J. J. THORNER (*Arizona Sta. Rpt. 1914, pp. 339, 340*).—The author announces that C. R. Biederman, of Garces, Ariz., has perfected a method of top-working Arizona walnut stocks which enables him to graft French and English walnuts on Arizona stocks at almost any season of the year. Several thousand native seedlings are to be grown in the plant introduction garden for testing this method, which is to be fully described in a publication soon to be issued by the station.

Tree troubles at Douglas, Arizona, J. J. THORNER (*Arizona Sta. Rpt. 1914, p. 341*).—Preliminary results from an examination into the causes affecting the growth of ornamental trees and shrubs at Douglas, Ariz., indicate that some of the more common troubles are bad drainage and soil aeration, due to poor methods of planting, selection of varieties unsuited for local conditions, damage to foliage from smelter smoke and fumes, and also black alkali in the irrigation water. Lists are given of trees which do and do not grow well with reasonable care both at Douglas and generally throughout the State.

FORESTRY.

Annual report on the progress, literature, and important happenings in the realms of forestry, hunting, and fishing for the year 1913, H. WEBER (*Allg. Forst u. Jagd Ztg., 1914, Sup., pp. VIII+216*).—In continuation of previous reports (*E. S. R., 30, p. 238*), this supplement contains abstracts of the more important world literature dealing with various phases of forestry, together with notes on the principal occurrences relating to forestry, hunting, and fishing during 1913.

Pennsylvania trees, J. S. ILLICK (*Harrisburg: Pa. Dept. Forestry, 1914, pp. 231, pls. 164*).—Part 1 of this work is intended for the layman and beginner of forestry and comprises abstracts from the author's lectures on elementary forestry at the Pennsylvania State Forest Academy. Part 2 is essentially a manual of Pennsylvania trees. It comprises a discussion on the identification of trees and a description of families, genera, and species with accompanying keys.

The cypresses, A. CAMUS (*Les Cyprés. Paris: Paul Lechevalier, 1914, pp. 106, pls. 4, figs. 424*).—A monograph on the genus *Cupressus*. It comprises a general account of the external and internal morphology of the genus, a study of the stability of its characters, a classification of the genus, and descriptions of the various species and varieties with reference to their bibliography, synonymy, distinguishing characteristics, anatomy, habitat, geographical distribution, culture, and uses. A bibliography of cited literature is appended.

[Eucalypt yields], A. M. McOMIE (*Arizona Sta. Rpt. 1914, p. 333*).—A comparison of clean-cutting yields from a 12-year-old and a 6-year-old grove of *Eucalyptus rudis* indicates that the increased number of ties, posts, and stove wood secured to the older grove was not sufficient to warrant the delay of six years in cutting. One hundred and thirteen 12-year-old trees yielded 16,175

lbs. of ties, 17,125 lbs. of posts, and 4,450 lbs. of stove wood, as compared with 10,145 lbs. of ties, 16,190 lbs. of posts, and 6,125 lbs. of stove wood from 91 6-year-old trees.

Some preliminary investigations with regard to the cultivation of the black locust in southeastern Indiana, G. CULBERTSON (*Ann. Rpt. Ind. Bd. Forestry, 14 (1914), pp. 67-72, figs. 5*).—Preliminary observations on several locust plantings in southeastern Indiana led the author to conclude that many thousand acres of hill lands rich in lime and subject to serious loss by erosion should be planted to locust trees, and that the profits from such plantings would prove highly satisfactory.

Rubber in Brazil, O. LABROY and V. CAYLA (*A Borracha no Brazil. Rio de Janeiro: Min. Agr., Indus. e Com., 1913, pp. V+153+XX, pls. 38, figs. 52*).—A report on the exploration, preparation, marketing, and commerce of various forms of Brazilian wild rubber, together with an account of methods employed in the culture, tapping, and preparation of plantation rubbers in tropical Asia. The introductory part contains economic considerations on the world's production of rubber and summarizes the various sources of rubber. The succeeding parts deal with Hevea, Manihot, Castilla, and Hancornia rubbers.

International Rubber Congress and Exhibition, Batavia, September, 1914.—Rubber Book, edited by C. J. J. VAN HALL (*International Rubber Congress met Tentoonstelling, Batavia, 1914. Rubber Recueil, Amsterdam: J. H. de Bussy [1915], pp. X+609, pls. 5, figs. 70*).—This work, which was prepared on behalf of the congress committee, comprises a series of papers by various authorities on the rubber-producing plants, their culture, the preparation of raw rubber, and commerce. The various articles are grouped under the general headings of botany and phytopathology, climate and soil, cultivation and tapping, preparation and chemistry of rubber, economic questions, and commerce.

Chinese forest trees and timber supply, N. SHAW (*London: T. Fisher Unwin, 1914, pp. 351, pls. 34*).—Part 1 of this work takes up the physical and climatic conditions in China, contains a general description of the forests, and discusses the forest problem of China. Part 2 contains notes on broad-leaved trees, conifers, bamboo, palms, and foreign trees with reference to their range, adaptation, and economic uses. Information relative to rafting operations and timber imports into China and notes on timber in use by Chinese railways are appended.

Production and value of Irish timber, A. C. FORBES (*Dept. Agr. and Tech. Instr. Ireland Jour., 15 (1915), No. 2, pp. 338-346*).—A statistical survey of Ireland's timber resources with special reference to the uses and markets for native timbers.

Of the total area of the country only 297,809 acres, or 1.4 per cent, is under woods. The rates of cutting and of planting during the past 10 years show a deficiency of 4,341 acres in the planted area necessary to maintain a permanently stocked acreage of woodland.

Manuring experiments on Castleton Estate, Telok Anson, M. BARROWCLIFF, B. BUNTING, and F. G. SPRING (*Agr. Bul. Fed. Malay States, 3 (1914), No. 3, pp. 111-114*).—In 1913 experiments were started with some 3,500 3-year-old rubber trees to determine the possible value of nitrogen, potash, and phosphoric acid used alone and in various combinations in stimulating growth and yield. Growth measurements for the first season as here presented show no decided influence from the various treatments. The experiments are to be continued.

Report of the director of forests, N. W. JOLLY (*Ann. Rpt. Dept. Pub. Lands Queensland, 1913, pp. 47-51, pls. 3*).—A report on the administration, management, and exploitation of the state forests in Queensland during the calendar year 1913.

DISEASES OF PLANTS.

Plant diseases, E. PRILLIEUX (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 9-12*).—This is a portion of the phytopathological report for 1912, and deals briefly with some diseases of cereals, tubers, crucifers, legumes, vines, and orchard and forest trees, as noted in various parts of France.

Plant pathology, H. TRYON (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, pp. 117-119*).—Notes are given on a number of plant diseases of agricultural and horticultural crops, and a synopsis is presented of the Diseases in Plants Act of 1896 and the inspection carried on under this act.

Studies on Orobanche, F. GUÉGUEN (*Min. Agr. [France], Ann. Serv. Éptiphyties, 1 (1912), pp. 433-436*).—This is a brief preliminary study of the effects due to *O. minor*, parasitic on clover and parsnip in parts of France. The tuberous modifications of the subterranean parts in the case of parsnip are compared with those noted in rootlets of grape stocks attacked by phylloxera.

Foot rot of cereals, A. MOREAU (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 437-440*).—The results are briefly reported and discussed of an inquiry circulated among grain producers requesting information regarding foot rot or stalk disease of cereals in parts of France, particularly in the Paris Basin.

Meteorological conditions seem to play an important part, particularly those permitting growth of the crop in winter or early spring. Excessive nitrification also apparently favors the activity of fungi. Early seeding (September and October) appeared more favorable to the development of the fungi than later (November to spring). Variety is significant in this connection, a degree of relationship existing among several of the varieties most susceptible to foot rot. The influence of previous croppings appears to be twofold, affecting the chemical composition of the soil and the biological conditions (as lateness of season, etc.).

Protective measures suggested include the choice of resistant varieties, late seeding, rotation with reference to period of the year occupied by the crops, destruction of stubble, and use of fungicides.

Smut disease in maize (Queensland Agr. Jour., n. ser., 2 (1914), No. 6, pp. 400, 401).—This is a brief account of the appearance of *Ustilago maydis* on Indian corn near Toowoomba in 1914, with a brief discussion of its dissemination and of its control by the removal of all affected stalks before the breaking of the smut tumors, the nonuse of such plants for feeding, and the nonuse of affected land and land over which prevailing winds or wash may carry the spores.

Winterkilling of wheat, E. SCHAFFNIT (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg, 1913, pp. 21-23*).—Studies with wheat varieties are said to have shown that the seed when subjected to different low temperatures for different periods showed an increase of injury corresponding to the increased duration and lowering. Plantlets were ordinarily injured very little at from -5 to -10° C., but considerably at -15 to -20° . The young growing points showed considerable resistance, owing presumably to the presence of bud scales and the colloidal condition of certain cell contents, this portion thus determining the fate of the plant. The fact that roots are less subject to temperature extremes than are aerial portions insures supplies to the aerial parts as soon as the temperature permits utilization thereof.

Frost is thought to influence the sprouting of the grain, but just how has not yet been determined, and this is true also of the chemical changes in chilled plants. Resistance to cold by some varieties seems to show a relation to the water content, and it also appears to be true that an increase of water content renders the plant more sensitive to outside influences. Nocturnal frosts seem to render the stems liable to breaking, and chilling affects the heads also in ways not fully understood.

Studies of club root.—II, Disease resistance of crucifers; methods of combating club root. G. C. CUNNINGHAM (*Vermont Sta. Bul. 185 (1914)*, pp. 67-96, pls. 8).—This bulletin is the second on club root studies (E. S. R., 31, p. 642).

In the present publication the author gives the results of observations on the susceptibility of different cruciferous plants to club root, and it was found that the great majority, if not all crucifers, were more or less susceptible. Cabbages showed variety resistance, a number of varieties being somewhat less subject to attack than others.

Radishes showed a wide range of susceptibility, and in case of turnips and rutabagas the rate was even greater than in cabbages or radishes. In this wide range of susceptibility the author believes that satisfactory means of combating the disease may be found.

An examination of many thousands of plants, including 28 genera and 104 species, led the author to describe 6 types of hypertrophy which are more or less characteristic of certain crucifers.

For the control of the disease the application of lime, preferably air-slaked lime, at the rate of 150 bu. to the acre, greatly increased the production of marketable cabbage. The lime to be effective should be thoroughly worked into the soil to a depth from 6 to 9 in. In 1912 experiments showed that hilling up about cabbage stalks caused the formation of adventitious roots and materially increased the crop, but in 1913 no beneficial results were obtained, possibly on account of the dry season.

A bibliography is given.

Studies on potato anatomy, VON TIESENHAUSEN (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg, 1913*, pp. 23-25).—A brief discussion is given of studies in progress, the results of which thus far as related to phloem necrosis in the potato are said not to be in complete agreement with the conclusions announced by Quanjer (E. S. R., 29, p. 347).

Diseases of potatoes, II, III, H. L. REES (*Washington Sta., West. Wash. Sta. Mo. Bul., 1 (1914)*, Nos. 6, pp. 9-16, figs. 7; 7, pp. 14-16).—Popular descriptions are given of Rhizoctonia or little potato disease, potato wilt or dry rot, blackleg, silver scurf, scab, powdery scab, internal brown spot, and internal cracking of the potato, with suggestions for their control.

The spindling-sprout disease of potatoes, F. C. STEWART and F. A. SIRRINE (*New York State Sta. Bul. 399 (1915)*, pp. 133-143, pls. 3; *abs. in Phytopathology, 4 (1914)*, No. 6, p. 395).—Attention is called to the fact that Long Island potato growers in 1914 who planted their fields with home-grown seed secured a poor stand, many of the plants being small and weak. The seed pieces did not rot prematurely and there was no spotting, rolling, or curling of the leaves, or other pathological symptom. The tubers used for seed purposes were small, but otherwise normal in appearance.

Examination of unsatisfactory stands showed that weak plants and missing hills were in most cases due to using, for seeds, tubers which produced slender thread-like sprouts. This trouble is considered due to a weakened or debilitated condition of the seed tubers and is thought to be a result produced by the excessively hot weather in the summer of 1913.

It is suggested that Long Island potato growers using home-grown seed should make a sprouting test of their seed potatoes.

Morphology and cytology of the sexual organs of *Phytophthora erythro-septica*, P. A. MURPHY (*Ann. Bot. [London]*, 28 (1914), No. 112, pp. 735, 736).—A preliminary account is given of morphological and cytological studies on *P. erythroscptica*, recently described as causing a disease of potatoes (E. S. R., 29, p. 550).

The physiology of *Phoma betæ*, W. FISCHER (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg*, 1913, p. 28).—Experimentation showed that *P. betæ* can sustain a temperature of -20° C. for 48 hours. Cultures subjected daily during two or four weeks to temperatures ranging from 0 to -10° were not killed by the cold. Tests with preparations in use as sprays showed that while copper sulphate, formalin, and carbolic acid in the concentrations and durations usually employed are ineffective as against *P. betæ*, corrosive sublimate and chinolol quickly show strong fungicidal action against this fungus, checking growth in concentrations as low as 1:10,000, but having no injurious effects on the beet seed under treatment.

Black spot of the tomato, G. P. DARNELL-SMITH (*Agr. Gaz. N. S. Wales*, 25 (1914), No. 12, pp. 1069, 1070).—According to the author the black spot of tomato is widely spread in New South Wales, probably causing more loss than any other tomato disease.

A study of the trouble has led him to believe that both bacteria and fungi are concerned in the black spot. The sequence of events in the production of the spots would appear to be injury to the skin, entrance of bacteria, and infection by *Macrosporium*. There is believed to be evidence that the fungus alone is capable of producing typical black spot. The disease is considered largely dependent upon drought conditions, and where tomato plants are adequately shaded and watered the trouble may be very much reduced. If it is considered desirable, in addition to providing an adequate water supply, the plants may be sprayed with Bordeaux mixture or lime-sulphur solution, the application of the fungicide assisting in checking the tomato leaf spot due to *Septoria lycopersici*.

Black hearted turnips, C. D. WOODS (*Maine Sta. Bul.* 236 (1915), pp. 57-59).—The attention of the station was called to a serious trouble of turnips, in which the roots were perfect on the outside, skins bright and smooth, but when cut the flesh had large patches of a dull-brown color, the discoloration extending nearly to the skin. An examination of diseased material showed that the black heart was not produced by fungi or bacteria, but was apparently a condition arising from some factor or factors in the growth of the plant. A demonstration experiment was carried on to determine the relation of fertilizers and varieties to this disease.

The results obtained are not considered definite, but they indicate that there is a difference in varieties in regard to their susceptibility to the disease and that the plants to which stable manure was added had less of the trouble than the others.

Fire blight of pear and apple, H. L. REES (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1913), No. 4, pp. 6-9, figs. 7).—A popular description is given of the bacterial blight of pears and apples, with suggestions for its control.

Blight resistance in pears and pear stocks, F. C. REIMER (*Mo. Bul. Com. Hort. Cal.*, 4 (1915), No. 3, pp. 145-149, fig. 1).—Attention is called to the resistance of certain species and varieties of pear-tree stock to pear blight.

Among the species reported upon it is said that Japanese pear stock (*Pyrus sinensis*) and stock of a species from China (*P. betulifolia*) have been success-

fully grown and seem to be resistant to blight, and their use is recommended in combating this disease. In addition the author suggests the top-working of blight resistant trees on the stocks mentioned above, on Kieffer, or on some other varieties which are superior to Kieffer, as a means for combating this trouble, which is exceedingly destructive in the orchards of the Pacific coast.

Plum diseases, E. RABATÉ (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 177-185, figs. 6*).—This includes a discussion of some insect enemies found on plum trees, also of plum leaf rust (*Puccinia pruni*), plum rot (*Monilia cinerea*), and some degenerative changes in portions of the trees affected, with suggestions regarding possible control.

A parasitic disease of quinces, H. BLIX (*Rev. Hort. [Paris], 86 (1914), No. 8, pp. 182, 183*).—A description is given of a disease of quinces first observed in France in 1913, and which has since been found in a number of localities.

The trouble is said to be due to *Monilia fructigena*, which attacks the leaves and young fruits. The fruits are mummified, and it is suggested that for the control of the disease all fallen leaves and mummy fruits be collected and burned and the plants sprayed with Bordeaux mixture.

Experimental spraying for blackberry anthracnose, H. L. REES (*Washington Sta., West. Wash. Sta. Mo. Bul., 2 (1914), No. 6, pp. 2-12, figs. 5*).—A preliminary report is given of spraying experiments in three fields for the control of the blackberry anthracnose.

This disease is said to be supposedly troublesome in western Washington and it is considered that it is probably caused by the same fungus as that occurring on the blackberry in the East (*Glaosporium venetum*), although this has not been demonstrated. The disease differs in some respects in that the principal damage caused by the fungus in western Washington is on the berries. The girdling and killing of the canes, which is a prominent symptom of anthracnose in the East, is said not to occur in Washington, but the fruiting stems are girdled and killed, causing considerable loss.

In 1913 experiments for the control of the disease were carried on in which it appeared that Bordeaux mixture, lime sulphur, and Burgundy mixture gave the best results. Cutting out canes as soon as the fruit is picked will also lessen the amount of disease. The author considers it doubtful whether fall spraying is advantageous. Spraying during the growing season will reduce the amount of loss, and it is considered that the most effective time for spraying is immediately after the petals have fallen.

Mulberry diseases, G. ARNAUD (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 220-227, figs. 3*).—This contains a brief description of the stages of *Nectria cinnabarina* on mulberry, with recommendations regarding the control of the fungus, including selection of stock, use of sprays in early spring, and removal of portions showing attack. A second disease is also described, due to a fungus, producing a discoloration in the spring wood which it invades.

A study of chlorosis in grape stocks, P. MARSAIS (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 413-420*).—This is an account of a series of experiments on the development by crossing of vines resistant to phylloxera and at the same time commercially successful in the calcareous soils, which in these districts tend to produce chlorosis in stocks of foreign origin. The results obtained are thought to justify the hope that in spite of the climatic, soil, and biological obstacles existing in this region, particularly those presented to foreign stock, the problem of continuing profitable grape culture in this region may be regarded as capable of solution by employment of hybrids named as having been found best adapted to the conditions there existing.

Grape mildew, L. RAVAZ (*Min. Agr. [France], Ann. Serv. Epiphyties, 1 (1912), pp. 392-398, figs. 2*).—This contribution deals with the relations between soil surface conditions and the development of *Plasmopara viticola*, reporting also some experiments with fungicides.

Some experiments in treating citrus trees for gummosis and heart rot, J. A. PRIZER (*Mo. Bul. Com. Hort. Cal., 4 (1915), No. 1, pp. 7-19, figs. 7*).—A description is given of the brown rot gum disease of the lemon, due to *Pythiacystis citrophthora*, and the gray fungus gummosis, caused by *Botrytis vulgaris*.

In addition an account is given of successful experiments for the control of these diseases, which consisted in cutting out the diseased bark and painting the area over with Bordeaux paste. This has been practiced for some time for the treatment of the brown rot at an annual cost of about 7 cts. per tree in a block of over 18,000 trees. Similar results have been obtained for the control of the *Botrytis* disease.

Report of plant physiologist, B. F. FLOYD (*Florida Sta. Rpt. 1914, pp. XXX-XXXV, fig. 1*).—In a study of the relation of the water table to die-back of citrus trees, conditions were produced that were believed to be similar to those in groves lacking drainage. Tanks were arranged in series, in the first series of which the water table stood 7 in. from the soil surface, in the second 14 in., and in the third the soil was kept moist to the bottom of the tank without allowing saturation. Orange trees of uniform size, appearance, and thrift were planted in these tanks in 1912, and the resulting growth has been measured and analyzed.

It was found that the types of growth produced were not at all the same that characterize trees which develop physiological disturbances known as die-back. It is concluded, therefore, that the experiment did not exactly reproduce the field conditions known as lack of drainage, which is held to cause this disease.

Report of plant pathologist, H. E. STEVENS (*Florida Sta. Rpt. 1914, pp. LVII-LXXIV*).—Field studies, infection experiments, and experiments for the control of gummosis are reported upon, most attention being given to the form of gumming which is commonly known as gummosis, a brief description of which has been given (E. S. R., 19, p. 654). Two types of this disease are recognized, one of which attacks the trunks, larger branches, and smaller twigs, while the other occurs only on the trunks and larger branches.

The cause of gummosis has not been definitely established, although several fungi are found associated with it. Observations have been made on the development of diseased areas, which indicate that the development of the disease is slow and that there are active and passive phases associated with this development. Inoculation experiments were made with diseased tissue inserted in healthy trees, but no definite conclusions are drawn from the results. It is thought that probably young trees are more resistant to the disease than older bearing ones. Some control experiments are briefly reported, in which the diseased portions of the tissues were cut out and treated with antiseptics. For this purpose Bordeaux paste was found fairly effective.

The investigations with melanose were continued, and the inoculation experiments showed that *Phomopsis citri* is the cause of both the stem-end rot and melanose (E. S. R., 31, p. 750). It is stated that severe outbreaks of stem-end rot occurred in different localities during the season, and this is believed to be due to the unusual development of the fungus in dead citrus twigs.

A brief report is given on the citrus canker, a preliminary but more detailed account of which has been issued by the station (E. S. R., 31, p. 54). It is

stated that a species of *Phyllosticta* has been isolated from infections on grapefruit leaves.

Die-back of citrus trees in the northern districts, G. WILLIAMS (*Queensland Agr. Jour., n. ser., 3 (1915), No. 1, pp. 22, 23*).—Attention is called to the prevalence of die-back of citrus trees in the northern districts of Queensland and to the fact that spraying has failed to control the trouble.

The author suggests that among the causes of the disease are unsuitable soil conditions and that trees may be kept in a healthy condition by sufficient depth and drainage of the soil, with an even supply of moisture, obtained principally by systematic cultivation.

Diseases of the peony, H. H. WHETZEL (*Amer. Florist, 44 (1915), No. 1401, pp. 609-612, figs. 7*).—In this paper the author presents a summary account of diseases of the peony, describing their symptoms, causes, and methods of control.

Although this plant is frequently reported as free from disease, the author describes root gall, due to *Heterodera radicolica*, and root rots, the cause of which is not known; mosaic disease; anthracnose, which is considered due to a fungus as yet unidentified; leaf blotch, caused by *Cladosporium paoniae*; *Sclerotinia* stem rot, due to *S. libertiana*; and *Botrytis* blight, which has been referred to a number of species, but which the author's studies indicate is due to at least two distinct species of *Botrytis* causing identical symptoms.

Diseases of oak and chestnut in Brittany, V. DUCOMET (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 87-105*).—This is a somewhat detailed account of studies with *Oidium* and other fungi on oak, also of *Melanconis modonia* and other fungi on chestnut.

Chestnut disease in France, L. MANGIN (*Min. Agr. [France], Ann. Serv. Épiphyties, 1 (1912), pp. 80-86*).—A recent increase of injury by *Melanconis modonia* in parts of France is noted. *Diaporthe parasitica*, where it exists in Europe, is said to be neither so abundant nor so formidable as in America. Iron sulphate and copper sulphate have been proposed as means of protection against *M. modonia*.

Air and wind dissemination of ascospores of the chestnut blight fungus, F. D. HEALD, M. W. GARDNER, and R. A. STUDHALTER (*U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 6, pp. 493-526, pls. 3, figs. 3*).—A detailed account is given of investigations on the dissemination of the ascospores of the chestnut blight fungus (*Endothia parasitica*) by air and wind. All the experiments carried out point to air and wind transportation of the ascospores of the chestnut blight fungus as one of the very important methods of dissemination.

After every warm rain ascospores are scattered from diseased trees in large numbers, having been collected from 300 to 400 ft. from the source of supply. The authors believe that they have been carried much greater distances. During dry periods wind dissemination of ascospores does not occur at all, or only to a very slight extent.

Witches' brooms on British willows, M. CHRISTY (*Jour. Bot. [London], 53 (1915), No. 628, pp. 97-103, pl. 1*).—The author gives a description of witches' brooms on willow trees which have appeared within recent years. The trouble seems to be spreading, although confined to a rather limited area about London. The abnormal growth is attributed to the gall mite, *Eriophyes triradiatus*, and the witches' brooms seem to be produced originally from female flowers which have become excessively hypertrophied.

Estimating nematodes, BAUNACKE (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg, 1913, pp. 28-30*).—A modification is described of methods formerly employed, according to which these organisms are separated from soil taken at desired depths, stained, and fixed for counting at convenience.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Revision of the American marmots, A. H. HOWELL (*U. S. Dept. Agr., Bur. Biol. Survey, North American Fauna No. 37 (1915), pp. 80, pls. 15, figs. 3*).—The American marmots, more often called woodchucks or ground hogs, are naturally divided into three distinct groups: (1) The woodchucks (*Marmota monax* group) of eastern United States and Canada; (2) the yellow-footed marmots (*M. flaviventris* group) of western United States and southern British Columbia; and (3) the hoary marmots (*M. caligata* group), chiefly restricted to the higher mountains of western North America.

Following the introduction the author discusses their history and nomenclature, vernacular names, habits, economic status, external characters, material examined, the genus *Marmota*, etc. Descriptions are given of 26 forms, together with a series of maps which show their geographic distribution. In many localities they are a decided pest to agriculture, especially in the East, both because of their destruction of crops and because of their burrows which seriously interfere with farming operations. In addition, they are known to carry the germs of Rocky Mountain spotted fever and other diseases.

Bird migration, W. W. COOKE (*U. S. Dept. Agr. Bul. 185 (1915), pp. 47, pls. 4, figs. 20*).—This is a discussion of the many phases of the subject, including causes of migration, relation of migration to weather, day and night migrants, distance of migration, migration routes (direct and circuitous, eccentric, wide and narrow), slow and rapid migration, casualties during migration, variations in speed of migration, etc. A large number of maps are given which graphically illustrate the data presented.

Entomology, A. W. MORRILL (*Arizona Sta. Rpt. 1914, pp. 359-362*).—In continuation of work against the harvester ant (*Pogonomyrmex barbatus rugosus*) previously noted (*E. S. R.*, 32, p. 549) tests were made of a high pressure pump which volatilizes the carbon bisulphid in an attempt to force the fumes into the insects' underground tunnels, but thus far the results have been unsuccessful. The principal work of the season against this pest consisted in a large scale experiment with London purple, conducted with a view to determining the cost of material and labor and to perfect the methods of this treatment. In the vicinity of Phoenix a 10-acre field, containing 168 nests with bare areas estimated to average 330 sq. ft. each, or a total of approximately 14 acres, was practically cleared of the ants by a series of five applications of this poison, at a total cost per acre of \$1.17.

A considerable quantity of London purple sold by certain druggists in Salt River Valley during the summer of 1913 proved ineffective, and upon analysis by the station chemist was found to contain but 0.35 per cent arsenious oxid (As_2O_3), whereas London purple that was effective contained 27.51 per cent.

The western green June beetle (*Allorhina mutabilis*) is said to be a troublesome pest of nearly all kinds of fruit at the lower elevations in Arizona, peaches, figs, and grapes being the principal crops that suffer. Brief reference is made to investigations of insects that attack the Arizona wild cotton plant (*Thurberia thespesioides*), an account of which by W. D. Pierce of this Department and the author has been previously noted (*E. S. R.*, 30, p. 56).

Fourteenth report of the state entomologist of Connecticut for the year 1914, W. E. BRITTON (*Connecticut State Sta. Rpt. 1914, pt. 3, pp. VIII+113-198, pls. 16, figs. 6*).—The first part of this report consists of a statement of finances and organization; reports of inspection of nurseries, nursery stock, and apiaries; and a discussion of gipsy moth control work and of suppression work with the brown-tail moth.

A summarized account of The Cabbage Root Maggot, by Q. S. Lowry (pp. 142-152), is followed by a report on Field Experiments in Controlling the Cabbage Root Maggot in 1914, by W. E. Britton and Q. S. Lowry (pp. 152-157). The results indicate that tarred paper disks and carbolic acid emulsion are about equally effective in preventing damage from maggots and that sludge (residue from the manufacture of lime-sulphur mixture) is fairly satisfactory. In a discussion of the Outbreak of the Army Worm (pp. 157-173) the author presents a summarized account of the pest with a list of the more important literature relating to it. Experiments in Controlling the White Pine Weevil are described by B. H. Walden (pp. 173-176). The pest continues to do much damage to white pine plantations in the State. Experiments made in controlling the pest by collecting the weevils on pine leaders with a net indicate that at least six collections may be made at an expense not to exceed \$1.50 to \$2 per acre. In work at Portland and Rainbow in which four and five collections were made, respectively, the percentage of injured leaders where the net was used was less than half the percentage of those injured on the checks. Experiments in Controlling a Mite (*Tarsonemus pallidus*) Injuring Snapdragon Plants in the Greenhouse are reported by W. E. Britton, B. H. Walden, and Q. S. Lowry (pp. 176-179). In addition to snapdragon, the leaves of which were badly curled and the entire season's crop threatened as a result of attacks by this mite, chrysanthemum and cyclamen were also injured. The tests indicate that blackleaf 40, used at the rate of one teaspoonful to a gallon of water with the addition of soap and "Fir-tree Oil" (4 to 6 oz. in 2 gal. of water) will control this mite on snapdragon if four applications in the form of a spray are made at intervals of about a week. A Tent Caterpillar Egg Contest (pp. 179, 180), arranged for school children, is briefly described, as is Mosquito Work in Connecticut in 1914 (pp. 181-183). Caterpillars of a noctuid moth (*Hadena turbulenta*) are reported to have attacked wild smilax or "green-briar" (*Smilax rotundifolia*) at Kidds Island, off Stony Creek, Branford. Tests made of a commercial preparation, known as "Corbin," to protect seed corn, show that it reduces the percentage of germination and retards development, where the vitality is not impaired, to such extent that its value is questionable.

The report concludes with a discussion of miscellaneous insect pests, including pink grasshoppers (*Scudderia furcata*), *Polygonia interrogationis* on elm, cherry or pear slug (*Caliroa limacina*), two rare lady beetles (*Harmonia similis* and *Anisocaltria 12-maculata*), the tulip tree scale (*Toumeyella liriiodendri*), the strawberry white fly (*Asterochiton [Alcyrodes] packardi*), the chinch bug, the saddle-back caterpillar, the hickory leaf stem gall louse (*Phylloxera caryacaulis*), injury by bill bugs (*Sphenophorus sculptilis*), the four-lined leaf bug (*Pocilocapsus lineatus*), the grape plume moth, the Colorado potato beetle and zinc arsenite, pupæ of *Macrosargus cuprarius*, the walnut caterpillar (*Datana integerrima*), leaf hopper (*Gypsona flavilincata*) injuring Japanese barberry, controlling green apple aphid, mites on California privet, harlequin cabbage bug in Connecticut, European pine shoot moth (*Evctria buoliana*), the oak pruner (*Elaphidion villosum*), pear psylla, the stalk borer, injury to geraniums by white ants (*Termes flavipes*), false apple red bug in Connecticut (*Lygidea mendax*), and the hickory bark borer (*Scolytus quadrispinosus*).

Report of entomologist, J. R. WATSON (*Florida Sta. Rpt. 1914, pp. XLVI-LVI*).—A brief account is given of entomogenous fungi, studies of which by Rolfs have been previously noted (*E. S. R.*, 30, p. 55), and of the occurrence of white fly fungi in observation groves. Experiments with sprays in the control of the *Anticarsia* caterpillar on velvet beans, commenced in 1912, were

continued during the summer of 1913, and it was found that a mixture of commercial lime-sulphur 1 qt., lead arsenate paste 8 oz., and water 50 gal., may be safely used to control this pest in August and September. Through the use of lime-sulphur in the solution it was possible to double the amount of arsenical previously used without burning the plants, and this mixture satisfactorily controlled the caterpillars. Observations showed that the severity of the damage by the caterpillar was directly proportional to the lateness of the variety. It is stated that if Chinese or other earlier varieties are planted near Florida velvet or other late varieties, the former will largely escape the ravages of *Anticarsia*. By planting Florida velvet beans about the edge of a field in which the main crop is China or other early beans, the caterpillars can be largely concentrated and readily destroyed by spraying with the arsenical.

A brief statement is given of control measures for the bollworm on tomatoes, a more detailed account of which has been previously noted (E. S. R., 32, p. 652). The cottony cushion scale continued to spread with increasing rapidity, the infestation at Key West being a severe one. Miscellaneous insects noted include the sweet potato root borer; *Hemichionaspis minor*, found at the station grounds infesting *Asparagus plumosus*; the chrysomelid beetle *Trirhabda brevicollis*, which was found at Tallahassee damaging pecans; and *Aleyrodes mori* found at Gainesville infesting *Euonymus americanus*.

Insects affecting vegetable crops in Porto Rico, T. H. JONES (*U. S. Dept. Agr. Bul. 192 (1915), pp. 11, pls. 4*).—This article reviews the literature relating to the subject and reports observations made by the author of the more important insect enemies of vegetable crops in Porto Rico.

The control of apple insects in Clinton County, C. R. CROSEY and A. J. MIX (*New York Cornell Sta. Bul. 356 (1915), pp. 115-130, figs. 24*).—This is a brief discussion of the more important insect pests of apples and means of control in Clinton County, including the codling moth, the apple maggot, green fruit worms, plum curculio, eye-spotted bud moth, apple-tree tent caterpillar, forest tent caterpillar, oyster-shell scale, woolly apple aphid, etc.

Insects destructive to grain and grain products stored in bins and granaries, G. A. DEAN (*Kansas Sta. Circ. 47 (1915), pp. 4*).—A popular account.

House fumigation, C. W. WOODWORTH (*California Sta. Circ. 127 (1915), pp. 4, figs. 2*).—A popular account.

How to control the grasshoppers, E. D. BALL (*Utah Sta. Bul. 138 (1915), pp. 79-116, figs. 15*).—A detailed account, particularly as relates to Utah conditions.

Cockroaches, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul. 658 (1915), pp. 15, figs. 5*).—A revision of Circular 51 of the Bureau of Entomology, previously noted (E. S. R., 14, p. 374).

List of the Hemiptera-Heteroptera of Maine, H. M. PARSLEY (*Psyche, 21 (1914), pp. 139-149; abs. in Maine Sta. Bul. 234 (1914), p. 294*).—Records of 175 species are included.

The chinch bug, F. M. WEBSTER (*U. S. Dept. Agr., Farmers' Bul. 657 (1915), pp. 28, figs. 9*).—A popular account based upon investigations previously noted (E. S. R., 19, p. 452; 26, pp. 347, 454).

Spraying for the grape leaf-hopper, H. J. QUAYLE (*California Sta. Circ. 126 (1915), pp. 6, figs. 2*).—This circular gives directions for spray work against the grape leaf hopper, a detailed account of which pest has been previously noted (E. S. R., 20, p. 557).

The woolly white fly (*Aleurothrixus* [*Aleyrodes*] *howardi*), J. R. WATSON (*Florida Sta. Bul. 126 (1915), pp. 79-102, figs. 12*).—A summarized account of the woolly white fly, studies of which by Back (E. S. R., 23, p. 257) and others have been previously noted.

The author states that the pest is rapidly spreading and will soon be found over all the citrus section of Florida. While it usually does little damage, it is capable of causing an almost total loss of the year's crop and is a severe check to growth. "Unless preventive measures are taken, a severe attack will be followed by a marked rise in the amount of purple scale, which will inflict equal or greater damage. The miscible oils are effective against the early stages of the larvæ of the woolly white fly. Both the red and brown fungi have been found growing sparingly on the woolly white fly. A species of *Cladosporium* probably sometimes kills up to 80 per cent. The woolly white fly is heavily parasitized by a minute hymenopteron, which sooner or later controls an outbreak. Because of this it probably will never develop into as permanently serious a pest as is the common citrus white fly. The parasite apparently does not control the late winter brood."

Recent Illinois work on the corn-root aphid and the control of its injuries, S. A. FORBES (*Illinois Sta. Bul.* 178 (1915), pp. 405-466, figs. 18).—This bulletin reports the results of work with the corn-root aphid carried on from 1907 to 1910 in continuation of that of 1905 and 1906 (E. S. R., 21, p. 57). A circular relating to this work has been noted (E. S. R., 28, p. 855).

"The principal measures of protection against the corn-root aphid are rotation of crops; an early and deep plowing, followed by the repeated deep disking, of corn ground heavily infested by ants or known to have borne a crop injured by the root aphid; and the use of repellent substances at planting time, not by direct application to the seed (which is dangerous to germination and early growth) but by previous mixture with chemical fertilizers or other powdered substances, to be dropped with the seed by means of a fertilizer dropper attached to the corn planter. . . .

"Experiments of 1907 show that wet weather at planting time may either result in serious injury to the seed if repellents have been applied to it direct, or in such washing away of the repellent substances that they produce no effect, either on the seed or on the ants and aphids, the character of the effect apparently depending on the amount of rainfall and on its relation to the time of actual planting. Comparative experiments show that the injurious effects reported were not due, as at first surmised, to differences in the quality of the repellents used in different operations. Laboratory experiments with a considerable variety of repellents applied by uniform methods to colonies of the cornfield ant in a special cage showed that oil of tansy, oil of lemon, anise oil, tincture of asafetida, apterite, and vermicide were very strongly repellent; that kerosene, camphor, and coal tar were less effective repellents; and that a considerable number of other substances tested were, if repellent at all, too slightly so to make them practically useful.

"Additional field experiments made in 1908, in a spring season which proved to be very wet, resulted in no injury to the seed, and on the other hand in no benefit to the crop, flooding rains apparently washing away the repellents before they could take effect upon either the seed corn or the insects.

"Experiments made in 1910 with tincture of asafetida and oil of lemon, applied first to bone meal which was then dropped with the corn by means of a fertilizer dropper attachment to the planter and tested by the yield at corn husking, showed a gain of 5.6 bu. per acre by the use of asafetida and 10.8 bu. per acre by the use of oil of tansy, the first gain being obtained at a cost for materials and additional labor of 34 cts. a bushel, and the second gain at 27 cts. a bushel. This result was the more encouraging since a very unfavorable spring caused an unusually poor stand and reduced greatly the general yield of corn. In a good corn season the gain would have been greater for the same cost.

"Additional experiments with deep plowing and repeated disking made in 1909 showed in one case a decrease, due to the treatment, of 43 per cent in the number of hills infested by ants and 18 per cent in the number of ants in the infested hills, and a decrease of 27 per cent in the number of hills infested by root lice and of 9 per cent in the number of the root lice themselves. In another case the number of hills infested by ants was reduced 71 per cent and the number of ants in the infested hills 83 per cent, the number of hills infested by root lice 86 per cent and the number of root lice in the infested hills 61 per cent. The same experiment showed that deep disking with a 20-in. disk was much more effective in diminishing the number of ants and root lice than was the comparatively shallow disking of a 16-in. disk, the difference between the two methods of treatment being 34 per cent and 48 per cent in the number of hills infested by ants and aphids, respectively, and 13 per cent and 35 per cent in the number of these insects themselves. It was incidentally shown by this experiment that plowing to a depth of 4 in. does not sufficiently break up the nests of the ants, but that about 85 per cent of them may be broken up by plowing 6 in. deep, the remainder being at least broken into.

"Observations made at night upon the movements of colonies of ants out of plats treated as above, and across furrows surrounding them, showed nearly two and a half times as many migrations from the plats deeply stirred as from the check plat. Migration lines across furrows plowed through the center of each of the plats a week after planting showed the amount of normal underground movements of the ants at this time. Making due allowance for this, it appears that the migration movement caused by the disturbance of the ants in treated plats was more than five times as great as is normal.

"Plowing to a depth of 6 in. in a Galesburg field in 1910 dispersed 55 per cent of the ant colonies in this field, and one disking after plowing dispersed 15 per cent more. Plowing 6 in. deep, disking three times, and rolling once increased the yield of the plat nearly 25 per cent, at a cost of 22 cts. a bushel. One 20 in. disking followed by rolling gave all the advantages obtainable by additional diskings. Fall plowing and one spring disking are much more effective than spring plowing with no disking, the latter containing about three times as many ants and four times as many aphids as the former.

"Change of corn ground to oats for one year and fall plowing of the oats stubble gave a larger yield by 25 per cent than adjacent ground kept continuously in corn, this difference being accompanied by a root louse infestation of young corn on the oats stubble about one-tenth that found in corn on old corn ground."

The gipsy moth, W. E. BRITTON (*Connecticut State Sta. Bul. 186 (1915), pp. 24, figs. 16*).—A summarized account of this pest, particularly as relates to Connecticut.

Studies of the codling moth in the central Appalachian region, F. E. BROOKS and E. B. BLAKESLEE (*U. S. Dept. Agr. Bul. 189 (1915), pp. 49, pl. 1, figs. 23*).—This is a report of studies of the codling moth, commenced in the spring of 1911 and continued for three successive years, which form part of the investigations of this insect that have been carried on by the Bureau of Entomology throughout the United States, including Arkansas (*E. S. R., 21, p. 455*), Pennsylvania (*24, p. 256*), California (*25, p. 154; 28, p. 558*), Michigan (*28, p. 60*), and New Mexico (*31, p. 252*). The work was conducted at several points in Virginia, West Virginia, and Maryland, comprising a difference in latitude of 1° 40' and in altitude of about 3,100 ft., the most southerly and least elevated station being at Charlottesville, Va., the most northerly at Hagerstown, Md., and the most elevated at Pickens, West Va.

In this work particular attention was given to the time of appearance of the different broods at various altitudes and latitudes. The work was conducted by selecting for banding from 10 to 15 unsprayed bearing apple trees of the late-ripening varieties in each of the several localities in the States above mentioned. Bands applied to the trees in the spring before the first brood larvæ commenced to leave the fruit were removed and examined at intervals of a week or 10 days and the larvæ taken from them, counted, and placed in rearing jars and records kept of their transformation. During the course of the work more than 20,000 larvæ were collected and placed in jars for rearing, examinations being made every week or 10 days. Much of the data relating to these investigations are presented in tabular and diagrammatic form.

During a single year the codling moth in the region covered by the present studies produces one full brood of larvæ and a partial second brood, the size of the second brood depending more or less on the latitude and altitude of the locality. There seems, however, to be no constant rate of difference between the earlier and later localities, due largely to the responsiveness of the species during its metamorphic changes to local and transient weather conditions.

"During the time of the investigations the first brood larvæ began entering the fruit at Charlottesville from April 28 to May 15, and second-brood larvæ from June 25 to July 1. At Pickens first-brood larvæ began entering the fruit from June 20 to July 1, and second-brood larvæ about August 10. Between these two localities there is a greater difference in the time of the regular periodical changes of the insect that occur late in the season than of those that occur early in the season. This is probably due to the cumulative retarding effect of the more frequent unfavorable weather conditions at the higher point. . . . Records of the numbers of larvæ collected from trees on which bands were placed around the trunks and also around the bases of the larger branches indicate that 41.49 per cent drop to the ground and then ascend the trunk to pupate and 58.51 per cent crawl down the branches from the infested fruit to pupate. . . .

"Two specimens of ants (*Solenopsis molesta* and *Lasius niger americana*) were found in several localities devouring codling-moth larvæ. Larvæ and adults of the beetle *Tenebroides corticalis* were found frequently feeding on codling-moth larvæ and pupæ. Six species of hymenopterous and one of dipterous parasites were reared in the jars. Of these the most destructive to the codling moth were *Ascogaster carpocapsa* and *Itoplectis marginatus*. Hair-worm parasites (*Mermis* sp.) were abundant in one locality and very materially reduced the number of wintering larvæ in the year 1911."

The spring cankerworm situation in Kansas, G. A. DEAN (*Kansas Sta. Circ.* 46 (1915), pp. 7, figs. 7).—This circular describes methods of control for the spring cankerworm, the ravages of which in Kansas have extended over a period of several years. This pest is said to have killed more apple trees in Kansas in a single season than the San José scale has killed during its entire history as a pest in the State.

The true clothes moths, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul.* 659 (1915), pp. 8, figs. 3).—A reprint, with slight revision, of Circular 36 of the Bureau of Entomology, previously noted (*E. S. R.*, 10, p. 655).

The root maggot pest, E. B. STOOKEY (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 12, pp. 2-8, figs. 6).—The damage caused by the root maggot is said to have been so great in the State of Washington during the past few years that many growers have almost given up growing radishes, cabbages, and like plants. A brief report of treatments in the experimental control of the pest is given, the results of which agree in general with those

obtained at other stations. The report of work prior to 1913 has been previously noted (E. S. R., 28, p. 555).

Work with stomach and contact poisons in combating the maggot after it has started working on the plant gave negative results. As a result of work with repellants the only remedy recommended for transplanted plants is the use of 3-inch tarred felt disks.

The huisache girdler (*Oncideres putator*), M. M. HIGH (U. S. Dept. Agr. Bul. 184 (1915), pp. 9, pls. 4).—The huisache tree (*Acacia farnesiana*), used as a shade and hedge tree in the Southwest, has a number of insect enemies, of which the girdler (*O. putator*) is the most injurious. This insect often damages the young trees through completely severing them a few inches above ground. The species first came under the author's observation in the lower Rio Grande Valley during the summer of 1910. It is said to saw with ease branches 1½ in. in diameter, as many as 63 girdled branches of one tree having been observed by the author.

The species has been recorded from Arizona, New Mexico, and Texas, and from Mexico. In addition to huisache, it has been found feeding and ovipositing upon mesquite (*Prosopis glandulosa*), huajilla (*Acacia berlandieri*), ratama (*Parkinsonia aculeata*), and *Mimosa lindheimeri*. The adults begin to appear early in September and continue to emerge until the latter part of November. No statement is made as to the incubation period of the egg. The duration of the larval period is said to be approximately 42 weeks under ordinary conditions. No pupæ were observed until August, the first adult beetle observed emerging September 15. The duration of the pupal stage is approximately four weeks with an average mean temperature of 72.5° F. There is only one generation of this beetle each year, approximately 12 months being required for the life cycle from egg to adult.

Several parasitic enemies of the egg and larva were reared, including *Chryseida inopinota*, *Eurytoma* sp., *Cynophanes* sp., a pteromalid, and *Meteorus* sp. Since this insect spends at least 10 months in the severed branches, it may be controlled by collecting and burning the pruned branches.

The spotted click beetle (*Monocrepidius vespertinus*), H. C. EAGERTON (South Carolina Sta. Bul. 179 (1914), pp. 3-8, pls. 2).—During the course of studies of the corn and cotton wireworm (*Horistonotus uhlerii*), a brief reference to which has been previously noted (E. S. R., 30, p. 545), it was found associated with the spotted click beetle, here dealt with, which the author estimates is responsible for 45 per cent of the damage formerly attributed to *H. uhlerii*.

The larvæ of the spotted click beetle apparently prefer cotton seed and young cotton roots to seed or young roots of corn, but in the absence of cotton they attack corn, often doing serious damage. Unlike the larvæ of *H. uhlerii*, those of *M. vespertinus* seem to be abundant on almost any type of soil, occurring on light sands and heavy silt soils, although the greater injury occurs generally on sandy upland.

In a study of its life history the author found from 9 to 10 days to be required for the eggs to hatch during July and about 20 days for eggs deposited September 8. As with *H. uhlerii*, oviposition appears to take place in the evening or night. The eggs are not deposited more than 1 in. beneath the surface of the soil. During the winter of 1913-14 the larvæ were found about 3 to 3.5 in. below the surface and were never found deeper except during dry weather in the spring of 1914, when they occurred 5 to 6 in. below the surface. Their food appears to consist mainly of decaying vegetable matter and ground larvæ, but when these are not abundant they do not hesitate to attack the

roots or planted seed of corn, cotton, and other plants. During June and July the pupal stage, which is found from 3 to 5 in. below the surface, is said to last from 10 to 12 days. The life cycle of a specimen reared from an egg deposited July 28, 1913, required 330 days—12 for the egg, 305 for the larva, and 13 for the pupa. To this may be added 10 days from emergence to oviposition, which represents the maximum period.

A night hawk, probably *Chordciles virginianus*, is said to feed upon the adult beetles. Since the larva seldom burrows deeper than 4 in., fall and winter plowing are recommended as an aid in its control. In a rotation of cotton, corn, and oats, the oat stubble should be left undisturbed after harvest until September 15, as the adults do not frequent such fields for egg laying. Where the species is injurious to tobacco, it is recommended that a handful of cotton seed be placed halfway between plants to attract the wireworms away from the young plants until the young tobacco is sufficiently strong to withstand the attack.

FOODS—HUMAN NUTRITION.

Acidity in wheat flour, L. A. FITZ (*Oper. Miller*, 20 (1915), No. 1, pp. 36-38).—Analyses made by J. W. Calvin and Leila Dunton at the Kansas Experiment Station are reported. Judging by the results with different millings of the same grain, high acidity is apparently an unreliable test for unsoundness in flour. The acidity is in part at least attributed to phosphates and amino acids normally occurring in flour.

Accidental poisoning due to flour containing barium carbonate, L. HUGOENENQ (*Ann. Falsif.*, 7 (1914), No. 63, pp. 54-56).—Several cases of poisoning are reported in which the cause was stated to be flour which contained barium carbonate.

Feterita, J. C. SUMMERS (*Oper. Miller*, 20 (1915), No. 1, pp. 42-44, figs. 4).—Some baking tests are reported which were made upon doughs prepared with feterita flour alone; a mixture of feterita flour and soft wheat flour 1:1; feterita flour and hard spring wheat flour 1:1; soft wheat flour alone; and hard spring wheat flour alone.

It is stated that the feterita flour is soft and breaks up badly in scouring and milling. The flour is of a dark red color and contains no gluten, which accounts for the poor volume of the loaves made from it. The bread made from feterita flour alone was heavy and had a poor texture and color. The bread made from feterita and wheat was somewhat better in quality, but also somewhat heavy and poor in texture. Pancakes and gems made from feterita flour alone were heavy and had a flat taste, while those made from the feterita flour and wheat flour were of good quality and had only a slightly flat taste, which was easily overcome by the use of sirup and spices.

Some data on peanut butter, C. A. A. UTT (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 9, pp. 746, 747).—Chemical and microscopical examinations were made of a number of samples to determine whether oils other than peanut oil were incorporated in the product. In the samples examined no foreign starch or oil was detected.

[The utilization of prickly pears as human food]. **Report of the Prickly-pear Traveling Commission**, 1st November, 1912-30th April, 1914, T. H. JOHNSTON and H. TRYON (*Brisbane: Govt.*, 1914, pp. XX+131, figs. 66).—Information is given regarding the use of the fresh ripe fruit of the prickly pear as food in South Africa, the Mediterranean regions, Central and South America, and Mexico. To a slight extent it is also used in the United States as food. In countries where this fruit forms an important part of the food

supply it is either dried, converted into preserves, or, as is sometimes the case, used in making jams, jellies, alcohol, vinegar, molasses, or sugar. Analyses of the dried leaves of different varieties indicate a fuel value of between 1,400 and 1,500 calories per pound.

Data pertaining to its use in stock feeding are noted on page 70.

Mushrooms and other common fungi, FLORA W. PATTERSON and VERA K. CHARLES (*U. S. Dept. Agr. Bul. 175 (1915), pp. 64, pls. 38, fig. 1*).—This bulletin is intended to furnish the amateur with means for identifying some of the more common species of mushrooms and for distinguishing between poisonous and edible varieties. The general morphological structure of mushrooms and other fungi is discussed, and botanical descriptions are given of selected species from each of the most familiar genera, with special reference to the distinctive features. These are also illustrated by a number of photographic reproductions. The bulletin contains a few tested recipes for cooking mushrooms and a list of reference books is appended.

Analyses of human milk, O. SPINDLER (*Apoth. Ztg., 29 (1914), No. 16, pp. 235-240*).—Results of analyses are given from which it is concluded that human milk, unlike normal cows' milk, contains a large amount of catalases and that no definite relation exists between the density of the serum, total solids, and fatty matter. The catalases are found partly dissolved in the serum and partly occluded in the fat globules, and are thought to play an important part in the nutrition of infants.

Mother's milk of the first period of lactation and the influence of calcium and phosphorus additions on its composition, F. ZUCKMAYER (*Pflüger's Arch. Physiol., 158 (1914), No. 3-5, pp. 209-218; abs. in Chem. Zentbl., 1914, II, No. 5, p. 415*).—An examination of mothers' milk during the first 10 days of the lactation period showed in 26 cases large variations in the calcium and phosphorus content, and these variations still existed after the addition of calcium and phosphorus compounds to the diet of the mother. The use of these compounds during the advanced stages of pregnancy produced a normal milk, but the calcium content increased from 10 to 72 per cent, and the values for phosphorus pentoxid, nitrogen, and ash were also greater.

What every ice cream dealer should know (*Schenectady, N. Y.: Daly Bros. Manufacturing Corporation, 1914, pp. 228, pls. 17, figs. 4*).—This is a general treatise on ice cream manufacture, intended for the use of the ice cream trade. A number of suggestions are given, together with standard recipes, and considerable information regarding the sanitation of ice cream factories, the proper selection and storage of raw materials, and the handling of the finished product. A number of modern ice cream plants located in various parts of the country are described. One section of the book is devoted to soda fountain hints. This also contains a number of recipes and suggestions to proprietors of soda fountains.

The preparation of pure sucrose and dextrose caramels, G. D. BEAL and H. F. ZOLLER (*Jour. Amer. Pharm. Assoc., 3 (1914), No. 4, pp. 495-497*).—From the results of these experiments the authors draw the following conclusions:

"Caramel is best prepared by heating cane sugar or glucose at 210° for 30 minutes. A somewhat higher yield is obtained by longer heating, but some insoluble matter is formed at the same time. The best method of purification is found to be dialysis in a collodion membrane."

Harmful effect of certain sugar cane products, R. BLOSSER (*Jour. Amer. Med. Assoc., 63 (1914), No. 6, pp. 481, 482, fig. 1*).—A preliminary report of experiments with laboratory animals (dogs) carried out to determine whether or not the use of cane sugar is deleterious. The effect of ingestion of large

amounts of cane sugar was considered negative, but it is stated that general disturbances and abnormal development were produced by the continued consumption of a cheap grade of sirup.

Lime juice, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 295 (1914), pp. 17*).—In the examination of 30 samples of lime juice purchased throughout Canada only 5 were found to meet the requirements of the departmental standards.

Leavening agents, R. N. HART (*Easton, Pa.: The Chemical Publishing Co., 1914, pp. 90+[3], figs. 13*).—This book is intended to give the baker a knowledge of the principles of fermentation as applied to baking, and deals with yeasts, leavening agents, salt-rising fermentation, baking powders, aerated bread, and milk powder. The nature and characteristics of yeasts, together with their selection, keeping, and tests, are considered somewhat at length. The manufacture of compressed yeast is described and the chemistry of yeast fermentation is discussed. The chemical properties and the use of baking powders are also considered, together with their manufacture.

The blanching of canned goods, R. BERG (*Ztschr. Angew. Chem., 27 (1914), No. 20, Aufsatzteil, pp. 148-152*).—The large amount of analytical data reported shows that a very considerable loss of organic matter and mineral constituents occurs when meat, fish, and especially vegetables, are boiled preliminary to canning, particularly if the blanching water is thrown away. The author concludes that a more nutritious and tasteful product can be obtained without the preliminary blanching.

Packing tea in foil containing lead, BORDAS (*Ann. Falsif., 6 (1913), No. 60, pp. 566-569*).—Although analyses of a number of samples of the foils used for this purpose showed them to consist of over 90 per cent of lead, the opinion is given that the tea is sufficiently dried in the curing process to preclude any danger of plumbic solvency.

The toxicity of caffeine, K. BRAUER (*Ztschr. Öffentl. Chem., 20 (1914), No. 14, pp. 270, 271; abs. in Chem. Zentbl., 1914, II, No. 12, pp. 797, 798*).—The author is of the opinion that the toxicity of coffee is influenced both by the time of roasting and the chemical nature of the caffeine compounds.

Preservatives and other chemicals in foods: Their use and abuse, O. FOLIN (*Cambridge [Mass.]: Harvard University Press, 1914, pp. 60*).—A critical summary and digest of the general question of the use of preservatives in foods. A number of suggestions are made as to work which, in the opinion of the author, is needed to settle this important question.

[Analyses of foods, drugs, and beverages], R. F. KOLB (*Ala. Dept. Agr. Bul. 61 (1914), pp. 65-85*).—Definitions and general and analytical data are given regarding a number of miscellaneous foods, drugs, and beverages.

Special food and drug analyses, 1914, R. E. ROSE and L. HEIMBURGER (*Ann. Rpt. State Chem. Fla., 1914, pp. 138-167*).—Tabulated data are presented regarding analyses of 146 samples of miscellaneous foods, beverages, and drugs.

Thirteenth annual report of the state food commissioner of Illinois, A. F. JONES (*Ann. Rpt. State Food Comr. Ill., 13 (1912), pp. 454, figs. 12*).—The work carried on under the state food law during the year 1912 is reviewed and information given upon a number of pure food topics. In the report of T. J. Bryan, state analyst, the results are given of the examination of 6,523 samples of various foods and food products of which 2,091 were found to be illegal. The reports of the state bacteriologist and of the district food and stock food inspectors are given, also records of prosecutions brought under the state food law, court decisions, the texts of 24 bulletins issued by the commission, tentative food standards adopted by the commissioner, rules for labeling, and the texts of several food, stock feeding, and cold storage laws.

Fourteenth annual report of the state food commissioner of Illinois, W. S. MATTHEWS (*Ann. Rpt. State Food Comr. Ill., 14 (1913), pp. 135, figs. 2*).—The work carried out by the commissioner under the state food laws during the year 1913 is briefly reviewed, and the report of J. C. Johnstone, state analyst, gives the results of the examination of 6,038 samples of miscellaneous foods, of which 2,034 were found to be illegal, and extended tabulated data regarding these samples. The text of standards adopted by the state food standard commission are given, the legal work of the commission is reviewed, and the text of three bulletins issued by the department is given.

[**Food and drug inspection and analysis**], W. F. COGSWELL ET AL. (*Bien. Rpt. Bd. Health Mont., 7 (1913-14), pp. 79-170*).—The work of the department during the years 1913 and 1914 is reviewed. This includes the inspection of dairies, hotels and restaurants, meat markets, slaughterhouses, bakeries, etc., as well as analyses of 433 samples of miscellaneous food products, and the reports of the inspectors.

[**Food analyses and pure food topics**], J. FOURR (*Penn. Dept. Agr., Mo. Bul. Dairy and Food Dir., 12 (1914), No. 10-11, pp. 135*).—Information upon a number of miscellaneous pure food topics and the results of the examination of a large number of samples of dairy and food products are given.

Sixth annual report of the food and drug commissioners, F. A. JACKSON, F. W. COOK, and F. N. STRICKLAND (*Ann. Rpt. Bd. Food and Drug Comrs. R. I., 6 (1914), pp. 21*).—A review and summary of the work carried out during the year ended December 31, 1914, is given, which includes general information regarding a number of pure food and drug topics.

Fourteenth annual report of the food and drug commissioner of South Dakota, G. G. FRARY (*Ann. Rpt. Food and Drug Comr. S. Dak., 14 (1914), pp. 351*).—The work of the department as carried out covers the inspection and analysis of foods, drugs, beverages, paints, and feeding stuffs, and the inspection of hotels and public buildings. In addition to the financial statements, extended data regarding the analyses and inspections made are reported. In part of the report are reproduced a number of the bimonthly bulletins of the department which contain information upon a number of miscellaneous food and drug topics.

[**Pure food topics and food and drug inspection**], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul. 3 (1915), No. 16, pp. 265-288*).—This bulletin presents the results of the inspection of 678 grocery stores, the score of each place inspected being given. A list of beverages registered for the year 1915 and information regarding several proprietary medicines examined conclude the publication.

Department rulings relative to food and dairy products and their labeling ([*Columbus*]: *The F. J. Heer Printing Co., 1914, 1. ed., pp. 30*).—The text is given of the rulings of the Ohio Agricultural Commission.

The food inspector's handbook, F. VACHER (*New York: D. Van Nostrand Co., 1913, 6. ed., rev. and enl., pp. 311, pls. 19, figs. 77*).—This is the sixth edition of a publication previously reviewed (E. S. R., 17, p. 576). It is stated that the publication has been greatly revised and enlarged and the number of illustrations increased.

The commercial aspect of electric cooking and heating, T. P. WILMSHURST (*Jour. Inst. Elect. Engin. [London], 51 (1913), No. 220, pp. 180-201, pl. 1, figs. 6*).—Electric cooking and heating are considered in detail and data are given to show the increased efficiency of electric over coal- or gas-fired ovens. The loss in weight of different kinds of meat was apparently less with electric cooking and the flavor of the product claimed to be vastly superior.

A specially shaped kettle for heating water is described in which it is stated that 3 pt. of water can be boiled in six minutes with an efficiency of over 98 per cent. Other pieces of electrical apparatus are described which tend to show the economy of electric cooking.

The questions of heating water and house heating are also taken up to some extent. The paper is followed by a discussion.

Electric cooking on a large scale, W. SCHULZ (*Elektrotech. Ztschr.*, 34 (1913), No. 29, pp. 821-825, figs. 13).—Two large electric kitchens, each capable of providing food for 200 to 300 people, are described in detail. Efficiency experiments were conducted in one of these from which it was determined that the energy consumption per meal ($\frac{1}{2}$ pt. soup, $6\frac{1}{4}$ oz. meat, $5\frac{1}{2}$ oz. potatoes, $2\frac{1}{2}$ oz. other vegetables, 0.075 pt. milk, and 0.42 pt. coffee) averaged 0.394 kilowatt hour.

In addition to the large electrically heated ovens, it is a noticeable feature that the saucepans or boilers are one-piece nickel-plated utensils provided with bottom and also side heating elements. The heating elements are inclosed in an outer nickel-plated shell provided with an air valve to prevent excessive pressure.

The usefulness of nickel cooking utensils, V. GHEORGHIU (*Ber. Deut. Pharm. Gesell.*, 24 (1914), No. 6, pp. 303-308; *abs. in Chem. Zentbl.*, 1914, II, No. 15, p. 945).—Pickled cucumbers and beef, after boiling two hours in a nickel dish, gave on analysis the following amounts of nickel: Pickles, 107.4 mg.; liquid from pickles, 135.6 mg.; and cooked beef no nickel per package of the original weight of foods.

Kitchen ventilation for a modern hotel (*Heating and Ventilating Mag.*, 12 (1915), No. 1, pp. 13-18, figs. 5).—A detailed description of the ventilating system of a modern hotel, with special reference to the kitchen, is given.

Dollar luncheons to serve four people (*Springfield, Mass.: The F. A. Bassette Co.*, 1914, pp. 34).—A menu appropriate to each month of the year, together with recipes and cost data, is given. It is stated that these luncheons can be served for 25 cts. per person or less, under some conditions.

Feeding of Arab soldiers, J. AMAR (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 24, pp. 811-814).—Information is given regarding the rations of the soldiers. The relationship between food and muscular activity with reference to troops is also discussed.

Studies of the protein minimum, M. HINDHEDE (*Skand. Arch. Physiol.*, 30 (1913), No. 1-3, pp. 97-182, figs. 4).—In this paper a summary and digest of the literature regarding the protein requirement of the body is given and the author reports the results of a large number of metabolism experiments. From these results and those of observations made upon members of his own family who received a low protein diet for several years he concludes that the need of protein increases almost directly with the energy consumption. He recommends a low-protein diet.

Studies of unbalanced diets, P. TACHAU (*Biochem. Ztschr.*, 65 (1914), No. 3-4, pp. 253-272, figs. 4; *abs. in Zentbl. Biochem. u. Biophys.*, 17 (1914), No. 13, pp. 479-480).—The results are reported of experiments in which laboratory animals (mice) were maintained for some time upon an exclusive diet of rye bread, during which period their weight curves showed only slight variations. The addition of fats and carbohydrates to the diet in such amounts as to give an unbalanced ration resulted in a decline in the weight and general nutritive condition of the animals. Similar results were obtained by feeding an excessive amount of inorganic salts.

The influence of restricted rations on growth, E. B. HART and E. V. McCOLLUM (*Jour. Biol. Chem.*, 17 (1914), No. 2, Proc., pp. XLIV, XLV).—Feeding experiments with laboratory animals (rats and swine) have shown that a ration limited to the wheat kernel and distilled water is insufficient to maintain growth. Considerable growth was obtained when a salt mixture consisting of potassium phosphate, potassium citrate, and calcium lactate was added to the wheat ration, though after a time growth ceased and the animals began to lose weight. These results seem to harmonize with the theory that the wheat kernel contains a toxic substance the injurious character of which is greatly diminished during the germinating process, and that failure to grow is not due entirely to the incomplete nature of the wheat protein.

Constancy of the content of phosphorus lipoids in the total organism—lipoid content during growth, A. MAYER and G. SCHAEFFER (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 1, pp. 102–105; *abs. in Chem. Zentbl.*, 1914, II, No. 17, p. 1058).—Experiments with a large number of warm- and cold-blooded animals indicate that the lipoid phosphorus content for organism of the same species is very constant, and that both lipoid phosphorus and cholesterol vary but little during growth.

Constancy of the content of fatty acids and cholesterol in the total organism.—Estimation of fatty reserves, E. F. TERROINE (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 1, pp. 105–108; *abs. in Chem. Zentbl.*, 1914, II, No. 17, p. 1058).—Analytical data show that the fatty acid content of normal animals is variable while that of animals of the same species dead of starvation is very constant. The difference between these two values is the fatty acid reserve. The amount of cholesterol contained per kilogram of body weight of starving animals is also constant.

Fat intoxication, O. WELTMANN (*Wiener Klin. Wchnschr.*, 27 (1914), No. 27, p. 971; *abs. in Zentbl. Physiol.*, 29 (1914), No. 1, p. 42).—Continued experimental feeding of fats produced hemolysis and the presence of a lipidlike substance in the blood. As this did not occur with the incorporation of fatty acids, such as from 1 to 2 gm. of oleic acid, it is concluded that the mechanical digestion of fats in the intestinal tract produces hemolytically active end products which under certain conditions, such as injury to the intestinal membrane, may pass into the blood.

Observations on creatin and creatinin, P. A. SHAFFER (*Jour. Biol. Chem.*, 18 (1914), No. 3, pp. 525–540).—From a large number of analyses of muscle, the results of which are here reported, the author draws the general conclusion that the creatinin of the urine is derived from the creatin of the muscles.

The effect of salts and other ions upon oxidative processes in the body.—I, Introductory statements, N. ZUNTZ (*Ztschr. Balneol., Klimat. u. Kurort Hyg.*, 6 (1913), No. 12, pp. 333–336).—The work of other investigators having shown that the salt content of water very decidedly influences the oxidative processes in the embryo cell qualitatively and quantitatively with respect to the respiratory quotient and the oxygen consumption, experiments were undertaken by the author and his associates to determine whether a similar influence on cell life of higher organisms could be brought about by concentration and mixing of ions in the cell contents.

The experimental data accumulated made it clear, according to the author, that the increased respiratory quotient observed is not due to the increased work of digestion but to the direct metabolic effect of the circulating salts.

Experimental studies of the effect of salts upon respiratory metabolism, II, W. MÄDER (*Ztschr. Balneol., Klimat. u. Kurort Hyg.*, 6 (1913), No. 13, pp. 363–375).—The problem studied was to determine whether or not certain

changes in the mineral content of the body and the food would bring about changes in the normal relation of the oxidative processes of carbohydrates and fat.

Experiments which were made with a dog weighing 18 kg. and extending over 6 months showed that while there were variations in the different tests they were neither large nor uniform enough to predicate a specific effect on the combustion processes in the animal body and the extent of such processes ascribable to the specific action of one or the other of the metal ions under consideration. In the different periods, sodium chlorid, meat ash, potassium chlorid, calcium chlorid, and magnesium chlorid, were given and the respiratory quotient studied.

The details are reported in full.

On the average composition of the alveolar air and its variations during the respiratory cycle, A. KROGH and J. LINDHARD (*Jour. Physiol.*, 47 (1914), No. 6, pp. 431-445, figs. 7).—A new method is described for determining the average composition and the variations in composition of alveolar air taking place during an expiration. A discussion of the accuracy of the method in its practical application is included.

Respiratory exchange in dry and humid atmospheres with and without ventilation, E. SOCOR (*Compt. Rend. Soc. Biol. [Paris]*, 76 (1914), No. 19, pp. 873-875; *abs. in Zentrbl. Biochem. u. Biophys.*, 17 (1914), No. 11-12, p. 415).—Metabolism experiments with tubercular laboratory animals (guinea pigs) showed a decreased output of carbon dioxide when the animals were maintained in a warm, humid, unventilated atmosphere. Ventilation increased the carbon dioxide production.

ANIMAL PRODUCTION.

Utilization [of prickly pear] as fodder for stock, T. H. JOHNSTON and H. TRYON (*Rpt. Prickly Pear Travel. Com., Queensland, 1912-1914*, pp. 35-37, 52, 53, 89, 113, pl. 1).—A review of the work of experiment stations in South Africa, southern Europe, Mexico, and Australia on the feeding value of prickly pear.

It appears that cattle, horses, goats, hogs, and ostriches can be maintained on a ration of pear and can thrive on it if supplemented by grain or alfalfa. It is said that unless care be exercised, purging of animals frequently occurs. Also the small spines from the fruit penetrate the tongue and jaws and give rise to inflammation, which may extend even to the stomach and cause death. It is stated that the attempt to ensile prickly pear has not been satisfactory, although it is thought better results could be obtained if the fruit was mixed with alfalfa, hay, or oat chaff.

Analyses are given for both the fresh and the dried fruit of six different varieties of the pear.

Chemical composition of weeds as feed and fertilizer material, M. KLING (*Landw. Vers. Stat.*, 85 (1914), No. 6, pp. 433-470).—Analyses are given of *Convolvulus arvensis*, *Chenopodium album*, *Stellaria media*, *Cirsium arvense*, *Sonchus oleraceus*, and *Mercurialis annua*, together with a brief discussion of their feeding value.

Manufacture of fodder from waste sulphite-cellulose lyes, J. KÖNIG (*French Patent 469,768, March 19, 1914*; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 1, p. 47).—"Waste sulphite lye is mixed with the residual liquid obtained in the treatment of wood with dilute alkalis and acids, with the aid of heat and pressure, and the mixture is evaporated, neutralized, and freed from sulphurous acid; the product can be used as a cattle feed. The sulphite lyes may be submitted to a preliminary treatment with acid or alkali, which enables

them, after neutralization and separation of sulphurous acid, to be evaporated separately; this product also can be used as a feed by itself. The residual liquid obtained from the acid and alkali treatment of cellulose may be treated for the extraction of resins, tannin, sugar, etc., before being mixed with the sulphite liquor."

Commercial feeding stuffs, B. B. ROSS (*Ala. Dept. Agr. Bul. 61 (1914)*), pp. 5-61).—Analyses are reported of cotton-seed meal, shorts, bran, screenings, molasses feed, middlings, ship stuff, dried-beet pulp, alfalfa meal, and various mixed and proprietary feeds. There is included the text of the state feeding-stuffs law and definitions for the various feeding stuffs.

Commercial feeding stuffs, J. P. STREET ET AL. (*Connecticut State Sta. Rpt. 1914, pt. 4, pp. 199-226*).—Analyses are given of the following feeding stuffs: Cotton-seed meal, linseed meal, bran, middlings, corn gluten feed, corn gluten meal, hominy feed, corn, corn meal, buckwheat middlings, malt sprouts, dried brewers' and distillers' grains, dried-beet pulp, molasses feed, fish scrap, shredded alfalfa, cacao shells, soy beans, soy-bean fodder, silage corn, and various mixed and proprietary feeds.

The breeding and improvement of domestic animals, P. DIFFLOTH (*Zootechnie Spéciale. Élevage et Exploitation des Animaux Domestiques. Paris: J. B. Baillière & Sons, 1914, 3. ed., pp. 610, figs. 183*).—This volume, which is one of the series entitled *Encyclopédie Agricole*, is a general treatise on the breeding, feeding, care, and management of cattle, sheep, goats, swine, and horses.

The Argentine live-stock industry in the principal production centers, PFANNENSCHMIDT (*Ber. Landw. Reichsanst. Innern, No. 33 (1914)*), pp. 164).—A complete statistical review of the live-stock industry in Argentina.

[**Animal production**], E. G. E. SCRIVEN and T. WEEDON (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, pp. 36-39, 148-160, pls. 8*).—A statistical and general review of the live-stock situation in Queensland.

Judging of live stock, J. GINIEIS (*Zootechnie Spéciale. La Connaissance du Bétail. Paris: Libr. Sci. Agr., 1912, pp. XIX+332, figs. 36*).—A general treatise on the desired points of conformation to be sought in judging horses, cattle, sheep, and swine, together with information on the characteristics of the dentition of each and methods of determining age.

The problem of early maturity in breeding from the biological standpoint, R. MÜLLER (*Deut. Landw. Tierzucht, 18 (1914), No. 1, pp. 2-5; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intcl. and Plant Discases, 5 (1914), No. 5, pp. 654-656*).—From the observations of the author and other investigators it appears that early maturity is not entirely dependent upon nutrition, which is its principal determining factor, but is also influenced to a great extent by the activity of the internal secretory glands. While there seems to be no relation between increase in weight or volume of the digestive organs and early maturing, there appears to be a connection between the physiological activity of the digestive organs and early maturity. It appears that the early maturity of the sexual organs and that of the body in general may be independent of each other, for example the combination of high milk yield and early maturity in the same animal seen in the Bates strain of Shorthorns. The effect of early maturity on the length of life of the animal and the period of certain physiological functions has not been fully determined.

Experimental studies in artificial fecundation, A. PIOCCHI (*Indus. Latt. e Zootec., 12 (1914), No. 20, pp. 307-309*).—Successful experiments are reported in which cows were artificially impregnated with from 5 to 14 cc. of sperm from 15 minutes to 8½ hours old and at temperatures varying from 20 to 35° C.

Net energy values of feeding stuffs for cattle, H. P. ARMSBY and J. A. FBIES (*U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 6, pp. 435-491, figs. 2*).—In this paper are reported the results of 76 experiments at the Pennsylvania Institute of Animal Nutrition in cooperation with this Department, using the respiration calorimeter and 9 steers in which the balance of matter and of energy was determined. These experiments were carried out during the years 1902-1912, inclusive, and those to the end of 1907 have been previously reported in full from other sources (*E. S. R.*, 15, p. 799; 17, p. 579; 19, p. 866; 25, p. 872; 28, p. 68; 30, p. 268).

It is said that the losses of feed energy from the animal are of two classes, (1) losses of unused chemical energy in the feces, urine, and methane; and (2) losses in the form of heat due to the increased metabolism consequent upon the ingestion of feed. As to the first class it was found that "the losses of energy in methane and urine were relatively greater on light than on moderately heavy rations. Neither the losses of energy in the feces nor the total losses showed a distinct relation to the amount of feed consumed. Individual differences between animals had no very material influence on the losses of chemical energy. The losses of energy in methane may be computed approximately from the amount of total carbohydrates digested. The metabolizable energy per kilogram of digested organic matter showed but slight variations within the same class of feeding stuffs."

As to the second class it was found that "the heat production is notably greater during standing than during lying, and the difference is greater on heavy than on light rations. The increment of heat production during standing is affected by the individuality of the animal and by the kind of feed consumed. An approximate partial analysis of the heat production of the animal into its principal factors is attempted. The average energy expenditure consequent upon the consumption of 1 kg. of dry matter is reported for 11 different feeding stuffs. The expenditure of energy arising from the consumption of the coarse feeds is not on the whole materially greater than in the case of the concentrates. The increased muscular work of the digestive organs appears to be a relatively small factor of the increased heat production. A scrub steer showed a somewhat greater increment of metabolism consequent upon feed consumption than did a pure-bred beef animal."

A summary of the average net energy values obtained in these experiments for the following feeding stuffs is given as timothy hay, 1,072 calories; red clover hay, 1,039; mixed hay, 934; alfalfa hay, 752; maize stover, 887; maize meal, 1,893; wheat bran, 1,334; grain mixtures, 1,737 and 1,848; and hominy chop, 2,157 calories per kilogram of dry matter.

A method is outlined for computing net energy values, in the absence of direct determinations, from metabolism experiments or from the data of ordinary feeding tables.

Related experiments of others are reviewed, and a bibliography of cited literature is appended.

Feeding experimental animals on grass tree, C. J. POUND (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, p. 112*).—Two 12-month-old calves were fed chopped grass tree varying in amounts from 3 to 6 lbs. per day, mixed with a small quantity of bran, without deleterious effects. The calves gained in weight.

Origin of the Aberdeen-Angus and its development in Great Britain and America (*Chicago: American Aberdeen-Angus Breeders' Assoc. 1914, pp. 36*).—A history of this breed of cattle, together with notes on the principal families. A bibliography of literature on the breed is included.

The story of the Herefords, A. H. SANDERS (*Chicago: The Breeder's Gazette, 1914, pp. 1087, pl. 1, figs. 278*).—An account of the origin and development of the breed in Herefordshire, and a sketch of its early introduction into the United States and Canada and subsequent rise to popularity in the western cattle trade, with sundry notes on the management of breeding herds.

Sheep breeding, F. W. WILSON (*Arizona Sta. Rpt. 1914, pp. 352-356, 358*).—A brief report is given of the sheep breeding experiments which have been in progress since 1906. In these experiments the Tunis, Shropshire, Hampshire, Rambouillet, Oxford, Dorset, Navajo, and native breeds have been used in various combinations. It is said that the first generation of Tunis and native half-blood is the most promising cross to date.

A table is given showing the average weights of the sheep at birth, six months, and one year, with the weight of the fleece for all crosses numbering six or more individuals. A total of 448,223 lbs. of wool shipped in February and March weighed 452,852 lbs. when sold in the Boston market, due to the gain in moisture.

Are sheep profitable in Maine? C. D. WOODS (*Maine Sta. Bul. 236 (1915), pp. 59-61*).—This is a preliminary report of an experiment undertaken at Highmoor Farm for the purpose of ascertaining whether or not hay and pasturage can be profitably marketed through sheep under Maine conditions.

Production and price of wool, E. PAYEN (*Écon. Franc., 43 (1915), I, No. 3, pp. 70-72*).—This is a statistical review of the wool production of the world.

The value of distillers' dried grains in swine feeding operations, E. S. GOOD and W. V. SMITH (*Kentucky Sta. Bul. 190 (1915), pp. 5-18*).—The object of this experiment was to determine the value of distillers' dried grains in swine-feeding operations as a supplement to pasture, to corn meal and pasture, and to corn meal fed in the dry lot.

Four lots of from 10 to 15 shoats, weighing approximately 68 lbs., were fed 73 days as follows: Lot 1, distillers' dried grains and pasture (oats, rape, and pigweed); lot 2, corn meal and pasture; lot 3, corn meal and distillers' dried grains 5:1, and pasture; and lot 4, corn meal and distillers' dried grains 5:1 in dry lot. They made average daily gains of 0.456, 0.931, 1.027, and 0.883 lbs. per pig, consuming 3.68, 3.44, 3, and 4.44 lbs. grain per pound of gain, at a cost of 4.97, 4.95, 4.27, and 6.32 cts. per pound of gain (corn meal costing \$28.78 per ton, distillers' dried grains \$27 per ton) for the respective lots. Figuring that 85 per cent of the fertilizing constituents of the different feeds passed through the animals, it is estimated that the total value of the manure was \$14.72, \$8.99, \$12.24, and \$10.40 for the respective lots, or about 41 cts. for each 100 lbs. of grain fed.

The pigs did not relish distillers' dried grains alone, as they ate on the average only 1.68 lbs. daily, although given all they would eat. As a grain supplement to pasture, however, distillers' dried grains proved of value in this experiment as a gain of nearly 0.5 lb. per head per day was obtained on an otherwise unprofitable pasture.

The value of wheat as a feed for swine, E. S. GOOD and W. V. SMITH (*Kentucky Sta. Bul. 190 (1915), pp. 19-27*).—The object of this experiment was to determine the value of wheat alone and with a nitrogenous supplement as a feed for swine, and also to determine the form in which wheat can be fed to the best advantage.

Four lots of about 10 shoats each, weighing approximately 105 lbs., were fed 62 days as follows: Lot 1, whole wheat soaked; lot 2, ground wheat dry; lot 3, ground wheat soaked; and lot 4, ground wheat and tankage 14:1. They made 1.5, 1.72, 1.68, and 1.78 lbs. average daily gain per pig, consuming 4.26, 3.74, 3.82,

and 3.59 lbs. of grain per pound of gain, costing 5.67, 5.36, 5.47, and 5.38 cts. per pound of gain, and giving a net profit per bushel of grain of 39.7, 50.1, 47, and 50.8 cts. for the respective lots. It is concluded that ground wheat fed dry gave slightly better results than ground wheat soaked; that it pays to grind the wheat; and that little profit was realized in adding tankage to the ground wheat in the proportion of 1:14. It is believed that a proportion of 1:10 would have been more satisfactory. It is estimated that for each bushel of wheat fed 21.5 cts. worth of fertilizer was produced. It is said that more economical results would have been obtained had these pigs had the run of a forage crop and the grain limited to about 2.5 per cent of their weight for two or three weeks before going to the market.

Pig feeding experiments, J. M. SCOTT (*Florida Sta. Rpt. 1914, pp. XIX-XXII*).—Three lots of five 87-lb. pigs each were fed 31 days as follows: Lot 1, shelled corn and Dwarf Essex rape; lot 2, shelled corn and ground velvet beans 3:1 and rape; and lot 3, shelled corn and ground velvet beans 1:1 and rape. They made average daily gains of 0.31, 0.23, and 0.2 lb. per head, consuming per pound of gain 18.35, 24.59, and 28 lbs. of feed, at a cost of 11.1, 13.4, and 12.6 cts. per pound of gain for the respective lots.

Five lots of four 63-lb. pigs each were fed 30 days as follows: Lot 1, corn alone; lot 2, corn and cracked velvet beans 3:1; lot 3, corn and cracked velvet beans 1:1; lot 4, corn and cracked velvet beans 1:1 and iron sulphate; and lot 5, corn and cracked velvet-bean meal 3:1 and iron sulphate. They made average daily gains of 0.46, 0.63, 0.56, 0.52, and 0.53 lb. per head, consuming per pound of gain 6.55, 4.8, 5.37, 5.74, and 5.63 lbs. of feed, at a cost of 11, 6.7, 5.7, 6.1, and 7.9 cts. per pound of gain for the respective lots.

Care of brood sow, W. HISLOP (*Washington Sta. Popular Bul. 84 (1915), pp. 4, fig. 1*).—This gives general information on brood-sow management.

Swine husbandry in Canada, J. B. SPENCER (*Canada Dept. Agr., Branch Live Stock Comr. Bul. 17 (1914), pp. 72, figs. 35*).—This is a general discussion of the methods of breeding, feeding, care, and management of hogs in vogue in Canada, with especial reference to bacon production.

Studies on the physiology of reproduction in the domestic fowl.—VII, Data regarding the brooding instinct in relation to egg production, R. PEARL (*Jour. Anim. Behavior, 4 (1914), No. 4, pp. 266-288; abs. in Maine Sta. Bul. 234 (1914), pp. 284, 285*).—This paper presents data regarding variations in the manifestations of the brooding instinct in fowls. It is shown that "broodiness normally constitutes one element in the cyclical reproductive activities of the female. It recurs with greater or less regularity following periods of laying. The degree of intensity of the brood instinct, both in respect of its objective manifestations and in respect of its physiological basis, may vary considerably at different times in the life of the same individual. Broodiness in the domestic fowl is not necessarily connected with any particular season. It may occur entirely outside the regular breeding season. While ordinarily broodiness is preceded by the laying of a 'clutch' of eggs, this need not necessarily be so. Cases are cited in which well-marked broodiness occurs without antecedent laying. Well-marked broodiness behavior may in certain cases disappear very quickly. The manifestations of the brooding instinct are apparently closely connected with the functional activity of the ovary, though the precise nature of the connection has not yet been analyzed."

Studies on the physiology of reproduction in the domestic fowl.—X, Further data on somatic and genetic sterility, MAYNIE R. CURTIS and R. PEARL (*Abs. in Maine Sta. Bul. 234 (1914), p. 287*).—In a study to determine the

cause for partial or complete sterility in the fowl it was found that "birds which are hereditarily high layers may fail to make good performance records because for some anatomical reason it is impossible for yolks to enter the oviduct. Birds which ovulate, or return partly formed eggs, into the body cavity usually show the nesting instinct. The nesting records show a rhythm similar to egg records of normal birds and it seems probable that they are the normal resultant of the ovulation."

It is stated that "in case of stoppage of the duct at any level the duct on both sides of the point of stoppage passes through the same cyclic changes coordinated with the cyclic changes in the ovary as a normal unobstructed duct. The duct functions only as far as it receives the stimulus of the advancing egg. Absence of pressure from the funnel does not prevent or apparently greatly retard ovulation. Increased internal pressure may therefore be the most important factor in normal ovulation. Yolks of partly or fully formed eggs may be absorbed rapidly and in large numbers from the peritoneal surface without causing any serious derangement of normal metabolic processes."

Some physiological observations regarding plumage patterns, R. PEARL and ALICE M. BORING (*Science, n. ser.*, 39 (1914), No. 995, pp. 143, 144; *abs. in Maine Sta. Bul.* 234 (1914), pp. 281-283).—A study was made of the plumage pattern of Barred Plymouth Rock chickens to determine the manner in which the Mendelian factor, representing the barring pattern, operates physiologically.

It was found that "all feather follicles are not capable of continually producing successive feathers for an indefinite time. In the case of the general body plumage a feather is usually not regenerated more than about three times. The precise number of successive regenerations varies with different birds and different feathers. Wing primaries seem to possess the maximum regenerative capacity. After about the third removal in the case of body feathers the follicle usually remains in a perfectly quiescent condition, taking no steps whatever toward the regeneration of a new feather.

"This failure to regenerate is, however, very definitely related to the natural molt of the bird, and in the following way: A follicle which has been absolutely inactive for a long period of time (e. g., six months) preceding the natural autumn molt of the bird produces a new feather in connection with the molt, in the same manner as does any other follicle of the body. In other words, the process of natural molting reactivates the follicle which had been brought into a quiescent state by successive feather removal.

"The precise pattern exhibited by a particular feather is, in the usual course of events, reproduced each time a feather is produced by that follicle with extreme fidelity of detail. If, however, the feather is removed from the follicle as soon as it is fully grown, thus forcing continued regenerative activity of the follicle, the pattern tends progressively to be broken up, and probably will ultimately be entirely lost as a definite pattern. The experiments have not yet gone far enough to enable us to speak positively on this latter point. A progressive breaking up of an originally definite pattern is, however, very clearly shown in a number of cases. The behavior of the color pattern in successively regenerated feathers suggests, as a working hypothesis, that the pattern factor or gene is possibly represented in each follicle by a strictly limited amount of material, and that when this is used up the pattern is lost.

"The secondary sexual feathers of the male, such as the saddle hangers, only appear as adult plumage. The same follicles which bear these feathers produce, as juvenile plumage, undifferentiated body feathers. The formation of these secondary sexual feathers is not necessarily dependent upon any normal

molt. If the juvenile feather is removed from the follicle the next feather produced by that follicle will be the secondary sexual feather, and not a feather of the juvenile type. After that all further regenerations are of the sexually differentiated feather."

The measurement of changes in the rate of fecundity of the individual fowl, R. PEARL (*Science, n. ser., 40 (1914), No. 1028, pp. 383, 384; abs. in Maine Sta. Bul. 234 (1914), pp. 283, 284*).—This is a preliminary paper calling attention to a method of measuring and representing graphically changes in the intensity of ovarian activity, as indicated by rate of ovulation in the domestic fowl.

It is said that "by a simple statistical expedient it is possible to represent the changes in rate of fecundity in an individual bird as a continuous curve, of which the ordinates represent the rates of egg production on a percentage scale (0 to 100) at the time intervals plotted as abscissæ. This is done by taking, as the rate of fecundity for any given day P_n , the percentage which the actual number of eggs laid by the bird during the 21 days, of which P_n is the central day, is of 21. Put as a formula, if—

RP_n = rate of fecundity (or ovarian activity as indicated by ovulation) on the day P_n ,

l = an egg produced, and

Σ denotes summation between the indicated limits, we have—

$$RP_n = \frac{100 \left(\sum_{P_n-10}^{P_n+10} l \right)}{21}$$

"The rates so calculated for each successive day may be plotted as a curve. . . .

"Applying this method to records of one, two, and three-year-old hens many interesting and novel points regarding ovarian activity, as expressed in ovulation, may be made out. The long-period secular cycles of production appear much more clearly and precisely than in flock mass statistics. The steady diminution in maximum rate of fecundity per unit of time after the first spring cycle in the bird's life is very strikingly shown in the great majority of cases.

"This method of measuring fecundity opens the way to the attacking in the individual of a number of problems which hitherto have only been amenable to indirect, statistical treatment. Such, for example, are the questions of relation of size of egg to rate of fecundity, the relation between fertility (in the fowl readily measured by hatching quality of eggs) and fecundity."

Poultry department, V. R. McBRIDE (*Washington Sta., West. Wash. Sta. Mo. Bul., 2 (1915), No. 10, pp. 26-30, fig. 1*).—From records kept of the sub-station flock, it is estimated that the average cost of feed for a laying hen is \$1.50 per hen per year, for the general-purpose breeds, such as Orpingtons, Plymouth Rocks, and Langshans. The cost for Leghorns and Auconas has been \$1.35 each. The average cost of producing eggs has been 16 cts. per dozen.

In incubating and brooding trials, out of 3,000 eggs incubated 2,300 chicks were hatched. The loss of chicks during the brooding period was 8 per cent. It was found that chicks hatched from eggs weighing from 24 to 27 oz. per dozen were more vigorous and grew more rapidly than those hatched from abnormally large or very small eggs. The small eggs were about equal to the larger ones in fertility, but the chicks hatched from these were lacking in vitality. The abnormally large eggs, weighing more than 27 oz. per dozen, were low in fertility and did not hatch well.

Three lots of 40 White Leghorn pullets each were fed during a six months' period similar rations, except that cracked corn, rolled barley, and whole oats were compared as supplements to whole wheat in the grain mixture. The amount of grain consumed by the respective lots was 1,040, 1,060, and 1,000 lbs.; the amount of mash consumed 400, 360, and 430; the total cost of feed \$26.40, \$23, and \$23.60; the number of eggs laid 2,975, 2,974, and 2,574; the gain in weight 27, 32, and 17 lbs., respectively. Out of 200 eggs incubated in lot 1, 185 were fertile, from which 153 chicks were raised; lot 2, 180 fertile and 150 chicks raised; lot 3, 168 fertile and 133 chicks raised.

Two lots of 50 White Leghorn and Ancona cockerels each were fed for 12 days a fattening ration as follows: Lot 1, corn meal, wheat bran, meat meal, and skim milk, 3:1:1:12.5; lot 2 was given the same ration as lot 1 except that 1 lb. of bean meal was used instead of the meat meal. The net gains were 21 and 32 lbs. and the cost per pound gain 6.5 and 4.5 cts., respectively.

Eight-weeks-old Barred Plymouth Rock, White Orpington, and Black Langshan cockerels were fed a fattening ration for two weeks. The average cost of producing 2 lb.-broilers in this was 12 cts. per pound, including labor.

[Poultry], V. R. McBRIDE (*Washington Sta., West Washington Sta. Mo. Bul., 1 (1914), No. 7, pp. 10-13, fig. 1*).—A system of line breeding for poultry is described. Suggestions are given for the selection of eggs for incubation. A brief discussion of types of incubators and their handling is included.

The truth about the poultry business, CONBOIE (*San Francisco: Author, 1914, pp. 160, pls. 12*).—This is a book of practical information on the breeding, feeding, care, and management of poultry.

Making poultry pay, E. C. POWELL (*New York: Orange Judd Co., 1907, pp. XII+307, pl. 1, figs. 118*).—This booklet deals with the breeding, feeding, care, and management of poultry for commercial purposes.

How I breed the 200-egg hen, T. BARRON (*Philadelphia: Tom Barron Publishing Co., 1914, pp. 79, figs. 19*).—This booklet contains practical information on the feeding and care of poultry for profit.

Building up a trade in pure-bred poultry, R. SEARLE and T. E. QUISENBERRY (*Mountain Grove, Mo.: American School Poultry Husbandry, 1914, pp. 38, figs. 5*).—This booklet gives practical information on methods of marketing poultry-breeding stock, and poultry products.

Poultry keeping, AGNES KINROSS (*West of Scot. Agr. Col. Bul. 64 (1914), pp. 113-171, pls. 16*).—This bulletin contains general information on the breeding, feeding, care, and management of poultry, including chickens, turkeys, and ducks, and suggests desirable rations for both summer and winter. Methods of fattening and preparing for market are described.

Turkeys, HELEN D. WHITAKER (*Washington Sta. Popular Bul. 86 (1915), pp. 8*).—This treats of the breeding, feeding, care, and management of turkeys.

The practical production of game animals, A. BLANCHON (*L'Élevage pratique du Gibier. Paris: Larousse, 1914, pp. 284, figs. 176*).—This is a treatise on the breeding, care, and management of game animals, including birds, deer, fox, rabbits, and other animals.

DAIRY FARMING—DAIRYING.

[Dairy feeding experiments], F. W. WILSON (*Arizona Sta. Rpt. 1914, pp. 357, 358*).—Four cows on alfalfa pasture produced a total of 1,089.1 lbs. of milk during a 7-day period, while the same cows on dry feed (alfalfa hay at the rack, wheat bran 7 lbs. and rolled barley 1.5 lbs. daily) produced 1,097.6 lbs. Three of the cows gained in milk yield on dry feed and one lost. Two lots

of 9 cows each, were fed two weeks a ration of alfalfa hay, dried beet pulp, and wheat bran, lot 1 being then continued on the same feed for two weeks longer, while lot 2 was fed for two weeks on beet pulp and alfalfa hay. During these last two weeks lot 1 fell off 156 lbs. in milk yield, and lot 2 316 lbs. The loss of lot 1 is thought to be the normal loss due to advancement of the period of lactation and other natural causes. It is estimated that the actual saving by feeding beet pulp instead of beet pulp and bran was \$3.72 in two weeks.

Body form and milk yield, E. AUGUSTIN (*Flugschr. Deut. Gesell. Züchtungsk.*, No. 33 (1915), pp. 32).—A general treatise on the relation of body form to milk yield.

Holstein-Friesian makes world's dairy record (*Breeder's Gaz.*, 67 (1915), No. 13, p. 671).—It is announced that the Holstein-Friesian heifer Finderne Holingen Fayne has broken all world records for fat production by producing in 365 consecutive days 24,612.8 lbs. of milk containing 1,116.05 lbs. of fat. She freshened at 3 years and 4 months and weighs 1,450 lbs., an increase of 250 lbs. during the period.

Report of four years' work of the North Dakota Holstein cattle breeding circuit, J. H. SHEPPERD and W. B. RICHARDS (*North Dakota Sta. Bul.* 109 (1914), pp. 93-158, figs. 16).—A general account of the organization, management, and progress of the North Dakota Holstein cattle breeding circuit, which is being conducted in cooperation with the station and the U. S. Department of Agriculture. Detailed records are appended.

The development of the dairy products industry in Minnesota, M. J. ANDERSON, edited by E. V. ROBINSON and J. G. WINKJER (*Minn. Dairy and Food Dept. Bul.* 52 (1914), pp. 61, figs. 8).—This reviews the development of the dairy industry in Minnesota and discusses its present status.

Cost of milk, W. A. LINKLATER (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 10, p. 13).—From records kept during a 12-month period of a herd of from 12 to 16 head of cows, the computed cost of milk was \$9.89 per month per cow, or 3.9 cts. per quart. The cost of feed and pasture for the entire herd for the year was estimated to be \$720.16, and of labor \$770.

From experiments conducted in cooperation with a condensed milk concern, it was concluded that contamination of milk after it is drawn is the cause of inferior quality for condensing purposes rather than the feed eaten by the cow.

The useful and harmful bacteria of milk, R. PFISTER (*Milchw. Zentbl.*, 43 (1914), No. 18, pp. 466-469).—In this article the author discusses the value of kefir, kumiss, and various other sour milk drinks and differentiates between the beneficial bacteria contained in these milks and the harmful pathological bacteria often found in milk.

The devitalization of tubercle bacilli in milk by means of electricity, F. C. LEWIS (*Tuberculosis Year Book*, 1915; *abs. in Jour. Bd. Agr.* [London], 21 (1914), No. 9, p. 844).—Experiments conducted at the University of Liverpool demonstrate that electricity can be successfully applied as a sterilizing agent in milk. It is claimed that the total bacterial count is greatly reduced, all *Bacillus coli* and its allies are destroyed, tubercle bacilli are destroyed, no chemical changes in the milk can be detected, and the taste of the milk is unaltered.

Regulations governing food establishments; rules on dairies and the score-card system of dairy inspection, with suggestions to dairymen (*Agr. Com. Ohio, Bur. Dairy and Sanit. Insp. Bul.* 1 (1913), pp. 13).—This bulletin gives the rules adopted by the State of Ohio relating to dairies and the score card system of dairy inspection, with suggestions to dairymen.

Milk quality as determined by present dairy score cards, J. D. BREW (*New York State Sta. Bul.* 398 (1915), pp. 107-132, figs. 2).—The results of a com-

parative study made of the bacterial content of the milk and the scores of 34 commercial dairies as determined by the Cornell card, the official card approved by the Dairy Instructors' Association, and the New York City card, indicate that no correlation whatever exists between the quality of the milk so far as it could be determined by laboratory methods and the score as expressed by any one of the three cards. The apparent reason for this lack of relationship is that a large number of the items included on the score card have little or no effect upon the number of bacteria present in the milk, there being too great emphasis placed upon unessential factors in the score cards, with a consequent lessened emphasis upon the factors which actually do affect the milk.

While not denying the value of dairy score cards, the author believes that the results of this investigation show that present score cards can not be satisfactorily used as a means of grading milk according to quality.

Some variation was found in the relative position of the various dairies when scored simultaneously with all of the cards. In general, however, the scores secured by using the Cornell card were the most lenient, while those secured by using the New York City card were the most severe.

What causes contribute to the loss of the cream line on pasteurized milk in bottles, C. H. KILBOURNE (*Cream, and Milk Plant Mo.*, 3 (1915), No. 8, pp. 11-20).—Because of complaints that the volume of cream on bottled pasteurized milk was decreased and the distinctness of demarcation between the cream and the milk injuriously affected, tests were made by the Board of Health of New York City to determine the cause of these difficulties.

The results indicate that when milk is cleaned by a centrifugal clarifier the volume of cream in the milk is reduced from 2 to 3 per cent. It was evident that the volume of cream in bottled milk is influenced by various factors, among which are included the temperature to which the milk is heated, the length of time for which milk is held at the high temperature, the temperature of the heating medium with which the milk comes in contact during the heating process, the clarification of the milk, the type of apparatus used in treating the milk and the amount of agitation to which the milk is subjected, especially when hot. This last factor appears to be one of the most important. It is believed that under the most favorable circumstances heating to 145° F. and holding for 30 minutes may be done without any injurious effect upon the cream line, but it has been deemed best to reduce the required temperature to 142° in order to allow for uncontrollable factors which may tend to offset the volume of cream.

Factors influencing the quality of milk for condensing purposes, W. A. LINKLATER (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 9, pp. 2-5).—From studies made of the station dairy herd fed rations consisting of alfalfa hay and grain, supplemented by green oats and vetch, mangels, turnips, kale, and corn silage, it was concluded that variations in the quality of the milk were due to bacteria getting into the milk after it was drawn rather than to the kind of feed used, provided this was of good quality.

It was found that following rain, when the yard became muddy, the bacterial count increased. The cows got their flanks and udders soiled with mud, and in spite of careful wiping the quality of the milk was lowered. Poorly washed and unsterilized milk utensils were demonstrated to be a source of infection. The bacterial count increased from two to three times in the course of three or four hours even when the milk was aerated and cooled down to a temperature of about 60° F. A lowering of the quality of the milk followed exposure to dust, the drop in quality being especially marked on windy days, or when the feeding of silage, straw, or hay was done at the time of milking.

Care of cream on the farm and ice house construction, C. W. FRYHOFER (*Bul. Vt. Dept. Agr., No. 20 (1914), pp. 31, figs. 9*).—The subjects discussed in this bulletin are the relation of the quality of butter to the quality of cream, the importance of cleanliness, temperature, thickness of cream, frequency of delivery at the creamery, methods for cooling cream on the farm, specifications for making the cream-cooling box, ice storage, ice houses, variations in the patron's cream test, relations between the patron and creamery, and overrun.

Two factors causing variation in the weight of print butter, H. M. PICKERILL and E. S. GUTHRIE (*New York Cornell Sta. Bul. 355 (1915), pp. 99-111, figs. 3*).—As the result of their studies of the causes of variation in the weight of print butter the authors found that "the variation of pore space, which ranges from 0.5 to over 6 per cent in freshly made butter, is important in the printing process. Print butter gradually loses weight in storage. The rate of loss depends principally on the temperature and humidity of the storage room. If the temperature is kept down to 50° F. and the humidity is kept above 90 per cent, at least a month, and perhaps much longer, will be required for the shrinkage to approximate the limit set by law, provided the prints are packed in boxes. If the temperature is 60° or above and the humidity is 85 per cent or below, the shrinkage will approximate the limit set by law in a space of 10 days to 2 weeks, even if the prints are packed in boxes.

"The degree of shrinkage is not inversely proportional to the weight of the wrapper used, as is generally supposed. The degree of shrinkage decreases to a considerable extent when the prints are placed in cartons. The other two methods of packing, however, leaving the prints dry after placing them in boxes or sprinkling them with water, produce about the same effect on the degree of shrinkage. In the average small-store refrigerator the loss will approximate the limit set by law in a space of 10 days when the prints are piled loosely on shelves."

Mechanism of overrun in the manufacture of ice cream, M. MORTENSEN (*Cream and Milk Plant Mo., 3 (1915), No. 8, pp. 21, 22*).—The author discusses the factors determining the amount of overrun in the manufacture of ice cream, among them the viscosity and temperature of the cream used, the temperature of the ice cream when drawn from freezer, the fillers used, and the temperature of the brine.

It is stated that pasteurization reduces the viscosity of milk and cream, and pasteurized cream, if used soon after pasteurization, will not retain as much air and the yield is accordingly reduced. The body of the ice cream is also coarser. Pasteurized cream, due to its lower viscosity, affords less resistance to churning, and hence during the freezing process butter particles are formed, which, in turn, reduce the viscosity of the mix and the yield. By holding the cream at within a few degrees of freezing temperature for not less than 24 hours after pasteurizing, the viscosity is increased and the formation of butter particles is less prominent.

A cream produced from milk containing small fat globules is deemed most satisfactory for ice-cream making, hence the value of strippers' milk and of cream from milk produced by the Holstein breed. Homogenization increases viscosity, and such cream is frozen without the formation of butter granules and therefore a greater yield and a smoother ice cream is obtained.

It is said that the principal advantages obtained from fillers are the increase in viscosity of the mix, the prevention of formation of butter particles during the freezing process, and the fact that they add strength to the cream films surrounding the moisture particles, thus insuring a body possessing better keeping properties. It is thought that fillers do not increase the yield obtained, but

it is believed possible to increase the yield by prolonging the freezing process, and thus incorporating the air into the cream to which the filler has been added.

Sanitary code for ice cream manufactories ([*Columbus*], *Ohio: Agr. Com. Ohio, Bureau of Dairies, 1914, pp. 4*).—This gives the sanitary code of Ohio for ice-cream manufactories.

Method of making Swedish Emmental and large-celled Swedish Estate cheese, L. F. ROSENGREN (*Centralanst. Jordbruksförsök Flygbl., 47 (1914), pp. 7, figs. 6*).—The author gives detailed directions for the making of these two varieties of cheese, and discusses various factors which influence the texture of the cheese, notably the feed and the quality of the milk.

Fat content standards for Danish types of cheese, ORLA-JENSEN (*Milchw. Zentbl., 43 (1914), No. 22, pp. 540-542*).—This article discusses the fat content of various types of Danish cheese.

Fat content in the dry matter of various sorts of Italian cheese, G. FASCETTI (*Milchw. Zentbl., 43 (1914), No. 22, pp. 538-540*).—This article discusses the fat content of Grana, Gorgonzola, and other types of Italian cheese.

Fat content of Swiss Emmental cheese, R. BURRI (*Milchw. Zentbl., 43 (1914), No. 23, pp. 556-558*).—Analyses taken of 641 samples of Swiss Emmental cheese show that the average fat content in the dry matter ranges between 45 and 50 per cent, although some samples test as low as 40 per cent.

VETERINARY MEDICINE.

An analysis of the problem of the minimal lethal dose and its relationship to the time factor, G. DREYER and E. W. A. WALKER (*Biochem. Ztschr., 60 (1914), No. 2-3, pp. 112-130; abs. in Lancet [London], 1914, I, No. 15, pp. 1023-1027; Jour. Amer. Med. Assoc., 62 (1914), No. 19, p. 1509*).—"In warm-blooded animals dosage (D) must be calculated in relation to the body surface according to the expression $D = \frac{d}{W^{0.75}}$, where D is the 'surface dose' of the drug, toxin, or antitoxic substance used, d represents the actual quantity administered, and W is the weight of the animal in grams. No method, however, at present exists by which a true comparison of the relative toxicity of different substances (or of different samples of the same substance) can be instituted. The methods hitherto employed depend on the selection of an arbitrarily fixed weight of animal and lethal time, and do not afford a rational basis for the accurate measurement and standardization of drugs, toxins, and antitoxins.

"The formula here proposed, viz. $\frac{1}{D_0 - a} - \frac{1}{D_1 - a} = k(T_0 - T_1)$, offers a simple means of making such measurements. In this formula D_0 and D_1 are the concentrations of the drug or surface doses, corresponding to the times T_0 and T_1 in which the death of the animal (or other desired effect) occurs; a is a figure representing the 'noneffective' dose of the substance employed, and k is a constant to be determined for the particular substance and species of animal under investigation. The formula states that to every equal increment in time there corresponds a definite decrease in the 'active dose' ($D - a$).

"This formula is here shown to afford a satisfactory expression for all the varied and diverse experimental data to which it has been applied. The use of the formula renders it possible not only to carry out the comparison desired, but also to make use of animals of every size over a wide range of weight within a species, and all observed death times, in the standardization of toxic substances, antitoxins, and the like. By this means a great saving both of time

and animal material is introduced, since an equal value, independent of the actual lethal time and weight of individual animal, can now be attached to all the experimental data.

"The results obtained will also possess a greater validity and a wider application than it has hitherto been possible to attain by the use of an arbitrary death time and a fixed standard weight of experimental animal."

See also previous work (E. S. R., 31, p. 80).

Studies in anaphylaxis, R. WEIL (*Jour. Med. Research*, 30 (1914), No. 3, pp. 299-364, figs. 33).—This series of studies includes the relation between antibody content and lethal dose in anaphylaxis, the function of circulating antibody and the avidity of cellular antibody, the relation between partial desensitization and the minimal lethal dose in anaphylaxis, and the persistence of intracellular antigen as a factor in immunity. Each of the problems is said to have an important bearing on the understanding of certain aspects of immunity.

A theoretical discussion of the share of intracellular antigen in immunity and in desensitization is appended.

The relation of vaccine therapy to veterinary practice, R. E. SPLINE (*Amer. Vet. Rev.*, 45 (1914), Nos. 1, pp. 19-29; 2, pp. 161-177).—A detailed exposition.

Observations upon the standardization of bacterial vaccines by the Wright, the hemocytometer, and the plate-culture methods, E. GLYNN, MILDRED POWELL, A. A. REES, and G. L. COX (*Jour. Path. and Bact.*, 18 (1914), No. 3, pp. 379-400, pls. 3; *abs. in Lancet [London]*, 1914, I, No. 15, pp. 1028-1032, figs. 4; *Jour. Amer. Med. Assoc.*, 62 (1914), No. 19, p. 1509).—"Four methods of standardizing vaccines have been compared—Wright's and Allen's modification of it, the hemocytometer, and the plate culture. The gravimetric will be considered on a future occasion.

"The most scientific method of enumerating the bacteria is in some form of hemocytometer chamber. An optically plane cover slip must be used with such apparatus, for it is recognized as essential when counting blood, and is still more essential when counting bacteria, where accuracy is of greater importance. Owing to the small free working distance of oil-immersion lenses, most optically plane cover slips are too thick.

"Two types of hemocytometer chamber may be employed: (a) The ordinary chamber 0.1 mm. deep with an optically plane cover slip 0.13 mm. thick. This is suitable for all oil-immersion lenses with a free working distance of 0.17 and some of 0.15 mm.; (b) a chamber of 0.02 mm. deep with a special safety trench 2.5 mm. wide, and optically plane cover slip 0.18 mm. thick. This is suitable for all achromatic oil-immersion lenses, even if the free working distance is as low as 0.09. The 0.02 mm. chamber is preferable, for the following reasons: (a) Almost all the bacteria settle at the bottom in 15 minutes, when accurate counts can be made, whereas in the 0.1 chamber a considerable number are still moving after half an hour; (b) bacteria adhering to the under surface of the cover slip or still floating in the chamber are much more easily enumerated; (c) the optical definition of the bacteria is better owing to the smaller quantity of fluid; (d) the free working distance is greater, the cover slip more durable. A weak solution of carbol thionin is the best diluting and staining fluid; unlike Giemsa it is quite free from precipitate and stains more intensely.

"In order to ascertain whether the Wright film or the 0.02 hemocytometer chamber was more accurate, two observers standardized the same emulsion by each method, and took as the practical test of accuracy the percentage deviation from the arithmetic mean of their two counts. The error for each method, as estimated in a larger series of prepared emulsions of staphylococcus, strep-

tooccus, and colon by three pairs of observers, is remarkably similar, being on the average less than 5 per cent with a minimum of 0.5 per cent, and a maximum of 21 per cent for the chamber method, and more than 15 per cent with a minimum of 1.1 per cent and a maximum of 54 per cent for Wright's. The fact that less time was spent on counting 64 squares by the chamber method than 75 or 50 fields by Wright's still further demonstrates the superiority of the former.

"The 0.1 mm. chamber is a little less accurate than 0.02, partly owing to the difficulty of correctly ascertaining to which squares the bacteria adhering to the under surface of the cover slip belong and partly owing to the greater amount of Brownian movement. Wright's method usually greatly underestimates the strength of the bacterial emulsion, sometimes by 100 or even 200 per cent. The main reasons are, first, because large numbers of bacteria are left behind at the beginning of the smear; and, second, because small groups of bacteria mix up with blood platelets and leucocytes and are drawn to the end of the smear, where they may be unnoticed unless specially looked for with a low power. Allen's modification of Wright's method has the same defects as the original; it underestimates the emulsion to the same extent, and the error is, if anything, larger. The plate-culture method is cumbersome, and time is wasted in waiting for the colonies to develop. It also seriously underestimates the strength of the bacterial vaccines, first, because of the impossibility of obtaining a homogeneous emulsion, especially in the case of the cocci; second, because even in comparatively young cultures a large number of bacteria are moribund or dead and fail to develop into colonies. Working with most carefully prepared emulsions, we found that coli were underestimated about 5 per cent in cultures four hours old, and about 60 per cent in cultures 24 hours old, while the staphylococci were underestimated by 50 and 100 per cent, respectively, the discrepancy being greater owing to the large number of diplococci in the younger cultures.

"This paper has been written because we believe it is the duty of the bacteriologist to standardize and dispense his vaccines with as much care as is exercised by the pharmacist in standardizing and dispensing his drugs. Scientific vaccine therapy will be advanced by scientific exactness."

Observations on hemolysin production by the streptococci, H. W. LYALL (*Jour. Med. Research*, 30 (1914), No. 3, pp. 515-532, fig. 1).—At the outset stress is laid upon the fact that in spite of extensive studies on this topic our understanding of the factors responsible for the grave toxic conditions arising from streptococcal infections is still far from satisfactory. This work was therefore conducted with a view of discovering any possible correlation between hemolysin production and pathogenicity, and determinations were made of the hemolytic titer of several strains of streptococci.

It was found that "the hemolytic titer does not afford any absolute criterion of virulence. The production of a potent hemolysin in broth cultures is dependent on the nature and proportions of enriching substances, the reaction of the medium, and the time of incubation. The hemolysin appears to be closely associated with the bacterial bodies and not to be in solution. The hemolysin does not appear to be in the nature of an enzyme. The hemolysin is destroyed by a temperature of 56° C. for 30 minutes. It disappears within 49 hours at incubator temperature.

"Normal sera of sheep, guinea pig, rabbit, cow, and man contain appreciable amounts of antistreptolysin. Salvarsanized sera possess a markedly increased inhibitory power on the hemolytic action of streptococci. Hemolysin production is inhibited by the addition of sugar. This occurs most uniformly in the

case of dextrose. It does not appear to be definitely associated with the amount of acid produced."

On the production of precipitins, L. HEKTOEN (*Jour. Infect. Diseases*, 14 (1914), No. 3, pp. 403-410, figs. 5; *abs. in Jour. Amer. Med. Assoc.*, 62 (1914), No. 25, p. 1991).—"By giving rabbits intraperitoneal injections of increasing quantities of serum or blood on three successive days a serviceable precipitating serum may be produced in about 15 days. The same quantity of antigen injected at one time also appears to give good results. The curve of the precipitin in such cases is like the simple antibody curve following a single injection of other antigens. The injection of whole blood may be more advantageous in producing more precipitins for blood proteins in general than the injection of serum only. The injection of washed human corpuscles gives rise to precipitins for human serum."

Further observations on the presence of antibodies for *Micrococcus melitensis* in the milk of English cows, S. L. CUMMINS, C. J. COPPINGER, and A. L. URQUHART (*Jour. Roy. Army Med. Corps.*, 23 (1914), No. 1, pp. 36-41).—In a series of seven cows examined for agglutinations two gave positive results and one of these was found to agglutinate *M. melitensis* in dilutions varying from 1:250 and 1:1,000 at different times. The milk of this cow was also investigated for opsonins and deviating substances, and it was found that "the milk, whey, and blood serum of the cow behaved toward *M. melitensis* in a manner comparable to the body fluids of animals suffering from, or immunized against, this organism. Due allowances were made for differences in concentration of 'antisubstances' and degrees of immunity."

Can bacteria circulating in the blood be eliminated through the wall of the intestine? H. BEITZKE (*Ztschr. Hyg. u. Infektionskrank.*, 78 (1914), No. 2, pp. 228-242).—The experiments were conducted with rabbits, each animal receiving in the ear vein six loopfuls of a 4- to 8-day-old *Bacillus prodigiosus* culture grown on potato. About one hour after the injection the micro-organisms were noted in the bile. At the same time and in some instances earlier *B. prodigiosus* was found in other parts of the intestine, but was never noted in the stomach. In most of the cases the organisms were found in the ileum and cecum. Sections of organs, but more especially parts of the alimentary tract, were examined microscopically and the bacilli were never noted alone but always inclosed in cells, mostly in leucocytes and in the liver in Kupffer cells. This supports the theory that leucocytes aid in the transportation of organisms into the intestines.

Foot-and-mouth disease, J. R. MOHLER (*U. S. Dept. Agr., Farmers' Bul.* 666 (1915), pp. 16, figs. 7).—This is largely a revision of the Department's earlier publications on the subject.

Vaccination with Löffler's serum against foot-and-mouth disease, J. MATSCHKE (*Arch. Wiss. u. Prakt. Tierheilk.*, 40 (1914), No. 6, pp. 516-538; *abs. in Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 42, p. 707).—The results indicate that when the serum is used under the conditions specified, it will prevent an outbreak of the disease. The protection conferred, however, is not permanent. The protective value of the serum is not dependent upon the virulence of the infecting agents and 2 cc. and more of the serum when given subcutaneously will absolutely prevent the occurrence of the disease.

Tetanus: Its prevention and treatment by means of antitetanic serum, A. MACCONKEY (*Vet. Jour.*, 70 (1914), No. 473, pp. 555-576).—An account of tetanus and its preventive and curative treatment by means of antiserum.

Regarding tubercle bacilli in the circulating blood of bovines, especially after injecting tuberculin, L. BRANTE (*Ztschr. Infektionskrank. u. Hyg. Haus-*

tiere, 16 (1914), No. 3, pp. 187-194).—No tubercle bacilli could be noted in the blood of 50 tuberculous cows, 3 to 14 years old, under ordinary conditions, during the febrile stage, or after subcutaneous injections of tuberculin. Consequently, there seems to be no reason to suspect that there is great danger of liberating tubercle bacilli as a result of injecting tuberculin and causing infection of the blood.

Tuberculosis, J. M'FADYEAN (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 3, pp. 218-234).—A discussion of the measures which ought to be put in force against tuberculosis, prefaced by a short examination of the evidence for and against the view that the disease is transmissible to man. The subject is dealt with under the headings of transmissibility of bovine tuberculosis to man; types of tubercle bacilli; the eradication of bovine tuberculosis; measures necessary to safeguard human health; and measures to be taken against breeding cattle which have reacted to tuberculin, from the point of view of international trade.

"There is one, and only one, method by which tuberculosis can be eradicated from a herd, namely, that which relies upon the systematic use of tuberculin for diagnosis, and which requires the permanent separation of nonreacting animals from those which have not been tested or which have reacted."

Tuberculosis, O. MALM (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 3, pp. 234-237).—A reply to the above, and a discussion in regard to the effectiveness of the various systems for eradicating tuberculosis and the results of combating tuberculosis in Norway, where the system is said to be more rigorous than in any other country.

"The herds in Norway number somewhere about 160,000, and the number of cattle about 1,000,000. The herds are thus small, many of but from one to four head, and most between 10 and 20 animals; only a few herds number up to 100 and more. It is clear that in herds that are small and which largely live on extensive mountain pastures tuberculosis must be comparatively rare, and that, therefore, the expenses for the owners in isolating, cleansing the buildings, and slaughtering tuberculous animals must be much smaller than they would be where herds are large and exclusively kept in the cattle houses. Still another peculiarity must be noted in the case of Norway. Norwegians are accustomed to drink raw milk, and in the towns milk guaranteed free from tuberculosis would command the preference. . . .

"Since 1895 up to the end of 1913 there have been tested altogether in Norway 39,672 herds and 324,422 animals; that is, from about 1,500 to 3,500 herds and from about 12,000 to about 27,000 animals each year. In 1897, of 2,136 herds, tuberculosis was found in 577, or about 27 per cent, and of 24,765 beasts 2,056 were tuberculous, or about 8.3 per cent. The number of infected herds and animals has subsequently decreased for each year in such wise that in 1912, of 3,463 herds tested, tuberculosis was found in only 288, equal to 8.3 per cent, and of 20,439 animals only 829 reacted, or about 4.8 per cent."

Tuberculosis is decreasing amongst cattle in the districts where breeding is most advanced. The subcutaneous test is believed to be as good as infallible. Milk pasteurized at 85° C. is inferior from a nutritive point of view.

It is not believed that under natural circumstances the types of tubercle bacilli are independently perpetuated. "Experience seems to show that the glandular form of children's tuberculosis, which also in a greater or smaller number of cases is due to bovine infection, is most often of a benign character, and that it is only in few instances that it goes on to a malignant form or terminates as a chronic pulmonary consumption in the adult. As not all the tuberculous children die, but many live and retain their tuberculosis until

they become adults, the fact that bovine types are found in the adults in so much smaller a number of cases than in children must undoubtedly be due to the types, during their presence in the organism from childhood and afterwards, having become transformed from bovine to human types."

The frequency of pregnancy in slaughterhouse cattle in relation to the supply of corpus luteum, C. P. McCORD (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 16, pp. 1250, 1251).—As a rule the corpus luteum of pregnancy attains a much larger size than the spurious type, but this does not seem to distinguish it, because the corpus luteum in the nonpregnant subject has frequently been found to occupy four-fifths of the entire ovary, and in pregnancy the corpus luteum is at times four times smaller than the average size for nonpregnancy. As regards variation in color as a distinguishing factor, it has been found that this is simply due to differences in the amount of blood and lutein cells. Variations in color usually stand in relation to the age of the corpus luteum.

"The cattle slaughtered in the larger abattoirs are usually range cattle, the males and females being together at all times. The greater number of the cows of such herds are at some stage of pregnancy. An examination of the ovaries and uteri was made on 40 cows appearing consecutively on the killing floors, but of two lots from different parts of the country. The cows so examined were all within the calf-bearing period, but of various ages. Of the 40 cows, 35 yielded ovaries containing corpora lutea of such size as permitted dissecting out. Of these 35 29, or 83 per cent (72 per cent of the entire number), were pregnant. The corpora lutea from these pregnant cows were not uniformly large; many were identical in size and general appearance with those from the nonpregnant animals. Others were so large as to occupy five-sixths of the entire ovary.

"From this examination it may be inferred that numerically 83 per cent of corpus luteum is derived from pregnant cows. On account of the larger yield of corpus luteum from a pound unit of ovaries from pregnant animals than from the same unit of ovaries from nonpregnant animals, because of the larger average size of the former, the proportion by weight may run as high as 90 to 95 per cent of corpus luteum verum.

"These figures may vary on an examination of a larger number of cattle, and furthermore, a seasonal variation may alter the percentage of pregnancy. If the foregoing figures at all approximate the general condition, all corpus luteum preparations are derived in a high percentage from pregnant cattle."

Hog cholera, R. M. GOW (*Arkansas Sta. Circ.* 25 (1915), pp. 8, figs. 8).—A popular description of the cause and nature of hog cholera and methods of vaccinating hogs against the disease. A method of preventing worms in hogs, and a recipe for a condition powder are also included.

Notes on attenuation of virus in the blood of cholera hogs to prepare a vaccine, R. GRAHAM and A. L. BRUECKNER (*Jour. Med. Research*, 31 (1915), No. 3, pp. 557-568).—The inoculation of a hog-cholera virus attenuated at 60° C. for one hour may produce hog cholera, whereas one heated for one-half hour at 60° generally produces the disease. The virus heated at 60° for one hour does not produce an immunity sufficient to protect hogs against the disease.

"The same dose of vaccine may kill, protect, or non-protect inoculated animals of the same size under similar surroundings. Virus attenuated by heat and not carbolyzed may retain the disease-producing properties of the original vaccine for at least 24 days. Attenuated virus is worthless in rendering swine immune to hog cholera."

The treatment of hog cholera with methylene blue, MARTENS (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 28, p. 397).—Four large hogs affected with acute hog cholera received 0.75 to 1 gm. of methylene blue dissolved in water

and mixed with milk, daily. On the fourth day of medication a distinct improvement was noted, and after three weeks the animals had apparently recovered with the exception of a kind of weakness of the spine.

Combating hog cholera in North America, K. SCHERN and C. STANGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1914), No. 1-2, pp. 27-55, figs. 4).—A concise statement regarding the methods in use for combating hog cholera in the United States, especially in the State of Iowa, including the use of serum and virus serum, and the cost of production. The results obtained in the United States by the use of the serum both in healthy and diseased herds are discussed and analyzed with much detail.

Combating hog cholera in Germany, K. SCHERN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1914), No. 3, pp. 139-153).—The conditions in Germany and the United States in regard to combating hog cholera are compared and reasons are given why the successes are not so great in Germany as anticipated. The measures in vogue in the State of Iowa, including extension work, are described.

A guide to the dissection of the blood vessels and nerves of the pectoral and pelvic limbs of the horse, G. S. HOPKINS (*Ithaca, N. Y.: Author, 1914, pp. 54, pls. 7*).—This guide was prepared with a view to assisting students in the dissection of the blood vessels and nerves of the pectoral and pelvic limbs.

Results with the Schreiber protective and curative vaccination against strangles, KURTZWIG (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 23, pp. 399, 400).—The action of the lymph was found to be variable, but this is accounted for by the fact that mixed infections occur which also produce a variable clinical picture. Subcutaneous injections of 10 cc. of lymph will protect horses exposed to the infection. It is necessary, however, that the animal vaccinated be in good health and that it be kept in the stall for one or two days post vaccination. As a curative vaccination a single injection of 20 cc. does not suffice.

RURAL ENGINEERING.

Irrigation investigations, G. E. P. SMITH and A. L. ENGER (*Arizona Sta. Rpt. 1914, pp. 367-372*).—In the Sulphur Spring Valley the flood discharges from Leslie Canyon were measured with the aid of a concrete submerged dam. The deductions from the results obtained are as follows:

"Flood flows of great size originate occasionally from storms on the valley slopes; flows in the canyon begin suddenly and are of short duration; the rate of loss by seepage in a sandy stream bed is high; comparatively little water from the canyon reaches the river; most of the water spreads out over grass lands and sinks into the heavy soil, a minor portion of the flow (difficult to estimate) sinks through the stream beds to the main body of ground water, and a small amount also reaches the ground water through gopher holes and joints in the soil. Most of the water flooded over the draws does not sink below the reach of the grass roots."

The results of measurements of discharge of the Santa Cruz and Rillito rivers are given.

The conclusions relative to cost of pumping for irrigation, drawn from the results of investigations on the use of oil engines for irrigation pumping are as follows: "(1) The use of Tops in place of engine distillate decreases the cost of pumping about 30 per cent. (2) The cost of pumping on a 40-ft. lift with 4 ft. depth of application varies from \$8 to \$20 per acre per year, according to whether the plant is used much or little. Under the most favorable conditions the cost of pumped water is no greater than the cost of river water. (3) The cost of pumping on a 100-ft. lift with 4-ft. depth of application varies from

\$20 to \$40 per acre. (4) The largest item of cost is the fixed charges. In order to reduce these charges the plant should be used as much as possible. One pumping plant should, if possible, serve two or more ranches."

Comparative tests of a new centrifugal pump and an old stock type showed the efficiency of the former to be one-third higher than that of the latter. The new pump was a horizontal single stage pump having two outboard ring oiling bearings, water sealed gland, vacuum-proof grease cup, nonoverloading enclosed impellor, and automatic water balance.

The drainage of irrigated land, R. A. HART (*U. S. Dept. Agr. Bul. 190 (1915), pp. 34, figs. 22*).—It is the purpose of this bulletin to present in concise form the fundamental principles upon which the reclamation of water-logged and alkali lands is based, to describe typical conditions and the best methods of treating them, and to give practical advice as to actual operations.

"Drainage practice in the arid section differs greatly from that in the humid region. . . . Drainage experience in the humid section avails little in dealing with the problems of draining irrigated lands. For this reason literature on the general subject of drainage should be used with caution, as the difference in conditions between the arid and humid regions has been clearly recognized only within the last few years."

The specific objects of draining water-logged and alkali lands are "(1) to lower the ground-water table to such a depth that the moisture and air conditions within the root zone are properly balanced, (2) to provide an outlet for percolating water, so that fluctuations of the ground-water table within the root zone will be prevented, (3) to effect rapid removal of the excess moisture resulting from spring thaws, and (4) to provide an outlet for the downward moving water used to dissolve out the injurious salts. . . .

"The most important factors affecting the design of a system of drainage for irrigated land are the source and movement of the damaging water. . . . Percolating irrigation water usually is the cause of the injury, and this may have its movement downward through the soil of the tract being irrigated, laterally through pervious strata extending back under higher lands, or upward from pervious strata having considerable depth and connecting with distant sources at a higher elevation."

In determining the quantity of water that will be developed and for which it is necessary to provide an outlet, it is stated that "for tracts up to a few hundred acres in area and having average soil and subsoil, the simplest method, and one which has proved reliable, is to determine the irrigation supply and to provide a drainage capacity of one-third that amount of water. As the size of the tract increases, however, this coefficient should be decreased. If the subsoil be clay, provision for one-fifth the irrigation supply will suffice for small tracts. In areas of a square mile or more, it is usually sufficient to provide for a run-off of from $1\frac{1}{4}$ to $2\frac{1}{2}$ cu. ft. per second for each square mile, depending upon the porosity of the soil and the duty of the irrigation water. . . . In lands [underlain by gravel] it is the area that is contributing the damaging water, not the area to be drained, that must be taken into consideration."

It is stated that in determining the required capacity of a drainage system in addition to the surface survey subsurface examinations should be made to gain information as to the nature of the soil, its stratification, water-carrying capacity, and capillarity. "In the design of an open canal the important points to be considered are the effectiveness of the drain, its carrying capacity, its mechanical construction, and its maintenance in good condition. . . . [The depth] should never be less than 6 ft., presuming that the maximum depth of flow will be 1 ft., and 8 ft. would be a better minimum. . . . A berm of not

less than 6 ft. should be left on either side of the canal and the spoil should be banked up on one or both sides. . . . It is considered good practice to give open ditches a minimum bottom width of 4 ft., except in very stiff, homogeneous clay, where it may be 3 ft."

Lumber box and cement and clay tile drains are discussed under covered drains. "The smaller-sized tile should have a fall of at least 1 ft. per 1,000 ft. and the larger sizes at least $\frac{1}{2}$ ft. Tile having an inside diameter of less than 4 in. should not be used, and even 4-in. tile should be used sparingly, usually at the extremities of small branches. Experience has shown that the use of tile less than 5 in. in diameter is not warranted by the comparative results and cost. . . . In deciding whether a large covered drain or an open canal shall be employed it is necessary to calculate the original cost of each, taking account of all auxiliary and protective devices required, and then to add to each sum an amount large enough to give an annual return, at current rates, sufficient to cover the cost of maintenance." It is stated that covered drains should never be less than 5 ft. deep and that depths of from 6 to 8 ft. are much more efficient. "In general, it may be said that the proper location of a drain depends upon the surface and subsurface topography, the nature of the soil, and the source of the damaging water."

Other sections describe protective devices for open canals and covered drains and typical problems encountered in the drainage of irrigated lands and their treatment.

In discussing the construction of drains it is stated that the most satisfactory method of constructing open canals is by means of some efficient excavating machine. In installing covered drains either hand labor or trenching machinery may be used.

The final sections deal with maintenance, subsequent treatment of land, the results and cost of drainage, and cooperative drainage. "The cost of draining ordinary sized farms having an average soil that is neither so hard as to require picking nor so soft that extreme trenching difficulties will be encountered will range from \$10 per acre to \$20 per acre, with the average between \$14 and \$15 per acre. If hardpan be present or if the soil is so finely divided and so wet as to be fluxible, the cost will run up to \$50 per acre, and even more if much sheeting is required. In a few special cases drainage of small tracts in the midst of unreclaimed lands has cost between \$75 and \$100 per acre, but these costs represent situations that would not be encountered in regular operations."

A land-drainage problem in Missouri, C. H. MILLER (*Engin. News*, 72 (1914), No. 12, pp. 579-582, figs. 2).—This article describes the solution of an extensive drainage problem, providing for the drainage of an area of 425,000 acres by means of levees, drainage ditches, and river by-passes.

Stream-gaging stations and publications relating to water resources, 1885-1913, Parts VI-X, compiled by B. D. Wood (*U. S. Geol. Survey, Water-Supply Paper 340* (1915), F, pp. XXIII+63-82; G, pp. XXII+83-94; H, pp. XXI+95-104; I, pp. XXIII+105-116; J, pp. XXI+117-129).—Data similar to those reported in the first five parts (*E. S. R.*, 32, p. 381) are given for other sections, as follows: Parts VI, Missouri River Basin; VII, Lower Mississippi River Basin; VIII, Western Gulf of Mexico Drainage Basins; IX, Colorado River Basin; and X, The Great Basin.

Winter stream measurements in western Canada, P. M. SAUDER (*Engin. News*, 72 (1914), No. 19, pp. 920-924, figs. 10).—A description is given of stream measurement work done by the irrigation branch of the Canadian Government under particularly disadvantageous conditions in winter.

The gagings are made in the same manner as at open sections, except that the depth of the stream is taken as the distance from the bottom of the ice to the bed of the stream. The soundings, however, are always referred to the surface of the water in the holes. The vertical velocity curve method is usually used. The typical curve is said to differ from that obtained from an open-water observation in that it is drawn back more at the surface, which results in two points in the vertical near 0.2 and 0.8 of the total depth below the bottom of the ice at which the thread of mean velocity occurs under an ice cover. Both mean velocities at these two depths are said to give fairly accurate results.

The importance of chlorin determination for the superintendence and judgment of drinking water, F. MALMÉJAC (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 9, pp. 650-652; *abs. in Chem. Zentbl.*, 1914, I, No. 15, p. 1458; *Wasser u. Abwasser*, 8 (1914), No. 8, p. 481).—It is shown that the variation in chlorin content of drinking water is accompanied by corresponding variations of the organic content of animal origin and of the bacterial content. Fixed relations are, however, not established.

Preparing land with dynamite, C. D. WOODS (*Maine Sta. Bul.* 236 (1915), pp. 62, 63).—Experiments in progress since 1912 with a moderately heavy loam indicate that the use of dynamite for soil preparation, vertical drainage, and tree planting has not been in any way advantageous.

Silos and Silage, H. L. BLANCHARD (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 2, pp. 4-11, fig. 1).—General information regarding the construction and filling of the common types of silo is briefly given.

A movable hog house, W. HISLOP (*Washington Sta. Popular Bul.* 85 (1915), pp. 4, figs. 4).—This enumerates the essential features of an ideal hog house and illustrates and briefly describes the A-shaped house. A bill of material and estimate of cost of this house is given, the latter totaling \$11.17 on the basis of local retail prices at Pullman, Wash.

Homemade cow stall, H. L. BLANCHARD (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1913), No. 4, p. 16, figs. 2).—A homemade stall used by the author for about 20 years is briefly described. The distinctive features are a sliding feed box and a crosspiece which compels the cow to stand near the gutter, thus promoting cleanliness.

Trap nests and their use, V. R. MCBRIDE (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1914), No. 5, pp. 10-12, fig. 1).—The use of trap nests is briefly discussed and types installed at the station are illustrated and briefly described.

Lessons from the 1906 test fence, E. F. LADD and W. F. WASHBURN (*North Dakota Sta. Paint Bul.*, 1 (1915), No. 6, pp. 73-79, figs. 14).—This paper presents the deductions from the experiments with the so-called 1906 test fence described in a previous report (E. S. R., 20, p. 1089). A progress report of these experiments has also been noted (E. S. R., 30, p. 691).

Ochre was found to be unsatisfactory as a priming coat. The character of the lumber used influenced to a large extent the lasting quality of the paints, better results being obtained on soft pine than hard pine, western cedar, or fir. None of the mixed paints showed any superiority over the two single pigments used in the test.

“The indications are that it is far safer to use as a priming coat the same paint as is to be applied in the finishing coat, properly thinned with oil and turpentine, rather than to use ochre; and white lead (basic or sublimed) well thinned with pure linseed oil and turpentine has shown good quality and is well adapted as a priming coat. . . . Test fences properly constructed and with paint applied in accordance with the usual methods of practice, con-

stitute the most practical and satisfactory method which we have been able to devise for studying and testing the wearing qualities of paints. . . . The substitution of benzine for turpentine does not appear to give the same result as where turpentine as the thinner is employed in moderate quantities."

The experiments also indicate that repainting often brings out defects in the first painting not previously recognized. Sublimed lead was not found inferior in wearing quality to basic white lead.

Further experiments along this line are in progress.

North Dakota paint law and its benefits, E. F. LADD (*North Dakota Sta. Paint. Bul.*, 1 (1915), No. 6, pp. 80-85).—The general effect of the North Dakota paint law on the paint industry in the State is discussed. It is maintained that since its enactment there has been marked improvement in commercial paints, especially in the correct labeling of goods and the abolition of short-weight packages.

RURAL ECONOMICS.

The International Institute of Agriculture, its organization—its work—its results (*Rome: Internat. Inst. Agr.*, 1914, pp. 45, pls. 2, figs. 25).—This pamphlet gives the history and organization of the International Institute of Agriculture, the work it has undertaken to accomplish, and the results obtained.

See also a previous note (E. S. R., 30, p. 899).

The lure of the land, H. W. WILEY (*New York: The Century Co.*, 1915, pp. 368, pls. 31).—The author discusses some of the underlying motives affecting the movement of people from the rural districts to the city and the desire of city people to return to the country, and calls attention to the business side of farming as it is influenced by market conditions, the use of motive power, and the elimination of wastes. He briefly outlines the genesis of soils, theories regarding the causes governing its fertility, and the function of water in crop production. He also discusses the decreasing meat supply and the efforts of the Federal Government to improve agricultural production.

Wealth from the soil, C. C. BOWSFIELD (*Chicago: Forbes & Co.*, 1914, pp. 319).—This book is written as an aid to urban people who wish to become farmers or land owners.

Handbook on diversified farming (*Arkansas Sta. Circ.* 26 (1915), pp. 24, figs. 8).—This circular contains brief statements regarding the methods of growing various farm crops, planning a home vegetable garden, preserving fruits and vegetables, and raising live stock.

A method of analyzing the farm business, E. H. THOMSON and H. M. DIXON (*U. S. Dept. Agr., Farmers' Bul.* 661 (1915), pp. 26).—This publication furnishes an outline of a method and a blank form for analyzing the farm business to determine the investment, receipts, expenses, and labor income, and indicates how the form is to be used to determine the labor income, and how to measure the farm efficiency. The authors state that on a majority of farms, success is primarily dependent upon the size of the farm business, the yields of the crops, the returns per animal, and the diversity of the business. Those farms that are excellent in none of these respects almost universally fail.

The business side of farming, T. J. BROOKS (*Mississippi Agr. Col. Bul.*, 1914, June 20, pp. 48).—Suggested forms are given for organizing egg shipping associations, cooperative creameries, farmers' cooperative shipping associations, and cooperative marketing associations. A brief bibliography is appended.

Demurrage information for farmers, G. C. WHITE (*U. S. Dept. Agr. Bul.* 191 (1915), pp. 27).—This bulletin outlines the provisions of the uniform demurrage

code, makes a general survey of the state codes, and calls attention to their special features. The author considers that the greater part of the annual car shortage is due primarily to a lack of breadth of vision on the part of shippers, railroad officials, and legislators.

Farm accounts, C. S. ORWIN (*Cambridge: University Press, 1914, pp. 209*).—The author outlines the methods of making the farm valuations, types of records to be kept, forms to be used in the bookkeeping, and methods of closing the accounts and obtaining the profit and loss and the balance sheet.

Farm credit in Kansas, G. E. PUTNAM (*Amer. Econ. Rev., 5 (1915), No. 1, pp. 27-37*).—In 1914 a schedule of questions relating to rural credit was sent to representative bankers, merchants, and farmers in each of the 105 counties in Kansas. Among the conclusions drawn from the replies were that the cost of borrowing was from 1 to 2½ per cent higher than the rate recorded in the mortgage contract, and that practically all short-term loans were made on the fall settlement basis. If the farmer had no funds to make full payment his note was taken for the balance. There seems to be dissatisfaction with the interest rate in those counties where agricultural production is uncertain and land values speculative. The bankers indicated that the rate paid by farmers and merchants was practically the same, but that the rate was higher on city real estate than on farm mortgage loans. The author points out that several of the State laws have a tendency to make the lender's risk greater and thus force up the interest rate. The replies also indicated that farmers would not be willing to unite in a cooperative credit association.

Report of the Bureau of Marketing and Supplies of the Maine Department of Agriculture, C. E. EMBREE (*Rpt. Bur. Marketing and Supplies, Maine Dept. Agr. 1913, pp. 17*).—This report sets forth the work of the year. The bureau believes that the farmers, instead of shipping their produce through the farmers' union, should consign their products direct to their selling agents in the marketing centers, since this procedure places more responsibility upon the local organization and would more quickly bring about better business methods.

[Agricultural associations in Italy] (*Bol. Min. Agr., Indus. e Com. [Rome], Ser. B, 13 (1914), I, No. 5-6, pp. 175-222; II, No. 6, pp. 181-264*).—There are listed the name, location, type, date of organization, membership, and other facts for practically all the agricultural organizations in Italy.

The agricultural laborer in Belgium, B. BOUCHÉ (*Les Ouvriers Agricoles en Belgique. Brussels: Mich & Thron, 1913, pp. VIII+265*).—The author discusses the origin of paid agricultural workers, the types found, agencies for their distribution, contracts and agreements, and wages received, and suggests that there be an organization for their proper distribution, and that the agricultural laborer be represented on committees dealing with agricultural subjects.

The leasing of land in Belgium, E. VAN DIEVOET (*Le Bail a Ferme en Belgique. Louvain: C. Peeters, 1913, pp. VII+458, pls. 4*).—This book points out the relationship between the landowner and tenant, the length and termination of leases, and methods of recompensing the tenant for an increase in the value of the property.

Distribution of land according to crops and tenure (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intl., 6 (1915), No. 1, pp. 83-101, figs. 2*).—This article points out that in 1910 the total population of Bulgaria was 4,235,575, of which 3,108,816 were engaged in and dependent upon agriculture and 1,739,181 actively engaged. The total land devoted to agricultural purposes in 1908 was 7,982,450 hectares, of which 3,628,016 hectares were in fields, 2,834,493 in forests, 913,081 in pasture land, and 399,412 in meadows. Of the total, 4,625,787 hectares belonged to private persons and the remainder to the

State and other organizations. The total number of holdings was 942,897, of which 933,367 belonged to private persons. Forty-five per cent of the holdings contained 2 hectares or less, but 45 per cent of farm land is in holdings of between 5 and 15 hectares.

The agricultural outlook (*U. S. Dept. Agr., Farmers' Bul. 665 (1915), pp. 28*).—It is estimated that on March 1 there was about 21,000,000 bu. less surplus of wheat than a year previous. It appears that during the eight months ended March 1 the exports of wheat, including flour, amounted to 245,433,099 bu. as against 109,435,386 for a similar period for the year previous. The returns indicate that of the wheat produced in Minnesota and the Dakotas 43 per cent was Blue Stem, 21 per cent Velvet Chaff, 15 per cent Fife, and 12 per cent Durum.

The production of Hawaiian sugar is estimated at 612,000 short-tons for the 1914 campaign as against 546,524 for the 1913 campaign.

The first inquiry made as to the stocks of wool held by manufacturers on January 1 resulted in replies from manufacturers whose total purchases in 1914 amounted to 158,169,000 lbs. of wool (raw equivalent). Their stocks on January 1, 1915, amounted to 39,995,000 lbs., as compared with 22,933,000 lbs. on January 1, 1914.

It is stated that the average time of transit from the United States Pacific coast ports to England is about one-half what it was before the opening of the Panama Canal. Grain steamships previously averaged 94 days for this voyage while the average at present is 48.

The money wages of farm labor averaged during the past year about 1.7 per cent lower than in the preceding year, but about 9 per cent higher than 5 years ago. Information is given concerning the farm labor employment service of the U. S. Department of Labor, the countries prohibiting cereal exports, trend of prices of farm products, apples in cold storage March 1, etc. Statistical tables are given showing the stocks of cereals and aggregate value per acre of crop production for 1914-15 by States, the aggregate value per acre of crops by States for 1909-1914, and farm wages with and without board, by the month and by the day, and at harvest and other than harvest seasons. It also includes the usual data as to the prices of farm products.

Agricultural war-book (*Ottawa: Min. Agr., 1915, pp. 157, figs. 3*).—This book contains a series of articles describing the population, transportation, occupation of the people, and the agriculture of various countries with reference to conditions brought about by the present war.

[**Agriculture in Canada**], compiled by H. J. BOAM (In *Twentieth Century Impressions of Canada, London and Montreal: Sells Ltd., 1914, pp. 212-260, figs. 77*).—These pages are devoted to a description of the various agricultural organizations found in Canada by T. K. Doherty, the system of agricultural education by S. B. McCready, the experimental farms by O. C. White, the fruit industry by W. T. Macoun, the cattle industry by H. S. Arkell, dairying by J. A. Ruddick, the poultry industry by W. F. Moore, and swine raising by J. B. Spencer.

A pilgrimage of British farming, 1910-1912, A. D. HALL (*London: E. P. Dutton & Co., 1913, pp. XIII+452*).—The author describes the systems of farming observed during three summers' travel in the British Isles and treats of soils, cropping systems, methods of handling live stock, and the general drift of the agricultural practices in the communities visited

[**Agriculture in Denmark**] (*Statis. Aarbog Danmark, 19 (1914), pp. 26-29, 36-37, 44-54*).—These pages continue statistical information previously noted (*E. S. R., 30, p. 392*).

AGRICULTURAL EDUCATION.

Proceedings of the twenty-eighth annual convention of the Association of American Agricultural Colleges and Experiment Stations, edited by J. L. HILLS (*Proc. Assoc. Amer. Agr. Colls. and Expt. Stas.*, 28 (1914), pp. 272).—This is a detailed account of the proceedings, including reports of committees and papers submitted, of the convention held at Washington, D. C., November 11 to 13, 1914 (E. S. R., 32, p. 8).

Cooperative agricultural extension work (*U. S. Dept. Agr., Office Sec. Circ. 47* (1915), pp. 12).—This circular gives a brief explanation of the extension work now carried on in this country, discussing the cooperative agricultural extension act (E. S. R., 30, p. 601); organization of the extension work in the U. S. Department of Agriculture and the States; types of extension work—farm demonstrations, the county agent, boys and girls' club work, girls' demonstration work, home economics extension work, extension work through specialists, and movable schools; money available under the Smith-Lever Act, including a tabulated statement showing amounts available to the several States; and a list of Department and state officers in charge of extension work.

[The Smith-Lever Law and its probable operation in a number of the States] (*Quart. Alpha Zeta*, 13 (1914), No. 2, pp. 45, figs. 5).—This issue contains the text of the Smith-Lever Act and a series of articles by extension men and others interested in this work, giving an idea of the contemplated use of these funds in nearly all sections of the country.

Educational [work], R. H. FORBES (*Arizona Sta. Rpt. 1914*, pp. 373-378).—This is a progress report for the year on the regular and special agricultural courses and extension work of the Arizona College of Agriculture, including data as to attendance, etc.

[Instruction in home economics] (*Utah Agr. Col., Ext. Div. Circ.*, 2 (1914), Nos. 23, pp. 7, fig. 1; 41, pp. 4; 3 (1915), No. 5, pp. 4).—These circulars include Instructions in Organization of Home Economics Associations, by Gertrude M. McCheyne, Home Building Contest, and Program of Home Economics Associations, respectively.

[Agricultural and domestic science instruction in the high schools of Wisconsin] (In *Manual of the Free High Schools of Wisconsin*. Madison, Wis.: Democrat Printing Co., 1914, pp. 13-16, 71-92, 160-168, 178-180, 183, 184).—This manual outlines general requirements for securing special state aid for instruction in agriculture and home economics in high schools; the plan and method of work in agriculture, to be developed by means of suitable class-room instruction, observation and experiment work, field work, home projects, manual training projects related to the farm, community or extension work, including lists of apparatus and supplies, illustrative material, texts, and reference books; requirements for state aid for agriculture in the seventh and eighth grades; suggested courses of study in domestic art and science for Wisconsin grade and high schools, as outlined by a committee appointed by the Wisconsin Teachers' Association in 1910; methods of instruction, subject matter in sewing and cooking in the seventh and eighth grades, and in sewing, cooking, food study and dietaries, hygiene, and home management in the high school; and the state laws relating to state aid for agricultural and home economics instruction.

High school clubs in agriculture and home economics, C. L. ANDERSON and CLAIRE PARRISH (*Utah Agr. Col., Ext. Div. Circ.*, 2 (1914), No. 43, pp. 6).—This circular outlines the purpose and plan of these high school clubs, which have for their aim the study of industrial subjects and the development of a healthy community life.

Boys' and girls' demonstration club work in Arkansas, W. J. JERNIGAN (*Arkansas Sta. Circ.* 27 (1915), pp. 16).—This circular outlines the purpose and method of conducting and some of the results of the boys' and girls' corn, cotton, pig, canning, and poultry club work in Arkansas, as well as a tentative course for teachers in conducting club work in the schools.

School credit for home work, J. C. WERNER (*Kansas Agr. Col. Ext. [Pamphlet]*, 1914, pp. 7).—The author calls attention to the importance of home work and gives a suggestive list of subjects for credit for home work and a plan for allowing credit and reporting to teachers.

The Montana Country Life Education Association (*Bozeman, Mont.*, 1914, pp. 16).—This bulletin contains the proclamation of the governor of Montana setting apart October 9, 1914, as Rural Life Day, the constitution of the association, a model constitution and by-laws for local units, etc. A bibliography is added.

Agriculture, O. H. BENSON and G. H. BETTS (*Indianapolis: Bobbs-Merrill Co.*, 1915, pp. 9+444+16, figs. 183).—This elementary text combines practical and scientific information on the importance and value, geographical distribution, varieties, diseases and insect enemies, growing, harvesting, and storing of the principal farm and horticultural crops; the soil; the uses, value, distribution, judging and selecting breeds, feeding and care, and diseases of cattle, horses, swine, sheep, and poultry; farm and home management, the home grounds and wood lot, the county agricultural agent, farm implements and mechanics, road building and maintenance, and birds and other insect destroyers.

Practical helps in agriculture and nature study, E. S. JONES and H. L. FOWKES (*Taylorville, Ill.: Authors*, 1914, pp. 88).—This is intended as a supplementary book of practical information and scientific facts, rather than an outline or a manual, on cereals, legumes, soil, live stock, birds, the forest and ornamental trees, fungi, the potato, insects, farm machinery, composition of air, effects of heat upon bodies, siphons, collections and preservation of material for use in the study of agriculture, and school gardens and school yards. It includes type lessons, a number of bibliographies, score cards, and tables.

Outline of course in nature study and agriculture, D. R. WOOD (*Cal. Ed.*, 2 (1910), No. 3, pp. 143-205).—The author defines nature study, discusses its purpose, the training it gives, and the use of nature-study material, and outlines a course in nature study, through the seven grades, a course in the principles of agriculture, and a course in and directions for school-garden work. Types of nature-study lessons and experiments, an article on How to Find Material for Nature Study, by Mrs. L. C. Gay, and numerous bibliographies and references for teachers are included.

Nature study and agriculture for the rural schools of Texas, W. S. TAYLOR and C. H. WINKLER (*Bul. Univ. Tex.*, No. 361 (1914), pp. 73).—This is an outline of work in nature study for use in grades 1 to 6, inclusive, and of work in elementary agriculture for the seventh grade. A bibliography of reference books on nature study and agriculture for the rural schools is appended.

Nature study and agriculture in Manitoba schools (*Agr. Gaz. Canada*, 1 (1914), No. 11, pp. 932, 933).—An outline is given of the courses in school gardening and nature study in grades 1 to 8 of the elementary schools and in agriculture in grades 9 and 10 of the secondary schools.

Fights of the farmer, A. SNYDER (*Philadelphia and London: J. B. Lippincott Co.*, 1914, pp. XIV+234, pl. 1, figs. 115).—Instruction is given on fighting soil erosion, the loss of soil moisture and fertility, the wind, frost, weeds, injurious insects and animals, and farm waste. While intended primarily for the farmer, it can be utilized in nature study from an agricultural standpoint and for supplementary reading in the schools.

The book of useful plants, JULIA E. ROGERS (*Garden City, N. Y.: Doubleday, Page & Co., 1913, pp. XIV+374, pls. 31*).—This book, which is written for children, discusses the origin, geographical distribution, growth, and varieties of bread, forage, sugar, beverage, narcotic, and fiber plants, plants with edible seeds, leaves and stems, roots and tubers, and seed vessels, and plants that serve many or special purposes.

Correspondence courses in agriculture for teachers.—Course I, Farm plants and soils (*Off. Pub. Iowa State Col. Agr., 13 (1914), Nos. 21, pp. 23, figs. 3; 22, pp. 19, figs. 3; 13 (1915), Nos. 25, pp. 24, figs. 7; 27, pp. 21, figs. 5*).—Twenty lessons on farm plants and soils are presented in four assignments to show teachers what to teach and how the material can be best presented, and to furnish them a sufficient knowledge of agriculture to meet the requirements of the school law. Each lesson consists of a topical outline and exercises.

MISCELLANEOUS.

Twenty-fifth Annual Report of Arizona Station, 1914 (*Arizona Sta. Rpt. 1914, pp. 317-378, fig. 1*).—This contains the organization list, an administrative report by the director on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1914, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Twenty-seventh Annual Report of Colorado Station, 1914 (*Colorado Sta. Rpt. 1914, pp. 32*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, a report of the director on the work and publications of the station, and departmental reports.

Annual Report of Florida Station, 1914 (*Florida Sta. Rpt. 1914, pp. CVI+X, figs. 9*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, a list of the publications of the year, a general review of the work of the station during the year, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. Records of the dairy herd are also included.

Twenty-seventh Annual Report of Illinois Station, 1914 (*Illinois Sta. Rpt. 1914, pp. 13*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, brief notes as to the principal lines of work, and a list of the publications issued during the year.

Twenty-seventh Annual Report of Louisiana Stations, 1914 (*Louisiana Stas. Rpt. 1914, pp. 32*).—This contains the organization list, a report by the director discussing the work of the stations, an account of their progress, including brief departmental reports, and a financial statement as to the federal funds for the fiscal year ended June 30, 1914, and as to the state funds for the fiscal year ended November 30, 1914. The experimental work reported is for the most part abstracted on page 32 of this issue.

Finances, meteorology, index (*Maine Sta. Bul. 234, pp. 279-306+XVI*).—This contains the organization list of the station; meteorological observations noted on page 19; a financial statement for the fiscal year ended June 30, 1914; an index to Bulletins 223-234, which collectively constitute the thirtieth annual report of the station; a list of the publications of the year; announcements of the work, personnel, and equipment of the station; abstracts of papers published elsewhere, including Studies on the Physiology of Reproduction in the Domestic Fowl—VIII, On Some Physiological Effects of Ligation, Section, or Removal of the Oviduct (E. S. R., 32, p. 670); and IX, On the Effect of Corpus Luteum Substance Upon Ovulation in the Fowl (E. S. R., 32, p. 671);

Studies on Inbreeding—IV, On a General Formula for the Constitution of the Nth Generation of a Mendelian Population in which all Matings are of a Brother+Sister; and V, Inbreeding and Relationship Coefficients (E. S. R., 32, p. 665); On the Law Relating Milk Flow to Age in Dairy Cattle (E. S. R., 32, p. 575); The Immature Stages of the Tenthredinoidea (E. S. R., 31, p. 155); and A Note on *Rhagoletis pomonella* in Blueberries (E. S. R., 32, p. 350); and abstracts of several papers abstracted elsewhere in this issue.

Twenty-sixth Annual Report of Vermont Station, 1913 (*Vermont Sta. Rpt. 1913*, pp. XX+327, pls. 14, figs. 42).—This contains the organization list, a brief announcement concerning the station, a financial statement for the fiscal year ended June 30, 1913, a report of the director on the publications and work of the station, and reprints of Bulletins 168-174, previously noted.

Twenty-seventh Annual Report of Vermont Station, 1914 (*Vermont Sta. Rpt. 1914*, pp. XIX+394, pls. 39, figs. 17).—This contains data corresponding to the above for the fiscal year ended June 30, 1914, including reprints of Bulletins 175-183, previously noted.

Report of the Western Washington Experiment Station, April 1, 1913, to December 31, 1914, W. A. LINKLATER (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 2 (1915), No. 10, pp. 30, figs. 3).—This contains the report of the superintendent of this substation for the period indicated, including a financial statement and departmental reports. The experimental work recorded is for the cost part abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 1 (1913), Nos. 3, pp. 16, figs. 7; 4, pp. 16, figs. 10; 1 (1914), Nos. 5, pp. 16, figs. 5; 6, pp. 16, figs. 9; 7, pp. 16, figs. 4; 2 (1914), Nos. 1, pp. 16, figs. 3; 2, pp. 16, figs. 4; 3, pp. 16, figs. 5; 4, pp. 7, fig. 1; 5, pp. 12, fig. 1; 6, pp. 16, figs. 5; 7, pp. 12, fig. 1; 8, pp. 12, fig. 1; 9, pp. 16, figs. 4; 2 (1915), No. 12, pp. 16, figs. 6; 3 (1915), No. 4, pp. 16, figs. 5).—These numbers contain brief articles on the following subjects:

Vol. 1, No. 3.—The Balanced Ration, by H. L. Blanchard; Renewal of Old Orchards, by J. L. Stahl; Blossom End Rot of Tomatoes and Woolly Bear Caterpillars, by H. L. Rees; Feeding for Egg Production, by V. R. McBride; and Alfalfa in Western Washington and Sweet Clover, by B. Stookey.

Vol. 1, No. 4.—Standard Varieties of Tree Fruits, by J. L. Stahl (see p. 44); Fire Blight of Pear and Apple, by H. L. Rees (see p. 53); The Growing of Succulent Feeds for Fall and Winter Use—I, Root Crops, by E. B. Stookey (see p. 34); Poultry Diseases, by V. R. McBride; and Homemade Cow Stall, by H. L. Blanchard (see p. 90).

Vol. 1, No. 5.—Varieties of Strawberries and Raspberries, by J. L. Stahl (see p. 47); The Breeding Flock, by V. R. McBride; The Growing of Succulent Feeds for Fall and Winter Use—II, by E. B. Stookey (see p. 34); and Potato Blight and Identification of Plant Diseases, by H. L. Rees.

Vol. 1, No. 6.—Potato Growing in Western Washington, by J. L. Stahl (see p. 40); Means of Determining Soil Fertility, by E. B. Stookey; and Diseases of Potatoes, II, by H. L. Rees (see p. 52).

Vol. 1, No. 7.—What Dairy Farming Means, by H. L. Blanchard; Systems of Training Berry Canes, by J. L. Stahl (see p. 47); Drainage and Aeration, I, by E. B. Stookey; Mating and Line Breeding Poultry, by V. R. McBride (see p. 77); Selecting Eggs for Incubation, by V. R. McBride (see p. 77); Incubation, by V. R. McBride (see p. 77); and Diseases of Potatoes, III, by H. L. Rees (see p. 52).

Vol. 2, No. 1.—The Dairyman's Best Crop, by H. L. Blanchard; Soil Tillage, Part 2, by E. B. Stookey; Brooding Chicks, by V. R. McBride; Spraying Ma-

chinery and Accessories, by J. L. Stahl; and Spraying for Orchard Diseases and Insects, by H. L. Rees.

Vol. 2, No. 2.—Silos and Silage, by H. L. Blanchard (see p. 90); Hog Raising on Partially Cleared Land, by W. A. Linklater; Eradication of Lice and Mites, by V. R. McBride; and Feeding and Care of the Calf for the Dairy, by H. L. Blanchard.

Vol. 2, No. 3.—Concerning Moles, by T. H. Scheffer; Saving Hay Crops, by H. L. Blanchard (see p. 38); Harvesting the Berry Crops, by J. L. Stahl (see p. 47); Capons and Caponizing, by V. R. McBride; and Notes on Plant Diseases, and Some Vegetable Insects, by H. L. Rees.

Vol. 2, No. 4.—The Feed Supply in Dry Weather, and Grazing the Aftermath, by H. L. Blanchard; Summer Pruning, by J. L. Stahl; Producing Marketable Eggs, by V. R. McBride; Notes on Tomato Diseases, by H. L. Rees; and Late Sown Feed Crops, by E. B. Stookey.

Vol. 2, No. 5.—Agricultural Fairs; Fall Sowing of Hay and Pasture Mixtures, by E. B. Stookey; Trap Nests and Their Use, by V. R. McBride (see p. 90); and Hill Selection as a Preventive of Certain Potato Diseases, by H. L. Rees.

Vol. 2, No. 6.—Experimental Spraying for Blackberry Anthracnose, by H. L. Rees (see p. 54); Fall Sown Forage and Grain Crops, by E. B. Stookey; Late Summer Care of Poultry, by V. R. McBride; and Concerning Bee Culture, by J. W. Ware.

Vol. 2, No. 7.—Liming the Soil, by E. B. Stookey; Fertilizer Tests with Red Raspberries, by J. L. Stahl (see p. 48); Feeding Laying Hens, by V. R. McBride; and Keeping Out Fire Blight. Danger from Lead Arsenate Poisoning, and Apple Anthracnose or Black Spot Canker, by H. L. Rees.

Vol. 2, No. 8.—Soil Fertility Problems, by E. B. Stookey (see p. 33); The Double Deckerd Hive to Control Increase, by J. W. Ware; The Potato Crops, by J. L. Stahl; Potatoes as a Poultry Food, by V. R. McBride; Concerning Some Farming Failures, by H. L. Blanchard; and Poultry Diseases, by V. R. McBride.

Vol. 2, No. 9.—Factors Influencing the Quality of Milk for Condensing Purposes, by W. A. Linklater (see p. 79); Poultry House Construction, and The Colony Brooder, by V. R. McBride; The Succulent Feed Supply, by W. A. Linklater; Barnyard Manure is Worth Saving, by E. B. Stookey; What is the Foot-and-Mouth Disease, by W. Hislop; and the Winter School.

Vol. 2, No. 12.—The Root Maggot Pest, by E. B. Stookey (see p. 62); Incubation, by V. R. McBride; Spring and Summer Spraying for the Orchard, by H. L. Rees (see p. 47); and Rhubarb Culture, by J. L. Stahl (see p. 44).

Vol. 3, No. 1.—Dealing with the Mole, by T. H. Scheffer; Farm Butter Making, by H. L. Blanchard; Brooding and Feeding Chicks, by V. R. McBride; The Drone Bee Nuisance, by J. W. Ware; Concerning Hog Raising, by W. A. Linklater; and Control of Damping Off Fungi, by H. L. Rees.

NOTES.

Colorado College and Station.—Mrs. Agnes M. Riddle, of Denver, and H. D. Parker, of Greeley, have been elected to the governing board, vice F. E. Brooks and William Harrison.

A central heating plant has been authorized under a state appropriation of \$50,000 and construction will begin at once.

Hawaiian Sugar Planters' Station.—W. R. McAllep has been appointed assistant chemist.

Illinois University and Station.—The legislature has appropriated \$5,000,000 for the use of the institution for the current biennium. This is practically the full amount accumulated in the state treasury from the one mill tax voted four years ago for the support of the university.

Robert Stewart, professor of chemistry and chemist in the Utah College and Station, has been appointed associate professor of soil fertility and assistant chief in soil fertility in the station beginning September 1.

Oklahoma College and Station.—James W. Cantwell, superintendent of schools at Fort Worth, Tex., has been appointed president of the college. Under a recent act of the legislature providing for the appointment of members of the Board of Agriculture by the governor, the following four new members have been designated, who by virtue of their position become members of the board of regents of the agricultural college: R. H. McLish, Ardmore; Joe Alexander, Moffitt; C. B. Campbell, Minco; and J. J. Savage, Hollis.

Purdue University.—The first rural minister's conference was held at the university May 11-13, with an attendance of about 200 ministers and laymen.

Iowa College and Station.—*Science* notes that J. B. Davidson, professor of agricultural engineering and chief engineer, has been appointed to the newly established professorship of agricultural engineering at the University of California, and among other duties is to develop at Davis a testing plant for the study of the efficiency of farm machinery.

Maryland College.—Despite adverse weather conditions, the annual Farmers' Day, May 29, attracted an attendance of over 1,000. The speaker of the day was Hon. Carl Vrooman, Assistant Secretary of Agriculture, who spoke on The New Agriculture. He urged the fullest participation in the new system of demonstration work and the improvement of country life, not only along economic lines but also in the establishment of the cooperative spirit, the spirit of organization in every country neighborhood for the common good of all concerned.

Nebraska University and Station.—The legislature has granted the funds necessary to duplicate those accruing under the Smith-Lever Act and has authorized a one mill state tax for salaries and maintenance and a three-fourths mill tax for a building fund. Approximately \$1,320,000 will be available for land and buildings during the ensuing biennium. Plans have been completed for the new dairy building and nearly completed for the Bessey Natural Science building. An agricultural engineering building and a horse barn are also contemplated.

R. J. Pool has been appointed acting head of the department of botany, J. E. Weaver, formerly of the botanical department of the Washington College, has been appointed assistant professor of botany, and E. H. Hoppert assistant professor of horticulture in extension work.

Oregon College and Station.—R. M. Rutledge, secretary to the dean and director, has accepted a research fellowship at the University of Wisconsin in cooperation with this Department.

Weekly Forecasts by the Weather Bureau.—A system of special weekly weather forecasts during the crop season has recently been established by the Weather Bureau of this Department for the corn, wheat, and cotton growing regions. These forecasts are telegraphed every Tuesday to certain weather stations in each State and there printed and mailed to such weekly newspapers as express a desire to receive them. Arrangements are also made for telegraphic distribution where desired.

Agricultural Education and Research in Canada.—The Dominion of Canada has appropriated \$3,308,000 for agriculture for the year 1915-16, \$785,000 of which is for the maintenance of experiment farms, \$550,000 for the development of the live-stock industry, \$540,000 for the "health of animals," \$280,000 for exhibitions, \$275,000 for the administration and enforcement of the meat and canned-foods act, and \$200,000 for the encouragement of cold-storage warehouses.

The appropriation includes \$150,000 for the development of the dairying industries and the improvement in transportation, sale, and trade of food and other agricultural products, \$140,000 to enforce the seed act, \$113,000 for the Fruit Branch, \$100,000 for the administration and enforcement of the destructive insect and pest act, \$25,000 for the administration and carrying out of the provisions of the agricultural-instruction act, \$25,000 for the National Biological Laboratory, \$20,000 to assist in the maintenance of the International Institute of Agriculture, \$20,000 for entomology, \$15,000 for publications, and \$70,000 for exhibits, repairs, etc. A further \$900,000 is allotted under the agricultural-instruction act.

The new building at the Ontario Veterinary College is now in use. It is a five-story brick structure with 134-foot frontage and 900,000 cu. ft. capacity, and cost about \$250,000. It contains several large laboratories, an assembly room seating 500, an infirmary for horses, offices, etc.

At the Nova Scotia Agricultural College, a new science building 130 by 50 feet, with laboratories for chemistry, soil physics, entomology, plant diseases, and home economics, an assembly hall seating 250, offices, classrooms, etc., is nearing completion. J. A. Sinclair has succeeded J. Standish in the veterinary department, and C. A. Good has been appointed assistant entomologist.

F. L. Drayton has been appointed assistant botanist at the Canadian Experimental Farms and George W. Muir assistant animal husbandman.

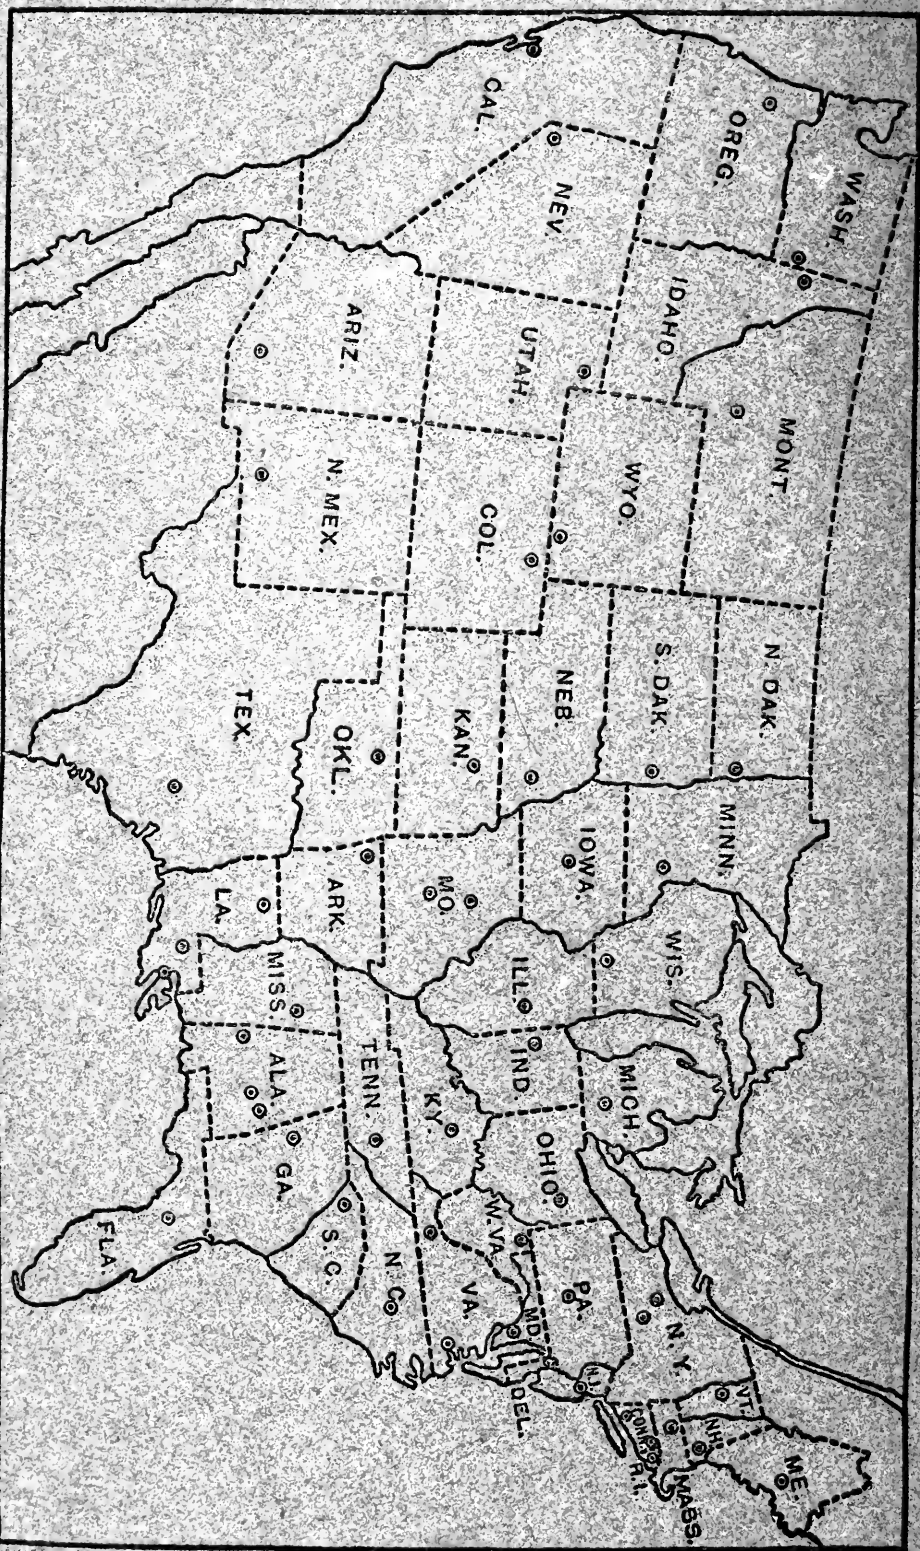

In a one-acre turnip-growing contest in three counties of Nova Scotia, participated in by 30 farm boys between the ages of 15 and 20 years, the yields of the first prize winners in Cumberland County were 1,296 bu., in Colchester County 1,266 bu., and in Pictou County 1,245 bu. Four prizes of \$75, \$50, \$30, and \$20 were given in each county. The average yield of field roots in Canada, according to the Canada Yearbook, is about 360 bu. per acre.

Journal of the Association of Official Agricultural Chemists.—In accordance with the decision of the association at its 1914 meeting, the *Journal of the Association of Official Agricultural Chemists* is to be established. This will be issued quarterly and will consist of the proceedings, official and provisional methods of analysis, and reports of investigations of value to food, drug, and feed control chemists which are not available for publication elsewhere. The first number is expected to be ready for distribution in July and will contain the 1913 proceedings.

CONTENTS OF VOL. XXXIII, NO. 2.

Editorial notes:	
Progress in the organization of agricultural extension work under the Smith-Lever Act.....	Page. 101
Some administrative problems being encountered.....	102
Recent work in agricultural science.....	107
Notes.....	197

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Organic constituents of Pacific coast kelps, Hoagland.....	107
The theory of alkalimetric and acidimetric titrations, Bjerrum.....	109
The Gunning-copper <i>v.</i> the Kjeldahl-Gunning-Arnold method, Jensen.....	109
Cleaning soils for microscopic examination, Fry and Cullen.....	109
The gravimetric determination of phosphoric acid in soils, Brauer.....	110
Estimation of citric acid-soluble phosphoric acid in Thomas slag, Neubauer....	110
Estimation of water-soluble phosphoric acid in superphosphate, Neubauer.....	110
About the titrametric estimation of cyanamid, Grube and Krüger.....	110
Examination, sampling, and guaranty of fertilizing lime, Neubauer.....	110
Blood charcoal as a purifying agent for arsenic solutions, Chapin.....	110
A substitute for potassium permanganate to liberate formaldehyde gas, Dixon..	111
Improved method for inorganic phosphoric acid, Chapin and Powick.....	111
Determination of decomposition in eggs, etc., Houghton and Weber.....	112
Specific gravity and percentage of fat and total solids in milk, Fleischmann..	112
Morres' alizarol test for testing keeping quality of milk, Devarda and Weich..	112
What value has the alizarol test as a control of the milk supply? Devarda..	112
The alcohol and alizarol tests, Morres.....	112
Titration of milk with alcohol of various concentrations, Löhnis.....	113

	Page.
The alcohol test in relation to milk, Ayers and Johnson, Jr.....	113
The value of the rosolic acid-alcohol test, Bahr.....	115
Kellner's modification of Petermann's method, Loges.....	115
A study in drying urine for chemical analysis, Braman.....	116
Quantitative estimation of urea and allantoin in urine, Plimmer and Skelton..	116
A permanent preparation of urease and its use, Van Slyke and Cullen.....	116

METEOROLOGY.

Relation of climate to plant growth in Maryland, McLean.....	116
A correlation of weather conditions and production of cotton in Texas, Kincer..	117
Temperature and spring wheat in the Dakotas, Blair.....	117
The distribution of the rainfall in the eastern United States, Wallis.....	117
Monthly Weather Review.....	117
Meteorological observations at Massachusetts Station, Ostrander and McLain..	118
Instructions for cooperative observers.....	118

SOILS—FERTILIZERS.

Colloid chemistry in the study of soils, Gedroïts.....	118
The destructive distillation of soil, Holmyard.....	120
Electrolytic determination of the biological solution of soil, Pantanelli.....	120
Contribution to bacteriological studies of the soil, Wojtkiewicz.....	120
Isolation of <i>Bacillus radicicola</i> from soil, Lipman and Fowler.....	121
Origin of the "niter spots" in certain western soils, Stewart and Peterson....	121
The soils of the western New York fruit and grain region, Fippin.....	121
The sandy soil of Sylvan Beach, New York, Knight.....	121
Salts in soils and waters of the south coast of Porto Rico, Crawley.....	121
Application of fertilizers to soil, and losses by leaching, Crawley and Cady.....	122
Effect of fertilizers on physical properties of Hawaiian soils, McGeorge.....	122
Influence of radio-active earth on plant growth and crop production, Rusby..	123
Radio-active ores and plant life, Bastin.....	123
The significance of certain food substances for plant growth, Bottomley.....	124
The question of fertilizers, Rebello da Silva.....	124
Utilization of the sewage of New York City, Soper et al.....	124
The mechanism of nitrification, Mumford.....	124
Synthesis of the oxids of nitrogen by the electric arc, Roselier.....	125
When should lime nitrogen be applied to winter grains? Wagner.....	125
Nitrogenous fertilizers from refuse substances, Elschner.....	125
Availability of the nitrogen in Pacific coast kelps, Stewart.....	125
The bone, animal waste, phosphate, and phosphorus industries, Vézien.....	126
Analyses of commercial fertilizers, Peck, Sample, and Garrison.....	126
Commercial fertilizers, Hite and Kunst.....	126

AGRICULTURAL BOTANY.

On certain relations between the plant and its physical environment, Farmer..	126
The plant in relation to its biological environment, Farmer.....	126
Town smoke and plant growth, Crowther and Ruston.....	126
Damage to vegetation by sulphurous and sulphuric acids, Tatlock and Thomson..	127
Hail injury to cereals, Schander.....	127
Transpiration and the ascent of sap in plants, Dixon.....	127
Extreme alterations of permeability without injury, Osterhout.....	127
The problem of food movement in trees, Elliott.....	127
Influence of chlorids and nitrates on germination, Micheels.....	128
A method of prophesying the life duration of seeds, Crocker and Groves.....	128
Light and the rate of growth in plants, MacDougal.....	128
Relation between brief illumination and reaction in vetches, Campanile.....	129
The identity of heliotropism in animals and plants, Loeb and Wasteneys.....	129
The coefficient of mutation in <i>Oenothera biennis</i> , DeVries.....	129
An interpretation of self-sterility, East.....	129
Number of ovules formed and seeds developing in <i>Cercis</i> , Harris.....	130
Taxonomic value of pore characters in grass and sedge rusts, Arthur and Fromme..	130
The development of <i>Armillaria mellea</i> , Atkinson.....	130

FIELD CROPS.

	Page.
Report on experimental work of the Palur station for 1913-14, Mehta.....	130
A handbook of Nebraska grasses, Wilcox, Link, and Pool.....	131
The Spanish grasses of northern Africa, Manetti.....	131
Agave.—Its culture and exploitation, Michotte.....	131
First series of researches with reference to red clover breeding, Gmelin.....	131
Genetic and cytological study of certain types of albinism in maize, Miles.....	131
Perjurate cotton hybrids, Marshall.....	132
Relation of density of stand and yield in cotton, Shreder.....	133
Close planting of cotton to avoid frost injuries, Shreder.....	133
Flax culture, Freeman.....	133
Germination of hemp seed, Consolani.....	133
Experiments on lime requirements of lupines, von Seelhorst et al.....	133
Yields of native prickly pear in southern Texas, Griffiths.....	134
Report of the prickly pear traveling commission, Johnston and Tryon.....	134
On the inbreeding of rye, von Rümker and Leidner.....	134
Physiological studies of <i>Bacillus radicola</i> of soy bean, Wilson.....	134
Can sodium replace potash as a nutrient for sugar beets? Krüger.....	135
Loss in tonnage of sugar beets by drying, Shaw.....	135
Variation in content of sugar in beets during second year, Munerati et al.....	135
Contribution on the biology and valuation of beet seeds, Plaut.....	135
Results in breeding and selection of sugar cane at Sempalwadak, Java, Quintus.....	136
The structure of the stomata of the sugar cane, Kuyper.....	136
Sugar cane, its cultivation and gul manufacture, Knight.....	136
Conservation of soil moisture in the cane fields, Crawley and Cady.....	136
Stripping of cane, Crawley.....	136
Using cane tops for planting, Rosenfeld.....	136
Tobacco mutations, Hayes.....	137
Tobacco breeding in Dalmatia, Preissecker.....	137
Report of cultural and variety tests with wheat, Nelson and Osborn.....	137
Spring wheat in the Great Plains: Relation of cultural methods, Chilcott et al.....	137
Tillering of spring wheat, Vorobev.....	138
Pure seed law, Cooper.....	138
Pure seed law.....	138
Weed seeds in farm lands, Fryer.....	138
The destruction of weeds by the use of sulphuric acid, Rabaté.....	139
Weeds: How to control them, Cox.....	139

HORTICULTURE.

Experiments in growing greenhouse crops on muck or humus soils, Thompson ..	139
Grafting the eggplant on <i>Solanum torbum</i> , Van Hermann.....	139
Tomatoes for North Dakota, Werner.....	140
The pollination and fertilization of fruit trees, Pescott.....	140
Fruits for Minnesota planting.....	140
An orchard survey of Jefferson County, Jeffries.....	140
Fire pots as a protection against frost, Davis.....	141
Some common spray mixtures, Watkins.....	141
Cost of distributing, Powell.....	141
[Papain extraction experiments], Watts.....	141
Strawberry growing in Arkansas, Wicks.....	142
Strawberry varieties, Taylor.....	142
Strawberry supply and distribution in 1914, Sherman, Walker, and Schlessner.....	142
Grape culture, with special reference to eastern Oregon, Allen.....	142
Pruning and training young vines, Ravaz.....	142
Preventable causes of grape loss, Bioletti.....	143
The partridge berry (<i>Vaccinium vitis-idaea</i>), Torrey.....	143
Some recent literature on nuts and nut growing.....	143
Preliminary report on the Persian walnut, Deming.....	143
Conifers: Their usages, plantings, and enemies, Kelly.....	143
Tree planting in streets, Farmer.....	143
The amateur garden, Cable.....	143
Orchid cultivation and its bearing upon evolutionary theories, Costantin.....	143

FORESTRY.

	Page.
The variation in length of coniferous fibers, Shepard and Bailey.....	143
Seed production of western white pine, Zon.....	144
Ash in North Carolina, Sterrett.....	144
The forests of Chile, Albert.....	144
Fifth biennial report of state forester of California, Homans.....	144
[Report on Indiana Forest Reserve for 1914].....	144
Eleventh annual report of the state forester of Massachusetts, Rane.....	144
Forest fires in North Carolina and prevention in United States, Holmes.....	144
Report on forest administration in Bihar and Orissa, Carter.....	145
Forestry in the British Empire, Schlich.....	145

DISEASES OF PLANTS.

Fungus diseases of plants and their treatment, Farquharson.....	145
Spore formation in rusts, particularly <i>Puccinia malvacearum</i> , Blaringhem.....	145
Some Scottish rust fungi, Wilson.....	145
Ustilago, Potebnia.....	145
On the propagation of rust in cereals in Sweden and France, Blaringhem.....	145
Report on barley diseases, 1913, Appl.....	146
Corn stalk and corn root diseases in Iowa, Pammel, King, and Seal.....	146
Downy mildew of the cucumber, Jehle.....	146
Bacterial ring rot of potato, Spieckermann and Kotthoff.....	146
Powdery scab of the potato, Sands.....	146
Field studies of the crown gall of sugar beets, Townsend.....	147
Potato and tomato diseases, Molinas.....	147
Wart disease of potatoes, Cuthbertson.....	147
<i>Phoma destructiva</i> , the cause of a fruit rot of the tomato, Jamieson.....	147
Blue mold in tobacco, Smith.....	147
A bacterial disease of fruit blossom, Barker and Grove.....	148
Infection and immunity studies on the apple and pear scab fungi, Wiltshire.....	148
Wind scorch of apple foliage, Barker and Gimingham.....	148
Sources of the early infections of apple bitter rot, Roberts.....	148
The natural modes of distribution of pear blight in California, Jones.....	149
Black rot in Spain, Ravaz.....	149
Fungus and other diseases of citrus trees, Darnell-Smith and MacKinnon.....	149
<i>Pseudomonas citri</i> , the cause of citrus canker, Hasse.....	149
Citrus canker in Florida and the Gulf States, Fawcett.....	149
The citrus canker situation in Florida, Tenny.....	149
Fungus diseases of limes, Rorer.....	150
The cause of rotting of oranges from Brazil, Rushton.....	150
A remedy for the coconut bud rot, Johnson.....	150
Observations on <i>Rhizina inflata</i> , Weir.....	150
A new disease of plantation rubber in Malaya, Brooks.....	150
Pink disease, Brooks and Sharples.....	151
A study on a "mottled" disease of the black wattle, van der Byl.....	151
Control of dry rot, Moormann.....	151
The dry rot question, Falck.....	151
Internal therapy of plants, Dement'ev.....	151
Investigations on Bordeaux mixtures, Barker and Gimingham.....	151
Burgundy mixture, Fonzes-Diacon.....	152

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Economic zoology report for the year 1913, Aders.....	152
A pocket list of the mammals of eastern Massachusetts, Brown.....	152
The pocket gopher of the boreal zone on San Jacinto Peak, Grinnell and Swarth.....	152
Food habits of the skunk, Pellett.....	152
The value of birds to man, Buckland.....	152
Birds that destroy grapes, Butler.....	152
Species which have reared young and hybrids bred in captivity, Page.....	152
Insects: Their life histories and habits, Bastin.....	153
Injurious insects, Neal.....	153
Report of the Kansas State Entomological Commission for 1913 and 1914.....	153
Report of the entomological department of Rhode Island, 1913, Stene et al.....	153
Report of the entomologist, Patterson.....	153

	Page.
Insect pests of Nigeria, Lamborn.....	153
The agricultural pests of the southern Provinces, Nigeria, Lamborn.....	153
Pests of cotton in Fergana, according to observations in 1913, Vassiliew.....	153
Report of the entomologist and vegetable pathologist, Tryon.....	153
Insect pests of coconuts.....	154
Insects affecting the lime, Ulrich.....	154
In regard to the poisoning of trees by potassic cyanid, Sanford.....	154
Homemade lime-sulphur concentrate, Scott.....	154
Concerning some medico-entomological problems, Martini.....	154
Effect of <i>Coccobacillus acridiorum</i> on <i>Pachytylus migratorius</i> , Borodin.....	154
<i>Nysius senecionis</i> as an enemy of newly planted vines, Picard.....	154
The sugar cane scale (<i>Chionaspis tegalensis</i>) and its control, Van der Goot.....	155
The gipsy moth in the Crimea, Shtchegolev.....	155
The apple-tree tent caterpillar, Quaintance.....	155
A new cotton-seed moth (<i>Mometa zemíodes</i>) from West Africa, Durrant.....	155
The fight against <i>Cydia pomonella</i> and <i>C. funebrana</i> , Kostarev.....	155
<i>Cydia funebrana</i> , its bionomics and methods of fighting it, Kostrovsky.....	155
Artificial infestation of <i>Agrotis segetum</i> with Hymenoptera, Pospelow.....	155
The Hessian fly, Webster.....	155
The sorghum midge in Tucumán, Rosenfeld and Barber.....	155
Prophylaxis of malaria with special reference to the military service, Craig.....	155
Mosquito-borne diseases.....	156
The lesions produced by the bite of the "black fly," Stokes.....	156
Proposal of new muscoid genera for old species, Townsend.....	156
A maggot trap in practical use, Hutchison.....	156
Observations on blow flies, Whiting.....	157
A tachinid parasite with an intracuticular stage, Thompson.....	157
Sarcophagidæ of New England: Males of <i>Ravinia</i> and <i>Boettcheria</i> , Parker.....	157
Appearance of the Colorado potato beetle in Germany.....	158
The rose beetle and the injury it causes in the Samoan Islands, Friederichs.....	158
A trap for turnip fly, Lefroy.....	158
The cotton and corn wireworm (<i>Horistonotus uhlerii</i>), Conradi and Eagerton.....	158
Life history notes on the plum curculio in Iowa, Webster.....	159
Four new injurious weevils from Africa, Marshall.....	159
Results of cooperative experiments in apiculture, Pettit.....	159
Inheritance in the honeybee, Newell.....	159
A new species of <i>Habrobracon</i> sp., parasitizing <i>Chloridea obsoleta</i> , Bogoljubov.....	159
Acari found on rodents frequenting human habitations in Egypt, Hirst.....	159
The rat trypanosome in its relation to the rat flea, Minchin and Thomson.....	159

FOODS—HUMAN NUTRITION.

Kansas flours—chemical, baking, and storage tests, Swanson et al.....	160
[Wheat and flour analysis].....	161
Bleached flour, Haley.....	162
The alcohol-soluble proteins of wheat and rye, Gróh and Friedl.....	162
The physical chemistry of bread, Lorenz.....	162
German agricultural breads, Parow.....	162
War bread, Strube.....	162
The use of potatoes in bread making, Neumann and Fornet.....	162
Composition of <i>Euchlæna mexicana</i> , Pieraerts.....	162
Nutritive value of frozen meat, Valenti.....	162
Utilization of pork in provisioning the army, Girard.....	163
The toxicity of some ducks' eggs, Carles.....	163
Influence of fat content of milk on rate of digestion, Kreidl and Lenk.....	163
The nutritive value of boiled skim milk, Klein.....	163
Cow's milk and vegetable milk; difference in gastric digestion, Fischer.....	163
The reaction of cow's milk modified for infant feeding, Clark.....	163
Comparative nutrient value of cod liver oil and cordials, Street.....	163
The mineral constituents of honey, Kapeller and Gottfried.....	164
Tomato conserves, Carles.....	164
Observations on mango rash, Concepción.....	164
The organic flavoring compounds, Cohn.....	164
[Inspection and analyses of foods, drugs, and stock feeds], McRae et al.....	164
[Food inspection], Barney.....	164
Annual report of the food and drug commissioner [of Missouri], Fricke.....	164

	Page.
[Food and drug inspection], Allen.....	164
Eleventh report of the food commissioner of North Dakota, Ladd et al.....	164
Twenty-eighth annual report of the dairy and food division, Strode.....	164
Ninth biennial report of the dairy and food commissioner of Utah, Hansen....	165
Adulteration of food, McGill.....	165
Laws relating to hotels, restaurants, etc., and inspection thereof.....	165
[Inspection of canneries], Bingham.....	165
Anglo-American cooking, Central-American cooking, Goy.....	165
California Mexican-Spanish cookbook, Haffner-Ginger.....	165
Army rations.....	165
Army ration during war time, Gautier.....	165
The French Army ration in time of war, Gautier.....	165
Review of meat prices in Germany during the past 400 years, Badermann.....	165
[The cost of living in Australia], Knibbs.....	166
Cost of living in Australia, Knibbs.....	166
Feeding the masses, Kranold.....	166
Influence of protein consumption on muscular work, Testa and Sormani.....	166
Studies of the origin of cholesterolin, Dezani and Cattoretti.....	166
Absorption of fat and lipoids, London and Wersilowa.....	166
Physiological properties of lipins of egg yolk, McCollum and Davis.....	166
Lecithids contained in cod liver oil, Iscovesco.....	166
The phosphorus content of the animal organism, Heubner.....	167
The phosphotungstate precipitate from rice polishings, Drummond and Funk..	167
Experimental polyneuritis in birds as compared with human beri-beri, Tasawa.	167
Transactions of the National Association for the Study of Pellagra.....	167
The presence of toxic bodies in expired air, Farmacbidis.....	167
An automatic balance for use in metabolism experiments, Abderhalden.....	167
[Report of the] nutrition laboratory, Benedict.....	167

ANIMAL PRODUCTION.

Annual review of investigations in general biology, compiled by Delage.....	167
Handbook of comparative physiology, edited by Winterstein.....	168
Review of experimental breeding investigations in zoology since 1900, Lang...	168
German zootechny.....	168
Sex determination and sex control in guinea pigs, Papanicolaou.....	168
A new era in the science of nutrition, Kahn.....	169
A chemical study of two drought-resisting forage plants, Lomanitz.....	169
Feeding sugar beet tops, Redlich.....	169
Fish meal as a feedstuff.....	169
Feeding experiments with lupine and horse chestnut flakes, Reisch et al.	170
Food for animals and process for the manufacture of the same.....	170
Feeding stuffs, Loges.....	170
[State feeding stuff laws], compiled by Brown.....	170
Feeding of cattle, Lima.....	170
Wintering store cattle.....	170
The weight of calves, Stewart.....	171
Rye and blue grass pastures for ewes suckling lambs, Hackedorn.....	171
Studies on methods of wool sorting, Kereszturi.....	171
Goats and their ancestors, Boutan.....	171
Swine-feeding experiments with chick-peas, Schmidt.....	171
Influence of meat and bone meal feeding on the bony framework, Gjaldbæk...	171
The swine industry in New York State.....	172
Prairie farmer's hog book, Gregory.....	172
Horse breeding in relation to national requirements, Pease.....	172
Horses, Lima.....	172
Retention of amino acids in metabolism of the fowl, Szalagyi and Kriwuscha..	172
Correlation between egg-laying and yellow pigment, Blakeslee and Warner.	172
Fancy points <i>v.</i> utility, Balkeslee.....	172
Method of selecting the high-producing hens, Kent.....	173
California poultry practice, Swaysgood.....	173
A poultry survey of Jackson County, Jacoby.....	173
Profitable squab breeding, Dare.....	173
Breeding for horns, Meyer.....	173
Rabbit culture and standard, Roth and Cornman.....	174

DAIRY FARMING—DAIRYING.

	Page.
Cattle feeding experiments in Denmark, Annett.....	174
Feeding experiments in Denmark with dairy cattle, Helms.....	174
Some results from the fattening of dairy cows, Hutchinson.....	175
The development of the dairy industry in Hungary, Kœrfer.....	175
The hygienic importance of acid-rennet bacteria in the udder of cows, Gorini..	175
The nature of the cellular elements present in milk, Hewlett and Revis.....	175
The yellow color in cream and butter, Palmer.....	175
Butter prices, from producer to consumer, Clark.....	175
Studies on the manufacture of cheese, 1913, 1914, Gorini.....	175
The manufacture of cheese from "heated" milk, II, Benson.....	175
The manufacture of condensed milk, milk powders, casein, etc., Mohan.....	176

VETERINARY MEDICINE.

Collected papers from the Research Laboratory, Detroit, Michigan.....	176
Castration of domesticated animals, Schoenleber and Dykstra.....	176
Chemical studies upon the genus <i>Zygadenus</i> , Alsborg.....	177
<i>Zygadenus</i> , or death camas, Marsh, Clawson, and Marsh.....	177
The examination of milk by the practicing veterinarian, Glage.....	177
Action of nucleinate of sodium on blood and milk, Doyon and Sarvonat.....	177
The nature of the opsonic substances of normal sera, Zinsser and Cary.....	178
The propagation of bacteria, spirilla, and spirochetes, Meirowsky et al.....	178
Methods for the disinfection of hides infected with anthrax spores, Tilley.....	178
The susceptibility of animals to infectious bulbar paralysis, von Ratz.....	179
Curative experiments with salvarsan in infectious bulbar paralysis, Hutyra...	179
Foot-and-mouth disease, Connaway and Luckey.....	179
Virus carriers as factors in foot-and-mouth disease, Mohler and Eichhorn.....	179
Hay as a carrier of the virus of foot-and-mouth disease.....	179
Transmission of foot-and-mouth disease to a dog, Martin.....	180
Mastitis complicating foot-and-mouth disease, Ramella.....	180
Remarks on the serodiagnosis of glanders, Pfeiler, Weber, and Schömmmer.....	180
Utility of the conglutination method for serodiagnosis of glanders, Waldmann..	180
John's disease, Sheather.....	180
The diagnosis of rabies, Michin.....	180
Experiments on the cultivation of rinderpest virus, Boynton.....	180
Aberhaldden's dialysis method in pulmonary tuberculosis, Wolf and Frank...	181
Studies on blood serum of cows immunized against tuberculosis, Baldwin.....	181
Occurrence of nongas-producing bacilli in paracolon bacillosis, Christiansen...	182
What is hog cholera? Schern and Stange.....	182
The hog cholera problem, Schern and Stange.....	182
Hog cholera and its suppression in North America, Schern.....	182
Preventive measures other than vaccination in combating hog cholera, Mayo..	182
Inoculation against swine fever, Hutyra.....	183
The paratyphoid bacilli of abortion in mares, Van Heelsberger.....	183
A reinvestigation of Konew's protective vaccination, Thienel and Jäger.....	183

RURAL ENGINEERING.

The flow of water in irrigation channels, Scobey.....	183
Ground water for irrigation in the Sacramento Valley, California, Bryan.....	186
Ground-water resources of Niles cone and adjacent areas, California, Clark....	187
Gazetteer of surface waters of Iowa, Hoyt and Ryan.....	187
Surface water supply of Ohio River basin for 1913, Horton et al.....	187
Surface water supply of St. Lawrence River basin, 1913.....	187
The utilization of the subterranean reservoir of Egypt, Mosseri.....	188
The value of large zinc pipes for carrying water, Rinck.....	188
Note on the bacteriotoxic action of water, Greig-Smith.....	188
Watering devices for moorland pastures, von Schmeling.....	188
The drainage of Jefferson County, Texas, Kipp, Hall, and Frescoln.....	188
Road building in swamps, Krüger.....	189
Machinery for construction and maintenance, Agg.....	189
Motor vehicle registrations and revenues, 1914.....	189
Trial of machine plowing in rice fields, Tarchetti.....	190
Manila rope fastenings.....	190

RURAL ECONOMICS.

	Page.
Rural social problems, Galpin.....	190
Country life week.....	190
The church at the center, Wilson.....	190
The making of a country parish, Mills.....	190
Working and living conditions of women employed in agriculture, Seufert et al..	190
Report on home industries in the highlands and islands.....	190
Abandoned farms for sale in Pennsylvania, Critchfield and Wible.....	191
International annual of agricultural legislation.....	191
Rural credits in Ireland, Frost.....	191
Long time farm loans, Hare.....	191
Cotton warehouses: Storage facilities now available in the South, Nixon.....	191
A system of accounting for cooperative fruit associations, Nahstoll and Kerr...	191
A system of accounts for farmers' cooperative elevators, Humphrey and Kerr..	192
The agricultural outlook.....	192
Fifth census of Canada, 1911.—Agriculture.....	193
Report of the department of agriculture of Norway for 1914.....	193
[Statistics of agriculture in Switzerland].....	193
[Agricultural statistics of Russia].....	193
[Agriculture in the Commonwealth of Australia], Knibbs.....	193
Some impressions of agriculture in Australia, Hall.....	193
[Agriculture in New Zealand], Fraser.....	193

AGRICULTURAL EDUCATION.

[Statistics of] agricultural and mechanical colleges.....	193
Duplication in separate agricultural colleges and state universities, MacBride..	194
Rural education, Potts.....	194
Report of an agricultural tour in Europe, America, and Japan, Coleman.....	194
Department of rural and agricultural education.....	194
The use of land in teaching agriculture in secondary schools, Merritt.....	195
Suggestions and requirements for teaching agriculture in graded schools, Cary..	195
Agricultural course for rural high schools.....	195
Corn and its uses.....	196
Agricultural competition for boys and girls in New York State, Tuttle.....	196
How to organize a club and keep up interest, Newbill.....	196

MISCELLANEOUS.

Twenty-sixth Annual Report of Georgia Station, 1913.....	196
Twenty-seventh Annual Report of Georgia Station, 1914.....	196
Twenty-fifth Annual Report of North Dakota Station, 1914.....	196
Java and the Philippines, Copeland.....	196

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	Page.	<i>U. S. Department of Agriculture—Con.</i>	Page.
Arkansas Station:			
Bul. 121, Jan., 1915.....	137	Bul. 193, The Drainage of Jefferson	
Bul. 122, Feb., 1915.....	142	County, Tex., H. A. Kipp,	
Georgia Station:		A. G. Hall, and S. W. Frescoln..	188
Twenty-sixth An. Rpt., 1913..	196	Bul. 194, The Flow of Water in	
Twenty-seventh An. Rpt.,		Irrigation Channels, F. C. Scobey..	183
1914.....	196	Bul. 197, Homemade Lime-sul-	
Hawaii Station:		phur Concentrate, E. W. Scott..	154
Bul. 38, Apr. 24, 1915.....	122	Bul. 199, Loss in Tonnage of Sugar	
Illinois Station:		Beets by Drying, H. B. Shaw...	135
Circ. 160, 2. ed., rev., Apr.,		Bul. 200, A Maggot Trap in Prac-	
1913; 3. ed., rev., Mar., 1915.	141	tical Use; An Experiment in	
Iowa Station:		House-fly Control, R. H. Hutch-	
Circ. 21, Mar., 1915.....	146	ison.....	156
Circ. 22, Mar., 1915.....	155	Bul. 202, The Alcohol Test in Rela-	
Kansas Station:		tion to Milk, S. H. Ayers, and	
Bul. 202, Jan., 1915.....	160	W. T. Johnson, jr.....	113
Massachusetts Station:		Bul. 203, Field Studies of the	
Met. Buls. 315-316, Mar.-		Crown Gall of Sugar Beets, C. O.	
Apr., 1915.....	118	Townsend.....	147
Missouri Station:		Bul. 208, Yields of Native Prickly	
Circ. 73, Mar., 1915.....	171	Pear in Southern Texas, D.	
Circ. 74, Apr., 1915.....	175	Griffiths.....	134
Nebraska Station:		Bul. 210, Seed Production of West-	
Bul. 148, Apr. 1, 1915.....	131	ern White Pine, R. Zon.....	144
New York State Station:		Bul. 213, The Use of Land in	
Bul. 401, Mar., 1915.....	142	Teaching Agriculture in Second-	
Bul. 401 (abridged); Mar.,		ary Schools, E. Merritt.....	195
1915.....	142	Bul. 214, Spring Wheat in the	
North Dakota Station:		Great Plains Area, E. C. Chil-	
Bul. 111, Mar., 1915.....	140	cott, J. S. Cole, and W. W. Burr.	137
Twenty-fifth An. Rpt., 1914,		Bul. 216, Cotton Warehouses: Stor-	
pt. 1.....	138, 196	age Facilities now Available in	
Twenty-fifth An. Rpt., 1914,		the South, R. L. Nixon.....	191
pt. 2.....	164, 196	Bul. 225, A System of Accounting	
Oregon Station:		for Cooperative Fruit Associa-	
Bul. 126, Feb., 1915.....	142	tions, G. A. Nahstoll and W. H.	
Porto Rico Board of Agriculture		Kerr.....	191
Station:		Bul. 236, A System of Accounts for	
Bul. 8, 1915.....	122, 136	Farmers' Cooperative Elevators,	
Bul. 9, 1915.....	121	J. R. Humphrey and W. H.	
South Carolina Station:		Kerr.....	192
Bul. 180, Dec., 1914.....	158	Bul. 237, Strawberry Supply and	
West Virginia Station:		Distribution in 1914, W. A.	
Bul. 147, Nov., 1914.....	140	Sherman, H. F. Walker, and	
Bul. 148, Dec., 1914.....	173	O. W. Schleussner.....	142
Insp. Bul. 3, Feb., 1915.....	126	Farmers' Bul. 660, Weeds: How to	
<i>U. S. Department of Agriculture.</i>		Control Them, H. R. Cox.....	139
Jour. Agr. Research, vol. 4, No. 1,		Farmers' Bul. 662, The Apple-tree	
Apr., 1915.....	107,	Tent Caterpillar, A. L. Quaint-	
125, 147, 148, 149, 150,	178	ance.....	155
Bul. 125, Zygadenus, or Death		Farmers' Bul. 672, The Agricul-	
Camas, C. D. Marsh, A. B. Claw-		tural Outlook.....	192
son, and H. Marsh.....	177	Office of the Secretary:

EXPERIMENT STATION RECORD.

VOL. XXXIII.

AUGUST, 1915.

No. 2.

A year has passed since the cooperative agricultural extension act of May 8, 1914, commonly known as the Smith-Lever Extension Act, went into effect. In that period much has been accomplished in creating or perfecting the administrative machinery for carrying on the extension work in agriculture and home economics in the Department and the several States. The general lines along which these extensive enterprises will be conducted have also been quite well determined.

All the States have assented to the provisions of the Act either through their governors or their legislatures and the action of the governors has been ratified by all the legislatures which have been in regular session during the year. A single agricultural college in each State has been designated as the beneficiary of this Act, thus providing for a unified administration of the Act within the State. In several States where the college designated is not coeducational, a cooperative arrangement for the work in home economics has been made with the State college for women, and similarly in a few States having separate land-grant colleges for negroes a cooperative arrangement has been made for extension work among people of that race.

In all the States the colleges having charge of the work under the Smith-Lever Act have created extension divisions or services and have brought under these divisions all their extension work in agriculture and home economics whether carried on with Smith-Lever or other funds. In some States these divisions are not yet as clear-cut as is desirable, and in some cases old state laws or general administrative regulations of the institutions adopted years ago have thus far continued a confusing union of the extension organization with that of the experiment station. In thirty-two States a separate officer is in charge of the extension work usually under the title of director, in thirteen States the extension director is also director of the experiment station or dean of the college of agriculture, and in three States there is still an acting director. In almost every State the extension work has already become such a large and varied enterprise that a separate officer in active charge of its operations

and devoting his entire time to this work is essential to its highest efficiency.

In twenty States the farmers' institutes are still carried on by the State Department of Agriculture, though in a number of States there is a movement for their transfer to the agricultural college and this has taken place in South Dakota. In practically all the States where the institutes have a separate organization there is some kind of a cooperation with the agricultural college in this work. Where the institutes are under the direction of the college they are undergoing more or less reorganization with a view to making them more definitely demonstrational and educational.

The plans for the unifying of the management of the agricultural extension enterprises within the States were met by the Secretary of Agriculture, in the first place, by the creation of a States Relations Committee, for the general supervision of all the extension enterprises of the department bureaus and of the cooperative arrangements with the State institutions involving the use of Smith-Lever or department funds for demonstrations or other forms of extension work. This committee has now been succeeded by a permanent States Relations Service, created by Congress in accordance with the Secretary's recommendations, which, beginning with July 1, 1915, will have among its functions the duties previously performed by the States Relations Committee.

All the State agricultural colleges receiving the benefits of the Smith-Lever Act have entered into cooperative relations with the Department, and in forty-six States these institutions and the Department are conducting all their extension work in agriculture and home economics under the terms of a general "Memorandum of Understanding," which is used as the basis for a great variety of cooperative project agreements.

There has been remarkable unanimity in the acceptance by the States of one of the fundamental features of the extension enterprises which was developed by the Department with funds wholly under its control prior to the passage of the Smith-Lever Act. The experience of the past 12 years has fully demonstrated the value of the county agricultural agent as a means of bringing to our agricultural people on their farms and in their homes the results of practical experience and scientific research in agriculture and home economics and securing the practical application of these results through demonstrations and otherwise. There is therefore general agreement that nothing is more important in the development of extension features under the new conditions arising from the Smith-Lever Act than the establishment in each county of permanent headquarters for extension

work, in charge of a competent county agent, who shall act as the joint representative of the local community, the State through its agricultural college, and the Nation through its Department of Agriculture. It is believed that in this way the need of the agricultural people in their several communities can be best determined, and whatever help the State and the Nation can give them in their agricultural and home problems can be most speedily and effectively brought to them. A large share of the department extension funds, much money derived from State, county, and local sources, and a considerable portion of the Smith-Lever fund have therefore been devoted to the maintenance and extension of the county agent system. There are now over 1,000 counties in the forty-eight States which have county agents.

On the whole these agents have been very successful in winning the support and confidence of the farming people and the tangible results of their work are very encouraging. The personality of the agent is, of course, a very large factor in determining the measure of his success. His understanding of the real problems of the region in which he is working, his sympathy with rural people, and his ability to meet them on their own ground and actually to convey to them important practical instruction and information in a convincing way are among the essentials. When to these qualifications are added studious inclinations and habits, the possession of accurate and up-to-date knowledge of the practice and science of agriculture and business ability of high order we have a very able and useful man whose services will mean much for the agricultural and social advancement of his county.

Considering the limited number of agricultural college graduates and the numerous avenues for congenial work which are opening up to them it is not surprising that up to the present time it has not been practicable to obtain a sufficient number of such graduates with the practical experience and other qualifications required for the position of county agent. There will be a steady demand for men of thorough training, combined with satisfactory practical experience, to fill these positions. The colleges have therefore a special duty to train the future extension workers and it is encouraging to notice that they are beginning to feel their responsibility in this direction.

Inasmuch as it is impracticable for the county agent to deal altogether with individual farmers, the problem of the organization of groups of farm people through whom they may work is assuming great importance. Two general types of such organizations are now being utilized. County organizations, often called farm bureaus, are being formed which are expected to take the initiative in securing county or local financial support for the county agent,

take part in the selection and appointment of the agent, and stand behind him in his efforts to advance the agricultural interests of the county. Many of these organizations include business and professional men, as well as farmers, and their complex organization has given rise to special problems. It is, however, now very apparent that while the cordial sympathy and support of all classes of our people in the movement for the improvement of agricultural conditions is very much to be desired, the farming people themselves should control and in the end determine the character and work of the organizations on which the extension system must depend for its local support.

Another type of local organization being tested in various places is the small community club. Where a considerable number of these clubs exist in a county they are often confederated to form some kind of a county organization. The exact relations of organizations of either type to the extension system, the breadth and variety of their functions relating to extension work or other enterprises, and the most effective forms for their organization are as yet largely undetermined and they must still be considered as in the experimental stage.

Another important line of extension work which has been developed in a large way by the Department and the agricultural colleges prior to the passage of the Smith-Lever Act and which has been carried over into their new extension organizations is the boys' and girls' club work. In the Southern States this enterprise is organically associated with the county agent work, but in the other States has a more separate organization. Through the club work the extension agencies are brought into close touch with the State and local officers and teachers, who largely cooperate in the formation and management of the clubs. This has raised many interesting questions regarding the relations which the club work might or should sustain with the regular school instruction in agriculture and home economics. For example, is it practicable and desirable to consider the club work as in the nature of a home project for the pupils and to give school credit for this work? Undoubtedly such questions will require much consideration by the extension officers in the future.

For many years the agricultural colleges have done a large amount of extension work through the members of their faculties and experiment station staffs. At first this was purely incidental to their regular duties, but as the demand for extension work has grown a somewhat definite and, in many cases, a large share of the time of specialists in various branches of agriculture and home economics has been devoted to this work. More recently in some institutions

certain officers have been set apart wholly for this service. With the coming of larger funds for extension work under the Smith-Lever Act, much attention is being given to the enlarging and strengthening of the force of extension specialists in practically all the States.

These officers are expected to supplement the work of the county agents by giving them advice and assistance in connection with special problems which arise in the counties, to carry on short practical courses of instruction, often called movable schools, in various parts of the State, to conduct demonstrations along special lines, to prepare extension publications, to address meetings of farmers, to answer the inquiries of county agents or farmers on a great variety of subjects, etc. In general, they are to gather up the available knowledge in their several specialties, and especially the knowledge obtained by the state experiment stations which bears directly on the farmers' problems within the State, to put this knowledge in effective form for delivery to the farming people, and to carry it to them directly or through the county agents by word of mouth, demonstrations, or publications.

The organization of such a force on a large scale is giving the administrative officers of the colleges much trouble and perplexity. The determination of the status of the extension specialists as members of the college faculties and their relations to the teaching force and the station staffs is by no means an easy or simple matter. The question as to how far the extension specialists should devote all their time to extension work or should combine such work with teaching or research is a very complicated one. Obviously there is great danger that persons employed on the extension staff will waste much time and energy in traveling about on indefinite errands, will do too much offhand talking or writing, will be content to be superficial students of their subjects, will not give sufficient attention to the planning and conducting of worth-while demonstrations, will make their teaching too theoretical or sensational, etc.

The standardization of the work of extension specialists has hardly begun. The colleges are practically compelled to increase their numbers rapidly by the appointment of the best available personnel. They must not, however, neglect to establish some reasonable system for scrutinizing the work of these officers with a view to determining its real value as measured by its practical results. It is believed that such specialists should be called upon from time to time to outline their work quite definitely in project statements to be reviewed and approved by the extension director. They should be encouraged to restrict their principal endeavors in any one year to a few well-chosen and strictly limited subjects and should be made to feel that their success will be measured largely by their ability to

secure definite results along these lines. Many of the projects for specialists thus far submitted to the Department under the Smith-Lever Act are far too general and do not reveal any thorough study of what is actually needed or feasible. This is undoubtedly due in part to the rush of work imposed on the extension officers during the past year, and it will be expected that there will be definite improvement along this line in the near future.

The difficulties of the colleges in the proper development of their extension staffs and enterprises are greatly enhanced by the extravagant expectations regarding the immediate effect of this work on our agricultural advancement entertained by the public, partly as a result of enthusiastic propaganda conducted by various agencies. Agricultural advancement over large areas and among farming people of very diverse elements is necessarily a slow process. Superficial results, often very beneficial as far as they go, can be obtained, it may be, in a comparatively short time. Propagandas wisely planned may be useful but they will fail of permanent success unless they are followed up by patient and continuous education.

The Smith-Lever Act has provided the means for a permanent system of popular practical education in agriculture and home economics, so organized as to preserve the autonomy of our state agricultural institutions, to encourage and develop local initiative and self help, and at the same time to bring to the support of the state institutions and local organizations the National Department of Agriculture with its broad outlook on our agricultural problems and its force of scientists and experts who have specialized in various lines or have had wide opportunities for study and observation in certain directions. The most encouraging thing about the extension development in the United States during the past year has been the formation on a grand scale of a cooperative system involving national, state, and local organizations and the general good will and cordiality which has marked the relations of these agencies in the inauguration of this system. A few of the major features of this vast enterprise and some of the outstanding administrative problems with which it will have to deal have been briefly touched upon in this article. It is obviously impracticable in so short a space to give an adequate idea of the immense range and great intricacy of a work which will ultimately touch every phase of the industrial, home, and community life of our agricultural people.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Organic constituents of Pacific coast kelps, D. R. HOAGLAND (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 1, pp. 39-58*).—The object of this work was to study the organic constituents of California kelps. The following species were examined: *Macrocystis pyrifera*, *Nereocystis luetkeana*, *Pelagophycus porra*, *Egrecia laevigata*, *E. menziesii*, *Laminaria andersonii*, and *Iridaea* sp.

Qualitative examination showed the presence in the kelps of complex compounds in a highly colloidal state, but starch and reducing sugars were absent. In all cases a furfurol test was obtained and some samples gave the galactan test, i. e., for mucic acid, after oxidation with nitric acid.

The average results of quantitative analyses of kelps are given in the following table:

Average composition of the organic matter of Pacific coast kelp, calculated on whole plant.

Kind of kelp used.	Number of samples analyzed.	Percentage composition calculated to a water-free basis.								
		Moisture.	Total salts.	Total organic matter.	Protein (6.25).	Ether extract.	Crude fiber.	Pentosans.	Water soluble alcohol precipitate.	Sodium carbonate fraction (algin).
<i>Macrocystis pyrifera</i> , harvestable portion, San Diego.....	8	86.3	38.2	61.7	7.4	0.34	7.2	7.7	6.6	18.7
<i>M. pyrifera</i> , harvestable portion, Pacific Grove.....	4	87.7	42.9	56.9	13.4	.40	7.6	6.3	8.7	14.4

<i>Iridaea</i> sp., entire plant.....	1	80.1	31.4	68.8	17.0	.44	10.5	.9	1.3	1.0

Much of the nitrogen present in kelp is in the nonprotein state. Extractions indicated that one-fifth to one-third was soluble in cold water, which about corresponds to the figures obtained for nonprotein nitrogen. The water extracts from a number of samples of ground kelp were analyzed for acid amid

and ammonia nitrogen. "Protein nitrogen was precipitated by means of phosphotungstic acid, the filtrate boiled in an 8 per cent solution of hydrochloric acid and distilled in the presence of an excess of magnesium oxid. In all cases the amount of nitrogen so estimated was insignificant."

The most important carbohydrate constituent of kelp is algin, obtained by digesting cold for 24 hours with a 2 per cent sodium carbonate solution and precipitating from the filtered extract with dilute hydrochloric acid. The percentage of algin obtained varied from 13 to 24 per cent when calculated on a dry basis. An exception was *Iridwa* spp., which only showed 1 per cent of the complex. The composition of a purified, bleached with sulphurous acid, and dried sample of algin was as follows: Nitrogen, 0.3 per cent; ash, 2.2 per cent; furfural calculated to pentosans, 38.6 per cent; and material insoluble after treatment with concentrated nitric acid (cellulose derivative) 24.5 per cent. Algin is regarded as a very complex resistant compound (or mixture of compounds) of the pentosan type, with cellulose possibly making up a part of the complex. It has weakly acid properties, forming soluble compounds with the alkali metals. The properties of soluble and insoluble alginates are described.

The carbohydrates in kelp precipitable by alcohol were smaller in quantity than algin, and in *M. pyrifera* the stems showed uniformly higher percentages than the leaves. The dried substance contained 1.2 per cent of nitrogen and yielded furfural, corresponding to 13.2 per cent of pentosan. No color test was given with iodine and no reduction with Fehling's solution. The moist precipitate when boiled several hours with a 2 per cent solution of sulphuric acid reduces alkaline copper solution considerably. Upon drying, the precipitate became very resistant to solution and to hydrolysis. A composite sample of fiber, obtained as in the crude fiber method, was treated by the chlorination method of Cross and Bevan (E. S. R., 28, p. 805) and showed that approximately one-half of the crude fiber, or calculated on the whole dry plant, 3 to 4 per cent was composed of pure cellulose.

Dried kelp when treated with 2 per cent sulphuric acid was very resistant to hydrolysis and yielded copper-reducing substances only with difficulty. Kelp was found to contain a considerable portion of water-insoluble sulphur, which is regarded as organic sulphur. The leaves contained uniformly more sulphur than the stems. Volatile sulphur compounds could not be noted. The iodine of dried kelp was found almost entirely soluble in cold water or in 90 per cent alcohol.

Although Pacific coast kelps contain an appreciable amount of nitrogen, it is doubtful whether they can be considered an important feeding stuff. Although the percentage of acid amid nitrogen is apparently very small, it is necessary to prove that the remainder of the soluble nitrogen is present in the form of suitably proportioned amino acids before a high nutritive value can be assigned to the material. "Furthermore, the nitrogenous compounds would undoubtedly be rendered less available because of the admixture of large percentages of highly resistant polysaccharids." Another factor which must be taken into consideration is that cows will not eat the leached or unleached fresh kelp unless it is well mixed with other feed. "In order to ascertain whether kelp might be preserved in the fresh state as a sort of silage, a sample of *N. luetkeana* was packed in an air-tight container and stored for three months. At the end of this period there was no indication of putrefaction. The acidity had increased slightly, the final percentage being 0.18 as lactic acid. The sample had become soft and 'crumbly,' but there was no formation of reducing substances or marked increase in soluble material."

The so-called algin might be employed as a size for paper and fabrics, but whether it is economically feasible is questionable. Its physical properties are not well adapted for clarifying wines. As leached kelp only has a small amount of cellulose its use for paper making is questionable, especially in view of the fact that redwood wastes and other wastes of much greater possibilities are still to be utilized.

Destructive distillation of kelp side by side with Douglas fir shavings and oak sawdust showed "that the distillates from the kelp, judged by their content of acetic acid and alcohol, had a value of only one-fifth to one-tenth that of the oak and fir distillates, a value so slight as to preclude any profitable recovery of the products. The yields for oak and fir approximate those obtained in larger experiments on similar materials, and it is very probable, therefore, that the general comparisons with kelp would hold even in distillations on a commercial scale. The distillates obtained from the kelp were watery in appearance and had a very slightly acid reaction to litmus, although they contained considerable amounts of basic substances. By the Kjeldahl method 3.2 gm. of nitrogen was found in the total distillate from 1 kg. of dried kelp. The tar oils obtained with the distillate floated on the surface, having a specific gravity of 0.984. Their percentage varies from 4 to 7 on the basis of the dry kelp. The gases evolved from the kelp differ from those of the oak and fir in not being combustible during any of the earlier stages of distillation. The charcoal residue in the retort was soft and of dull-gray color. Leaching experiments indicated that most of the potash may be recovered from the char as a high-grade product."

A bibliography of cited literature is appended.

The theory of alkalimetric and acidimetric titrations, N. BJERRUM (*Samml. Chem. u. Chem. Tech. Vorträge, 21 (1914), No. 1-3, pp. IV+128, figs. 11*).—This book contains material given in a course of lectures at the University of Copenhagen in the spring of 1913. The book is divided into three sections. The first part deals with the present views regarding acid and basic reaction, the strength of acids and bases, and the hydrolysis of salts. The second part considers the law of indicators with special regard to volumetric analysis. The third part deals with the principles of titration.

A comparison of the Gunning-copper method with the Kjeldahl-Gunning-Arnold method for the determination of nitrogen, O. F. JENSEN (*Jour. Indus. and Engin. Chem., 7 (1915), No. 1, pp. 38, 39*).—A quantitative yield of ammonia was obtained more quickly in dried blood by the Kjeldahl-Gunning-Arnold method than with the Gunning-copper method. In the case of other substances studied, which included bone meal, casein, egg albumen (dried), fish scrap, animal tankage, beef scrap, castor-bean pomace, cotton-seed meal, etc., a digestion of one and a half hours was equally efficacious for either of the methods. "The Gunning-copper method possesses advantages in manipulation which makes it preferable to the Kjeldahl-Gunning-Arnold method, especially where a large number of determinations are to be made."

Cleaning soils for microscopic examination, W. H. FRY and J. A. CULLEN (*Jour. Indus. and Engin. Chem., 7 (1915), No. 1, pp. 40, 41*).—For cleaning soils for microscopical mineral work a 10 per cent solution of oxalic acid is recommended. "In about 30 minutes it removes the iron stains satisfactorily. Tests upon various soil minerals showed that, with the exception of apatite, it did not affect them appreciably; and in the case of apatite, although there is undoubtedly some effect, it leaves that mineral in a determinable state. Of

course, in any case calcite would be removed—a fact which renders very difficult the determination of small quantities of this mineral in discolored soils.”

The strength of nitric acid, period of extraction, and ignition as affecting the gravimetric determination of phosphoric acid in soils, O. L. BRAUER (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 12, pp. 1004, 1005).—“Acid weaker than 1 N to 2 N HNO_3 will not extract all the soluble phosphoric acid from a soil. It is needless to extract with the acid for a longer period than two hours on the steam bath. Ignition decreases the HNO_3 -soluble phosphoric acid in the soils.”

The estimation of citric acid-soluble phosphoric acid in Thomas slag powder, NEUBAUER (*Landw. Vers. Stat.*, 85 (1914), No. 3-5, pp. 238-247).—A report by the referee of cooperative work done with the methods for determining citric acid-soluble phosphoric acid given to the Association of Agricultural Experiment Stations of Germany. The methods best suited for the purpose, according to the referee, are the iron citrate method (E. S. R., 29, pp. 409, 410) and the Lorenz method (E. S. R., 13, p. 14; 31, p. 112). Preference is given to the latter method. Discussions of the report by members of the Association are included.

Estimation of water-soluble phosphoric acid in superphosphate mixtures, NEUBAUER (*Landw. Vers. Stat.*, 85 (1914), No. 3-5, pp. 248, 249).—The author believes that better results are obtainable if the flask containing the sample is filled up to the mark before rotation. This confirms the opinion of Pilz (E. S. R., 30, p. 809).

About the titrametric estimation of cyanamid, G. GRUBE and J. KRÜGER (*Ztschr. Angew. Chem.*, 27 (1914), No. 46, Aufsatzteil, pp. 326, 327; *abs. in Chem. Ztg.*, 38 (1914), No. 114-115, *Reprt.*, p. 488).—The authors conclude that the Kappen method (E. S. R., 21, p. 419) and the Caro method (E. S. R., 25, p. 24) will yield identical results, provided the precipitation is done with silver nitrate in a slightly acid (acetic) solution of the cyanamid and the solution is subsequently made slightly alkaline with ammonia. A large excess of ammoniacal salt or free ammonia must not be present.

Examination, sampling, and guaranty of fertilizing lime, NEUBAUER (*Landw. Vers. Stat.*, 85 (1914), No. 3-5, pp. 228-238).—In cooperative work under the auspices of the German Association of Agricultural Experiment Stations six limes were studied by the Tacke sulphuric acid titration (official) method, the Förster hydrochloric acid titration method, and the Fresenius method.^a

The figures obtained by the Fresenius method were much more uniform than those given by the Tacke method and the operation is more simple than the latter method. Both methods, however, can be used only for comparatively pure limes. The method of sampling in use by the association is deemed inadequate.

Blood charcoal as a purifying agent for arsenic solutions previous to titration, R. M. CHAPIN (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 12, pp. 1002, 1003).—In assaying arsenical dipping fluids, of which an important ingredient is an alkaline arsenite, it often becomes necessary to remove organic material which interferes with the titration by iodine. Organic matter, when present, may absorb iodine and thus render the end points inaccurate and fugitive, and it furthermore imparts color to the solution. Purified kaolin or infusorial earth only obviates the disturbing factor moderately, but in blood charcoal a

^a Quantitative Chemical Analysis, by K. R. Fresenius, trans. by A. I. Cohn, 1904, vol. 2, pp. 334, 335.

substance was found which, when used in small amounts and with brief digestion produced filtrates wherein the end point came out sharply and permanently. Blood charcoal, though slightly absorbing arsenic acid from acid solution, will again release it quantitatively, but more or less oxidized to arsenic acid. When the charcoal is washed this finding may be of considerable value in the determination of both arsenious and arsenic acid in a variety of substances. A test was made of its decolorizing power on a sample of London purple with good results.

See also a previous note (E. S. R., 31, p. 115).

A substitute for potassium permanganate to liberate formaldehyde gas from a water solution, S. G. DIXON (*Jour. Amer. Med. Assoc.*, 64 (1915), No. 5, p. 459).—The formaldehyde solution shipped in combination with sulphuric acid when exposed to extremely low temperatures in winter was not found sufficiently stable for northern climates. By adding $1\frac{1}{2}$ fluid oz. of glycerin to the formula a solution was obtained which is moderately stable at low temperature and will withstand polymerization. The following formula is now used: "Sodium dichromate, 10 oz. avoirdupois; saturated solution of formaldehyde gas, 1 pint; sulphuric acid, commercial, $1\frac{1}{2}$ fluid oz.; glycerin, $1\frac{1}{2}$ fluid oz."

It was also found that when the acidulated solution became cloudy on account of low temperatures it could be made clear and potent by gently warming it for a long period of time.

See also a previous note (E. S. R., 33, p. 12).

An improved method for the estimation of inorganic phosphoric acid in certain tissues and food products, R. M. CHAPIN and W. C. POWICK (*Jour. Biol. Chem.*, 20 (1915), No. 2, pp. 97-114).—The method, which was designed for and effectively used in the determination of inorganic phosphorus in eggs and in meats, is said to possess a sufficient number of advantages to make it superior to the methods of Emmett and Grindley (E. S. R., 17, p. 887), Siegfried and Singewald (E. S. R., 17, p. 635), and Forbes et al. (E. S. R., 23, p. 303). "The Emmett and Grindley method falls short by the use of a neutral solvent and of heat; the Siegfried and Singewald method, by failure to remove the protective colloids, by exposure of the organic phosphorus to the action of the phosphate precipitant, and by the long duration of the initial filtration; and the Forbes method, by the use of heat and the necessity for a double filtration. Finally, Collison's modification of the Forbes method of extraction is open to the criticism that the proteid superficially coagulated by the strong alcohol interferes with the further penetration of the tissue by the solvent."

In the method proposed picric acid solution containing a small amount of hydrochloric acid is used for extracting the phosphorus. "The extraction is complete; bacterial action is prevented, and the proteids are effectually coagulated by the reagent, while the danger of chemical or enzymatic changes is minimized by the low temperature and the rapidity of the extraction. The extract is easily filtered and is practically free from organically combined phosphorus, while by the use of an aliquot of the filtrate for further work, a tedious washing of the precipitate is avoided."

In the method an initial precipitation is made with magnesia mixture and the final precipitation by means of an ammonium molybdate. The phosphoric acid is finally estimated gravimetrically by weighing the ammonium phosphomolybdate by the Lorenz method (E. S. R., 13, p. 14) as modified by Neubauer and Lücker (E. S. R., 27, p. 503). Several modifications of the method are also presented.

"By means of this method a progressive increase in the ratio of the inorganic to the total phosphorus in eggs has been found, which increase corresponds to the increased deterioration of the eggs as judged by physical means." The data on eggs show the total and inorganic phosphorus content.

Methods adapted for the determination of decomposition in eggs and in other protein food products, H. W. HOUGHTON and F. C. WEBER (*Abstr. in Biochem. Bul.*, 3 (1914), No. 11-12, p. 447).—"The methods that are most applicable for the determination of decomposition are the Folin titration and Nesslerization methods for free ammonia, Klein's modification of Van Slyke's method for amino nitrogen, and the Folin-Wentworth method for acidity of fat.

"Calculating the results on liquid eggs to a moisture-fat free basis, the following amounts of ammonia nitrogen in milligrams per 100 gm. of material were obtained: By the Folin titration method—seconds, 11.4; spots, 14.1; light rots, 17.3; rots, 26.2; black rots, 169.6. By the Folin Nesslerization method—seconds, 12.4; spots, 20; light rots, 21.5; rots, 29.9; black rots, 148.6. The amino nitrogen determination is of service in detecting liquid and dry blood rings, spots, and light rots. Increase in the acidity of the fat indicates spots and worse grades of eggs.

"The ammonia methods applied to herring give results indicating decomposition of the fish after standing 24 hours at about 70° F. Applied to clams, an appreciable increase in the ammonia is shown after keeping two days at a temperature of 60 to 65°."

The relation between the specific gravity and the percentage of fat and total solids in cows' milk, W. FLEISCHMANN (*Jour. Landw.*, 62 (1914), No. 2, pp. 159-172).—A review and discussion of practically all of the more important methods for estimating the total solids of milk, etc. A formula is given which yields approximate results under practical conditions.

Morres' alizarol test for testing the keeping quality of milk, A. DEVARDA and A. WEICH (*Arch. Chem. u. Mikros.*, 6 (1913), No. 4, pp. 207-212; *abstr. in Chem. Ztg.*, 37 (1913), No. 128, *Reper.*, p. 586).—The combined alizarol test (E. S. R., 22, p. 515) is a color test combined with the alcohol test which will empirically determine the degree of acidity of milk with an accuracy of 1 per cent. The chief advantage of this test lies in the fact that the alcohol and acidity test can be conducted at one time and can be used by the milk inspector with satisfactory results. Alkaline decomposition products when present vitiate the results.

What value has the alizarol test for the examination of milk as a control of the milk supply? A. DEVARDA (*Österr. Molk. Ztg.*, 21 (1914), No. 2, pp. 17-19).—A detailed criticism of the Morres alizarol test.

With this test it is not possible to determine whether a pure culture has caused coagulation or whether it has been due to a number of organisms. The alcohol test is satisfactory for judging the quality of milk in market control. It is possible to determine approximately the degree of pure lactic acidity of the milk with the alizarol method, but the diagnostic value is thereby limited to the empirical testing of milk, especially as to its value for cheese making. This use was suggested by Eugling in 1882.

The alcohol and alizarol tests, W. MORRES (*Milchw. Zentbl.* 43 (1914), No. 8, pp. 208-211).—The alizarol test is said to be more valuable for testing milk than the alcohol test alone. Eugling's test with alizarin is only a qualitative procedure, while the alizarol test is qualitative and quantitative. It will indicate both the nature and the degree of decomposition, and in this it displaces titration of acidity with alkali as well as the alcohol test. Judging a milk on

the basis of the consistency of the coagulum obtained with the alcohol test alone is deemed uncertain. A method for proving the value of the alizarol test is included in the article.

Titration of milk with alcohol of various concentrations, F. LÖHNIS (*Molk. Ztg. [Hildesheim]*, 28 (1914), No. 9, pp. 153-155).—The alcohol test has been modified as follows:

Two cc. of the milk under examination is placed in a beaker and titrated with 80 per cent alcohol until the appearance of coagulation, the number of cubic centimeters of alcohol required indicating the alcohol number of the milk. The coagulating point of milks which require more than 6 cc. of alcohol is hard to determine. The test is said to be an index to the number of bacteria present in the milk, a milk with a low germ content requiring more than 4 cc. of alcohol, while that of a medium micro-organism content requires from 2 to 4 cc., and high germ contents less than 2 cc.

The alcohol test in relation to milk, S. H. AYERS and W. T. JOHNSON, JR. (*U. S. Dept. Agr. Bul. 202 (1915), pp. 35, figs. 4*).—The purpose of this work was to determine the practical value of the alcohol test for the quality of milk, and incidentally to determine some of the causes for the coagulation of milk by alcohol.

Fresh milk from a single healthy cow in the middle of the period of lactation was found to give occasionally a positive alcohol test with an equal volume of 68 or 70 per cent alcohol. Colostrum gives a positive reaction, and the same is true, usually, of "old" milk (milk from a cow in the last of its lactation period). Normal milk when mixed with colostrum milk did not show positive with the 68 per cent alcohol test until the amount of colostrum milk reached 80 to 90 per cent. "When 75 per cent alcohol was used the test was positive with as low as 25 per cent of colostrum milk, but when colostrum milk from another cow was used a mixture of 80 per cent was required to give a positive reaction with 75 per cent alcohol. It seems evident from these results that the mixing of colostrum and normal milk would not cause a positive alcohol test unless a very large percentage of the milk were colostrum milk."

As a result of reviewing the literature on the behavior of the alcohol test with market milk, it was evident that the acidity plays a part in the alcohol test. In the present investigation it was found that if the acidity was raised by the addition of 1 cc. of decinormal lactic-acid solution, a medium-sized flake coagulum with 75 and 68 per cent alcohol could be obtained. "Since an increase in acidity will cause a positive alcohol test, it is evident that the growth of acid-forming bacteria in milk will cause a positive test.

"In order to determine the relation between the number of acid-forming bacteria, the acidity, and the alcohol test, two experiments were performed, using a pure culture of a lactic-acid-producing organism." In one of the samples of milk the alcohol test was negative 7 hours after incubation, but in the second sample, where a larger portion of bacterial culture was used for the inoculation (at the beginning of the incubation 480,000 bacteria were present), the alcohol test with 75 per cent alcohol was positive on the fifth day, when the number of bacteria reached over 16,000,000. On the sixth day 68 per cent alcohol gave a positive test and the number of bacteria was 31,400,000.

Since the acidity of milk is due partly to phosphates, the effect of sodium and potassium acid phosphates on the outcome of the alcohol test was studied. "The results show that it is possible by increasing the acidity of milk with acid phosphates to cause a coagulation with the alcohol test, but the acidity has to be increased to a high degree, and there would never be enough acid phosphate in a mixed market milk for it to be entirely responsible for a positive alcohol test. . . . When from 7 to 8 cc. of decinormal lactic acid was

added to the milk with dibasic phosphate, the alcohol test became positive; that is, when the dibasic phosphate had been converted into monobasic phosphate, then further increases in acidity caused a positive alcohol test. As a very general explanation of this result, it may be said that when acid is added to milk it converts the dibasic phosphate into the monobasic phosphate. It follows that the acid, and also the monobasic phosphate, probably affect the casein and thereby change it into a condition in which it is possible to precipitate the casein by alcohol and cause a positive test. This action on the dibasic phosphate probably explains in part the positive alcohol tests with different low acidities."

The addition of 1 per cent of sour milk to fresh milk caused a positive alcohol test with 75 per cent alcohol and the addition of 2.5 per cent of sour milk caused a reaction with 68 per cent alcohol. As much as 10 per cent of sour milk was necessary to cause coagulation with 44 per cent alcohol. Milk in which the acidity was increased to 4.3 per cent by the addition of lactic acid and then reduced to 1.9 per cent by neutralization gave a positive alcohol test with 68 per cent alcohol. "The positive alcohol tests with 68 per cent alcohol could be made negative at acidities below 4.3 by reducing to about the original acidity of the normal milk."

Some milks when heated to 90° C. will not give the alcohol test with 75 or 68 per cent alcohol.

To determine the effects of rennet on the outcome of the alcohol test (75, 68, and 44 per cent) rennet in percentages ranging from 0.00005 to 0.0015 was tried and the tests with alcohol were made at intervals of one hour. "The results show that the action of rennet in milk may produce changes which cause a positive alcohol test and that two main factors are of importance, viz, the amount of rennet and the length of time the rennet has to act. Undoubtedly a third factor must be taken into consideration; that is, the temperature at which the milk is held. In the experiments the milk was held at room temperature." The activity of rennet-forming bacteria may cause a positive alcohol reaction but the number of bacteria propagated must be large. A test indicated that it is also possible to differentiate between an acid and rennet fermentation in milk on the basis of the alcohol test. When sufficient rennet was added to milk to cause a positive alcohol reaction and then heated to 90° C. the milk no longer gave a positive alcohol test with 75 per cent alcohol, although rennet and acid probably play the principal rôle in obtaining a positive alcohol test.

The presence of carbon dioxid may also be considered a factor. Carbon dioxid passed into milk will cause an alcohol test. Alkali-forming bacteria will not cause a positive alcohol test. With samples of market milk no relation was found between the bacterial count and the alcohol test. In this work particular attention is drawn "to the bacterial counts of 142 samples of raw milk which ranged from 2,000 to 19,600,000 bacteria per cubic centimeter. Of these 142 samples none gave a positive alcohol test, yet 86, or 60.6 per cent, contained less than and 39.4 per cent more than 500,000 bacteria per cubic centimeter. The bacterial counts of samples of pasteurized milk which gave a negative alcohol test ranged from 1,200 to 3,600,000 per cubic centimeter. . . . When the 68 per cent alcohol test is positive with a sample of market milk, it is evident that there is some change in the milk from normal. In some cases it may be due to an increased acidity and in consequence a change in the casein of the milk, due to bacterial action. In other cases it may be due to a pure rennet fermentation or there may be a combination of an acid-and-rennet fermentation. In such cases the bacterial count would undoubtedly be high. However, there still remains to be explained the reason for a positive alcohol test in samples of market milk with a low bacterial count and low acidity."

The alcohol titration method of Löhnis (see p. 113) was tested on 116 samples of market milk. No definite relation between the bacterial count and the alcohol titration test was found. There was also no definite relation found between the alcohol test and the acidity, until the acidity was more than about 2.2 per cent. "If we were dealing with pure cultures of organisms which influence the alcohol test the titration with alcohol might be of value in giving an idea of the bacterial numbers from the results of experiments in which we used pure cultures of lactic acid and rennet-forming bacteria. In milk, however, we have a varied bacterial flora to contend with and we can not see from our results that the alcohol titration method is of much greater value than the simple alcohol test."

With the alizarol test of Morres (see p. 112) all of the color changes described by Morres could not be obtained. From the results obtained it is evident that the alizarol test will show slight changes when the acidity is low, but that when the acidity is high it is not very sensitive. "In regard to the value of the alizarol test, it is believed that wherever the alcohol test can be considered of value, the addition of an indicator, such as alizarin, may increase the value of the alcohol test by possibly giving additional information as to acidity. On account of the complexity of the bacterial fermentations in market milk we do not believe that the alizarol test gives any very valuable information as to the conditions existing in the milk."

A bibliography of cited literature is appended.

Some milk investigations with special reference to the value of the rosolic acid-alcohol test, L. BAHR (*Ztschr. Fleisch u. Milchhyg.*, 24 (1914), Nos. 10, pp. 228-233; 11, pp. 251-256; 16, pp. 370-376, figs. 4; 17, pp. 398-406; 20, pp. 472-477; abs. in *Berlin, Tierärzt. Wchenschr.*, 30 (1914), No. 44, p. 734).—In examining the milk from 105 cows located in five establishments with the rosolic acid-alcohol test (E. S. R., 26, p. 87), about 16 per cent gave positive reactions. This was especially true in those cases where the titer against normal alkali was somewhat below normal. The rosolic acid reaction probably depends upon the presence of secondary or tertiary phosphates.

Generally speaking, the results with the test compared well with the leucocyte and catalase tests, which sometimes give a higher number of positive findings. In the majority of the milks in which the rosolic acid-alcohol test was positive the milk contained many bacteria, leucocytes, and fibrin. There were also reactions obtained with milk from a cow in an advanced stage of lactation, but this milk did not show a large amount of leucocytes or bacteria. A few tests made with methylene blue indicated that it had no relation to the number of bacteria present in the milk.

The rosolic acid test may be employed for detecting cows affected with mastitis, especially those in which it is not clinically manifest, and is considered a good barn test. The catalase test indicates a larger number of animals giving pathological milk, and it is believed that this also may be so arranged that it can be used as a practical test in the dairy barn. The bacteriological examination of the milks revealed that some of them contained ordinary streptococci (mostly diplococci) amongst which there was one type which resembled the one causing mastitis. In a few cases a previously undescribed bacillus (*Bacillus pseudopyogenes lactis*) was noted and in others staphylococci and small nonacid-fast bacilli were found.

The use of Kellner's modification of Petermann's method for the estimation of citrate-soluble phosphoric acid in feed limes, LOGES (*Landw. Vers. Stat.*, 85 (1914), No. 3-5, pp. 218-226).—This is a report made to the German Association of Agricultural Experiment Stations. It is stated that duplicate results can only be obtained when the mixture is shaken the same length of time in each case.

A study in drying urine for chemical analysis, W. W. BRAMAN (*Jour. Biol. Chem.*, 19 (1914), No. 1, pp. 105-113).—In these investigations it was found that some urines from herbivora on drying lose nitrogen from ammonium compounds and free ammonia, in some cases as much as 50 per cent of this nitrogen. The main loss of nitrogen, however, comes from the decomposition of ammonium carbonate rather than from that of urea or hippuric acid. The carbon loss, which consists of carbon dioxide, is in excess of what would be necessary to combine with the ammonia to form normal carbonates, and comes partly from the bicarbonates. The total carbon and total hydrogen can be determined directly by combustion in a quartz combustion tube using the ordinary combustion furnace.

The quantitative estimation of urea, and indirectly of allantoin, in urine by means of urease, R. H. A. PLIMMER and RUTH F. SKELTON (*Biochem. Jour.*, 8 (1914), No. 1, pp. 70-73).—"The estimation of urea in urine is quickly and accurately made by decomposing it with urease (1 gm. powdered soy bean) at 35 to 40° C. for one hour. During this time the ammonia evolved is removed by an air current, as in Folin's method for estimating ammonia. One gm. of anhydrous sodium carbonate is then added and the air current is continued for another hour. Liquid paraffin is very convenient for lessening the frothing. Since urease does not decompose allantoin, and since both allantoin and urea are quantitatively decomposed by the magnesium chlorid method of Folin, the amount of allantoin in those urines which contain both compounds is readily estimated by difference."

A permanent preparation of urease, and its use for rapid and accurate determination of urea, D. D. VAN SLYKE and G. E. CULLEN (*Jour. Amer. Med. Assoc.*, 62 (1914), No. 20, pp. 1558, 1559, fig. 1; *Jour. Biol. Chem.*, 19 (1914), No. 2, pp. 211-228, figs. 3).—Soy-bean meal is extracted with five parts of water and the extract is poured into ten volumes of acetone. The precipitate containing the enzyme is dried and obtained as a powder, which is said to maintain its action indefinitely. The ammonia evolved is collected in fiftieth-normal acid, which may be either hydrochloric or sulphuric.

METEOROLOGY.

Relation of climate to plant growth in Maryland, F. T. McLEAN (*Mo. Weather Rev.*, 43 (1915), No. 2, pp. 65-72, figs. 3).—Selected strains of wheat, corn, soy beans, and Windsor beans were grown in nine different localities on the same type of soil in 6-in. pots sunk in the ground, and an attempt was made to correlate the growth of the plants with the meteorological environment, viz, rainfall, evaporation, temperature, and sunshine. To eliminate the disturbing influence of drought, the soil moisture in the pots was prevented from falling below the optimum by the use of an autoirrigator. Evaporation was measured by means of a Livingston atmometer.

Only the results obtained with soy beans at Oakland and Easton are discussed in this article. These indicate that with a sufficient supply of moisture provided for, the soy bean "exhibited a pronounced and somewhat regular march of its growth rate (as measured in terms of the dry-weight material accumulated in leaves and stems during the first month of its growth from seed) throughout the growing season," the maximum rate of production of dry matter occurring in the warmest part of the season. "The growth rate tended to vary almost directly with the 'temperature index' [mean daily temperature above 40° F.] when the air temperatures were low. With high air temperatures the growth rate was relatively much greater than can be accounted for by the 'temperature indexes' alone. The agreement in this regard between the data

from the two very different stations included in these studies seems to suggest that this feature may be general for a considerable range of conditions, at least for the plant form here considered. With the given soil and soil moisture content the intensities of evaporation experienced by these soy-bean plants were apparently not sufficiently high seriously to overtax the process of water absorption or that of water conduction." It therefore appears that the seasonal changes in temperature were "much more important in the control of growth than were the changes in any other measured condition or conditional complex."

In general the rates of growth at Oakland were found to be from about 10 to about 20 per cent or more lower than the corresponding rates at Easton. "The early occurrence of frost at Oakland brought the season to a close earlier than was the case at Easton, and the last growth rate for the latter station is shown as markedly lower than any encountered at Oakland. The principle here brought out is worthy of considerable emphasis. For a short frostless season, characterized by a great daily range of temperature, the lowest growth rate may be generally expected to be higher in value than the lowest rate for a longer frostless season, with more equable temperatures."

A correlation of weather conditions and production of cotton in Texas, J. B. KINCER (*Mo. Weather Rev.*, 43 (1915), No. 2, pp. 61-65, figs. 9).—In this article an attempt is made to correlate the actual departures from mean temperature and precipitation with the departures from the average yield of cotton during the period from 1894 to 1913, inclusive.

The results show a correlation coefficient of $+0.88$ and a probable error of ± 0.03 . The method, however, was found to be inapplicable where the summer rainfall frequently occurs in excessive amounts. In such cases it is necessary to take account of the rainfall actually absorbed by the soil and that which is removed in the run-off.

Temperature and spring wheat in the Dakotas, T. A. BLAIR (*Mo. Weather Rev.*, 43 (1915), No. 1, pp. 24-26, figs. 2).—Continuing studies reported in a previous article (*E. S. R.*, 30, p. 418), the author is led to modify the conclusions from his earlier study to the extent of stating that the mean temperature of June is as important a factor as the total precipitation of May and June in determining the yield of wheat in the Dakotas.

The distribution of the rainfall in the eastern United States, B. C. WALLIS (*Mo. Weather Rev.*, 43 (1915), No. 1, pp. 14-24, figs. 18).—From studies similar to those already noted (*E. S. R.*, 32, p. 119) the author draws the following general conclusions: "The rainfall intensity as well as the actual amount of precipitation of the eastern United States depends upon three separate factors—(1) the 'swing of the sun,' which has its most marked effect at places farthest from the sea; (2) the local variations in temperature, which give rise to abnormal temperature conditions, which have their most marked effect in causing variations in the months of maximum and minimum intensity of rainfall; (3) the proximity of the ocean, which causes heavy total precipitation near the coast and masks to some degree the effect of insolation."

The eastern United States is divided into three rainfall belts paralleling the Atlantic coast: (1) The interior or continental belt, characterized by summer rains and winter dryness; (2) a belt of rainfall at all seasons, due to the middle position of the area between the continental conditions of belt 1 and the oceanic conditions of belt 3; and (3) a belt of masked summer rains.

Monthly Weather Review (*Mo. Weather Rev.*, 43 (1915), Nos. 1, pp. 56, pls. 24, figs. 39; 2, pp. 57-59+X, pls. 8, figs. 12).—In addition to notes on weather forecasts for January and February, 1915, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on

meteorology and seismology, notes from the Weather Bureau library, the weather of these months, a condensed climatological summary, climatological tables and charts, and seismological reports, these numbers contain the following articles:

No. 1.—The Snowfall of the Eastern United States (illus.), by C. F. Brooks; The Rainfall of the Northeastern United States (illus.), by B. C. Wallis; The Distribution of the Rainfall in the Eastern United States (illus.), by B. C. Wallis (see p. 117); "Monsoon" Rainfall, by B. C. Wallis; On the Use of "Average," "Mean," "General," by H. R. Mill; Temperature and Spring Wheat in the Dakotas (illus.), by T. A. Blair (see p. 117); An Eight-Day Mechanically Recording Rain Gage (illus.), by C. F. Marvin; New Meteorological Stations in Korea, by R. S. Curtice; Meteorological Radiotelegrams to Mariners from Scheveningen; and The Water Resources of Strawberry Creek, Berkeley, Cal. (illus.), by W. G. Reed and H. M. Loy.

No. 2.—The Diurnal Period of the Wind Velocity; The Ascent of Air above Active Volcanoes, by K. Wegener; A Correlation of Weather Conditions and Production of Cotton in Texas (illus.), by J. B. Kincer (see p. 117); Relation of Climate to Plant Growth in Maryland (illus.), by F. T. McLean (see p. 116); New Zealand Rainfall in 1914, by D. C. Bates; and Gigantic Snowflakes. A subject and author index of the Monthly Weather Review, 1914, is also included in this number.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and R. E. McLAIN (*Massachusetts Sta. Met. Buls.* 315, 316 (1915), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during March and April, 1915, are presented. The data are briefly discussed in general notes on the weather of each month.

Instructions for cooperative observers (*U. S. Dept. Agr., Weather Bur., Instrument Div. Circs. B and C. 5. ed. (1915), pp. 37, pl. 1, figs. 10*).—This is a fifth revised edition of this pamphlet, which is designed "to furnish cooperative observers with brief instructions for their guidance in taking and recording meteorological observations, more especially of temperature and rainfall, and for reporting earthquakes." The revision consists mainly in the addition of a section relating to earthquake observations and an index. It is stated that there are now about 4,500 cooperative observers in the United States, and that the records furnished by them "are of great value in affording information upon which many of the important publications of the Weather Bureau are based, and it is the policy of the Bureau to foster and encourage the keeping of such records."

These observers receive no money compensation, but are loaned the necessary instruments and regularly receive such of the publications of the Weather Bureau as can be furnished free of cost. The conditions under which instruments may be secured are explained and instructions are given for the erection and care of instruments and for making and recording observations.

SOILS—FERTILIZERS.

Colloid chemistry in the study of soils, K. K. GEDROÏTS (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 3, pp. 181-216).—This is the second communication on the subject (*E. S. R.*, 28, p. 516), and deals with (1) the speed of the exchange reaction in the soil, and (2) the colloidal nature of soils saturated with different bases and the color method for determining the quantity of colloids in the soil.

Experiments were conducted to determine the speed of the exchange reaction between the calcium (CaO) of chernozem soil and normal solutions of sodium chlorid and ammonium chlorid, and parallel thereto the speed of the exchange reaction between acid sodium phosphate and calcium carbonate. It was found that the reaction between soil calcium and sodium chlorid was instantaneous, and that that between soil calcium and ammonium chlorid, while not instantaneous, was extraordinarily quick. The speed of reaction between sodium phosphate and calcium carbonate was much slower, and it is considered evident, therefore, that the soil calcium is not chemically combined.

To determine the colloidal nature of soils saturated with different bases, 200 gm. portions of a loamy chernozem soil containing 1.395 per cent of calcium oxid were treated 20 successive times with 1 liter of solutions of variable concentration of sodium, potassium, and ammonium chlorids. It was found that such treatment with normal and four times normal salt solutions almost entirely displaced the calcium oxid content soluble in 10 per cent hydrochloric acid.

In a study of the so-called zeolitic compounds in soils samples of chernozem soils were washed repeatedly with water saturated with carbon dioxide until no acid was freed on contact with neutral solutions of sodium chlorid and the water extract was neutral. A comparison of soil so treated with the same soil repeatedly washed with water showed the former to have a much smaller base content but a correspondingly larger colloidal and saturation capacity. It is concluded, therefore, that the zeolitic and humus substances of the soil represent gels of hydrophilous colloids.

Treatment of the chernozem soil with the alkalis sodium, potassium, and ammonium caused the displacement not only of calcium but of iron, magnesia, and potassium, and the soils became saturated, not always exclusively but usually prevailing, with an alkali metal. The colloidal of the soil increased as the saturation with alkali metals increased. This was especially marked when the soil was saturated with sodium. The colloidal was increased less by saturation with ammonia and less still with potassium. It is concluded that when the zeolitic and humus substances are saturated with any of the three alkalis they assume the character of gels of hydrophilous colloids.

Treatment of the original chernozem soil with solutions of iron and aluminum salts caused the displacement of bases, reduced the colloidal, and caused the zeolitic and humus substances to assume the amorphous character of gels of colloids which do not readily take up water.

With reference to the colorimetric method of determining the quantity of colloids in soil, studies were made of the absorption of methyl and crystal violet by eight samples of chernozem soil consisting of the original soil, samples repeatedly treated with 0.2 normal solutions of the chlorids of sodium, potassium, ammonium, calcium, aluminum, and iron, and a sample repeatedly washed out with water saturated with carbon dioxide. A complete adsorption of the coloring matter was observed only by the soil saturated with iron. The adsorption was weak by the soils saturated with aluminum and calcium and the soil washed out with carbon dioxide water. The coloring of the surface film of the samples saturated with potassium, ammonium, and sodium was rather marked, and increased in the order named.

A comparison of the quantities of color adsorbed by the eight soil samples with their so-called colloidalities, that is, the amounts of swelling after saturation with water, showed the color adsorption to proceed not only not parallel with the colloidal but in an opposite direction. It is therefore concluded

that the colorimetric method gives a reverse indication of the amounts of colloids in soils and is an unsuitable method.

The destructive distillation of soil, E. J. HOLMYARD (*Proc. Chem. Soc. London*, 30 (1914), No. 428, p. 109; *abs. in Chem. Abs.*, 9 (1915), No. 4, p. 498).—By the destructive distillation of soils, a distillate of two layers was obtained. The lower aqueous layer was strongly alkaline and smelled of ammonia, and the upper layer consisted of small quantities of a brown oil with an odor like pyridin. Qualitative tests on the lower layer showed the presence of phenol and ammonia. The oil, after the addition of alkali, was distilled in a current of steam, and the pale yellow distillate obtained gave qualitative tests for pyridin, quinolin, pyrrol, thiophene, and possibly furfuraldehyde. Both field soils and garden soils gave similar results. More oil was obtained from garden soils than from field soils.

The results are consistent with the view that the processes of decomposition occurring in the organic matter in soil are similar to those operative in the formation of coal.

Electrolytic determination of the biological solution of soil, E. PANTANELLI (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 42 (1914), No. 15-16, pp. 439-443.)—The author reports studies of the biological solution in 23 samples of desert soils of Tripoli of variable composition, in which he determined the bacterial content of each soil and compared the results of measurements of the electrolytic conductivities of percolates through these soils of water, water and chloroform, 0.5 per cent glucose solution, and 0.5 per cent glucose and chloroform.

By this means it was found that the soil salts were not readily washed out by water, but more so by chloroform and water in 16 cases and less so in 7 cases. With water and chloroform, after seven days at most, considerably more salts were leached out than with pure water alone. Bacterial activity was only slightly stimulated by added moisture, and the chloroform completely inhibited the setting free of soil constituents. In 18 cases the use of the glucose solution was accompanied by an increased washing out of soil salts and a marked solution of soil constituents, which is attributed to an increase in bacterial numbers. With glucose and chloroform more salts were leached out in 7 cases only than with glucose alone, and in 5 cases the chloroform retarded the leaching out. In 11 cases glucose and chloroform caused less leaching out of soil salts than chloroform alone, while in 9 cases the opposite was observed. It is concluded that chloroform increases and glucose sometimes decreases the leaching out of soil salts. Chloroform in the presence of glucose completely inhibited the setting free of soil constituents.

The setting free of soil constituents varied for the most part, but not always, with the bacterial content of the soil. It is thought that this power of biological solution depends less on the total bacterial numbers than on the numbers of individual acid and ammonia formers.

It is concluded that the measuring of the electrolytic conductivity is a suitable method for determining the microbiological solubility of soil constituents, especially when comparative experiments are conducted with and without the use of chloroform and glucose.

Contribution to bacteriological studies of the soil, A. WOJTKIEWICZ (*Centbl. Bakt. [etc.]*, 2. *Abt.*, 42 (1914), No. 10-14, pp. 254-261).—Studies to determine the nature and extent of the influence of methods of management and the different seasons on the microbiological processes in the soil are reported.

The results indicate that the bacterial numbers in soils undergo no extreme variations during the year. The maximum numbers were observed in the spring and the minimum in the winter. The power of the soil to assimilate nitrogen varied greatly with the seasons, the minimum occurring in winter and the

maximum in the fall. In general a certain parallelism appeared to exist between bacterial numbers and the power to assimilate nitrogen.

The optimum temperature for nitrogen fixing bacteria varied with the seasons but somewhat slowly. Temperature variation during the day exerted no influence. Studies of other biological processes produced no conclusive results.

Isolation of *Bacillus radicolica* from soil, C. B. LIPMAN and L. W. FOWLER (*Science, n. ser., 41 (1915), No. 1050, pp. 256-259*).—The methods used with success for the isolation of *B. radicolica* directly from the soil are described, and it is shown that the organism so obtained "at least in some forms and places can be readily made to grow on agar plates in large numbers," thus indicating the desirability of using soil extract-maltose agar for this purpose. The latter was prepared by dissolving 15 gm. of agar and 10 gm. of maltose in a soil extract, of the proper dilution, prepared by shaking 30 gm. of soil for 15 minutes in a sterile bottle with 150 cc of sterile water.

The origin of the "niter spots" in certain western soils, R. STEWART and W. PETERSON (*Jour. Amer. Soc. Agron., 6 (1914), No. 6, pp. 241-248*).—Investigations reported more fully elsewhere (E. S. R., 32, p. 28) are cited to show "that (1) the nitrates of the 'niter spots' are derived by concentration from the original rocks contributing to the soil formation, and that (2) the color of these spots is the direct result of the solvent and decomposing action of the sodium or potassium nitrate upon the organic matter of the soil."

The soils of the western New York fruit and grain region, E. O. FIPPIN (*Cornell Countryman, 12 (1915), No. 5, pp. 368-374, figs. 3*).—This article deals with the characteristics, crop adaptabilities, and fertility requirements of the soils of an area in New York lying adjacent to Lakes Erie and Ontario on the south side.

The natural drainage of the area is poorly developed and the topography is very diverse, varying from flat to undulating. The soils range from heavy stratified clay to loose sand and gravel and are divided into seven series, two of which are of glacial origin, four of lake and swamp derivation, and one of recent alluvial origin. The Ontario series is the most extensively developed in the region. The prevailing soil is a heavy loam to a clay loam. There are extensive areas of silt loam and several small areas of drifting sand, and gravel deposits are widely distributed. "A large part of the land is notably calcareous, especially in the subsoil. . . . In general the stock of organic matter is fairly good but requires attention."

The sandy soil of Sylvan Beach, New York, N. KNIGHT (*Chem. News, 111 (1915), No. 2879, p. 49*).—Analyses of a sandy soil on the eastern shore of Oneida Lake which shows marked oxidizing powers disclosed the presence of much less iron than was expected. The free access of air is thought to be the main reason for the rapid oxidation of organic matter. It is also thought that by the free use of organic manures a fairly rich and productive soil may be formed.

Salts in soils and waters of the south coast of Porto Rico, J. T. CRAWLEY (*Porto Rico Bd. Agr. Expt. Sta. Bul. 9 (1915), pp. 25*).—Continuing work by Zerban (E. S. R., 29, p. 513), this bulletin reports studies of the chemical composition of the soils and irrigation waters of the locality. One of the purposes of the investigation was to show a connection between the existence of so-called "salt spots" and the noticeable deterioration of cane.

The results show that the salt spots and areas affected by salts are widely distributed and of considerable total extent. "In some cases the salt areas are increasing in size and encroaching on the cane areas, while in other cases they are diminishing, and the cane areas extending. The prevalent salts are the bicarbonates, chlorids, and sulphates, and of these the bicarbonates are

more widely distributed than the others. Sulphates are generally found in large quantities in the areas that can not be cultivated, but are often absent, except in small amounts, in the cane areas. Chlorids are found in all samples, but often in such small quantities as to be negligible. . . .

"Where the soil contains from 0.1 per cent to 0.2 per cent of bicarbonic acid unaccompanied by any large quantity of other acids the cane is affected in its growth; beyond this point it rarely thrives. . . . In most cases 0.3 per cent of total acid radicles is very injurious or fatal to the cane, depending somewhat on the relative proportion of the various radicles and upon the frequency of irrigation."

The analyses of irrigation waters show most of these to be excellent for irrigation purposes. The chlorin content is small.

It is concluded that the three chief factors influencing the purity of cane juices from the south coast are root grubs, cane borers, and the salts of the soils.

The application of fertilizers to the soil, and losses by leaching, J. T. CRAWLEY and W. B. CADY (*Porto Rico Bd. Agr. Expt. Sta. Bul. 8 (1915), pp. 17-23*).—Experiments with a lowland clay loam soil, a red clay hill soil, and a sandy clay soil with reference to their absorptive powers for fertilizers are reported.

The results as a whole indicated that phosphoric acid is very quickly and firmly fixed by all the classes of soils, but that there is an appreciable loss from the light sandy soils when the fertilization is followed by repeated irrigations. The nitrogen losses, while the greatest, were of material consequence only in the sandy soils. The clay soils fixed the nitrogen quickly and held it firmly. Potash was lost from all the soils, but in small quantities except in the case of the sandy soils. It is stated that heavy rainfalls or irrigations may wash the potash out before it is fixed, especially from sandy soils, but after becoming fixed it is washed out only in small quantities. There was very little loss of fertilizers from clay soils even after very heavy rains or irrigations. It is thought that there is not the same reason for thoroughly mixing the fertilizers with sandy soils as with clay soils, owing to the tendency for moisture to diffuse the ingredients. It is suggested also that fertilizers should be applied in small and frequent doses to sandy soil rather than in large doses at long intervals.

The effect of fertilizers on the physical properties of Hawaiian soils, W. MCGEORGE (*Hawaii Sta. Bul. 38 (1915), pp. 31, figs. 3*).—This bulletin reports data obtained from an extensive study of the physical properties of Hawaiian soils and the effect of different fertilizers on these properties. Soils of widely differing chemical and physical characteristics and about 40 salts, fertilizer materials, and mixtures were used in the experiments.

It was found that within certain limits the effect of adding a larger application of a salt only magnifies that of a smaller application. Capillarity was diminished in clay soils by the addition of salts but increased in sandy soils. This property was more active in silts than in sandy or clay soils, being slowest in the latter. The percolation of water was most rapid in sandy soils and slowest in types the particles of which are most likely to swell. Fertilizers considerably increased the resistance to percolation. It was found that the theory that soils of greater capillary activity offer the least resistance to percolation of water does not apply to Hawaiian soils.

The results as regards flocculation indicated a relationship between the valency of the salt and its flocculating power. "The most active salt is aluminum sulphate, a trivalent salt. . . . The divalent calcium and magnesium salts of nitric, hydrochloric, and sulphuric acids are next, while the monovalent salts

of sodium, potassium, and ammonium are least active. The acids are stronger than any of their divalent salts but the trivalent salt, aluminum sulphate, is stronger than any of the acids. Nitric acid is the strongest, hydrochloric second, and sulphuric third. Likewise the nitrates and chlorids are stronger than the sulphates."

The cohesion of the soil particles, the apparent specific gravity of the soil in most cases, and the hygroscopicity with but very few exceptions were increased by the addition of salts. The vapor pressure was lowered in most instances but it is stated that this can not be explained from a consideration of the surface tension of the added salts.

The influence of radio-active earth on plant growth and crop production, H. H. RUSBY (*Jour. N. Y. Bot. Gard.*, 16 (1915), No. 181, pp. 1-23, pls. 10, figs. 2, *Sci. Amer. Sup.*, 79 (1915), Nos. 2048, pp. 216-218, figs. 9; 2049, pp. 228-230, figs. 12).—Finely powdered extracted radium ore containing from 2 to 3 mg. of radium per ton was used at rates of 25, 50, 100, and 200 lbs. per acre in mixture with 200 lbs. per acre of "ordinary fertilizer" on a variety of crops grown in window boxes, in a greenhouse, and in field plats at different places.

The general conclusion is that "nearly all, if not all, field crops gave an increased yield under the influence of the proper amount of radio-active fertilizer," the largest increase observed being 135 per cent. The greatest gains reported were obtained with applications smaller than 200 lbs. per acre. Different plants and families of plants showed varying susceptibility to the radio-active fertilizer. "Members of the Cruciferae or mustard family, comprising mustard, rape, cabbage, cauliflower, sprouts, kale, kohlrabi, turnips, and radishes were greatly benefited. So were the Cucurbitaceae, comprising the pumpkin, cucumber, squash, and melons; in fact, more so than any others. The Gramineae, or grass family, comprising hay, corn, sugar cane, sorghum, and lawn grass, was enormously benefited. . . . The effect on a second crop on the same ground was greater than on the first. . . . The effect upon germination, when small amounts are used, was to increase the percentage of seeds germinated and to accelerate the process. The earliest effect of radium is to increase the root growth. Often the stem growth will be retarded for a time, but will later undergo a great acceleration. A given amount of sunlight has produced a greater amount of growth when radium was used, and the same amount of food production has resulted from a smaller amount of green tissue, or tops in case of the greenhouse radishes. An increased tendency to branching has been observed when a large amount of radio-active fertilizer is applied to the soil.

"Perhaps the most important effect of radium was that of improving the edible properties of the product. Potatoes were more mealy. Root crops were remarkably tender, sweeter, and of finer flavor. Beets, carrots, onions, sweet corn, and similar vegetables were markedly sweeter. Tomatoes were also sweeter and chemical analysis showed them to contain less water and more sugar. Radium-grown string beans and peas were peculiarly sweet."

Investigations by others in the same line are reviewed.

Radio-active ores and plant life, H. BASTIN (*Sci. Amer.*, 112 (1915), No. 15, p. 335, fig. 1).—Brief reference is made to experiments with radio-active materials conducted by M. H. F. Sutton, the English seedsman. These experiments were made with ore containing radium as well as with residues from radium manufacture. The crops experimented with included peas, radishes, lettuce, tomatoes, nasturtiums, rape, clover, and various flowering annuals. The amount of radio-active materials used varied from 1 part in 12 to 1 part in 2,240 parts of soil.

The results indicated that whereas the radio-active materials benefited, more or less, rape, clover, radishes, and lettuce, they had little or no effect upon peas, tomatoes, nasturtiums, and other flowering annuals. Soils treated with black oxid of uranium in the proportion of 1 part in 2,240 of soil appeared, generally, to produce more sturdy plants, but in these cases it was noticeable that the inflorescence was retarded.

The significance of certain food substances for plant growth, W. B. BORTOMLEY (*Ann. Bot. [London]*, 28 (1914), No. 111, pp. 531-539, figs. 2; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 626, I, p. 1208).—A considerable fixation of nitrogen by bacterized peat (E. S. R., 31, p. S21) mixed with soil is reported. Experiments with various plants indicated that a water extract of the peat furnished all the plant food required. The residue from the alcoholic extract of the peat, the phosphotungstic precipitate from the aqueous extract, and the fraction (vitamin) obtained by treatment of the phosphotungstic precipitate with baryta and silver nitrate with the subsequent removal of reagents, exerted a stimulating effect on plant growth. The effect was especially marked in the case of the vitamin.

The author advances the theory "that the nutrition of a plant depends not only upon the supply of mineral food constituents but also upon a supply of certain accessory organic food substances, very small amounts of which are sufficient to supply the needs of the plant. During the early stages of growth of the embryo, these substances are supplied by the seed; later when the young plant is able to maintain itself, they are obtained from the humus of the soil." Further investigations as to the correctness of this theory are stated to be in progress.

The question of fertilizers, L. REBELLO DA SILVA (*Bol. Dir. Geral Agr. [Portugal]*, 11 (1912), No. 11, pp. 64).—The whole subject of sources, value, and use of fertilizers is discussed with particular reference to Portuguese conditions. The restricted use of fertilizers in Portugal as compared with other countries and the very great importance of extending their use in that country are very strongly emphasized.

Utilization with special reference to deriving a financial return from the sewage of New York City, G. A. SOPER ET AL. (*Rpt. Metropol. Sewer. Com. N. Y., 1914*, pp. 341-413).—The report deals especially with sewage farming and with the utilization of sewage sludge. It reviews fully previous investigation and experience and the opinions of authorities in this line throughout the world. The consensus of opinion and experience cited seems to be that the combination of conditions necessary to make sewage farming an efficient means of purification rarely occurs and that, as a rule, the interests of agriculture and of sanitation are opposed.

As regards the utilization of sludge, however, it is concluded that "the revenue to be derived from the sale of dried sludge as fertilizer and from grease will, in many cases, more than offset the cost of production, in large towns, besides furnishing a sanitary and inoffensive method of disposing of sludge. The drying of sludge for fertilizer and the extraction of the contained grease offer a more promising outlook than others. In many works where it would not be worth while to undertake these somewhat elaborate processes, it will be found of advantage to dispose of the semidried, centrifuged, or pressed sludge to farmers for what it will bring or else burn it under the boilers of the plant."

The mechanism of nitrification, E. M. MUMFORD (*Proc. Chem. Soc. London*, 30 (1914), No. 424, p. 36; *abs. in Chem. Abs.*, 9 (1915), No. 4, p. 499).—In a study of the bacterial oxidation of aqueous solutions of ammonium salts on experimental filters inoculated from actively nitrifying sewage filters, it was

found that the oxidation proceeds in a series of stages compatible with the hypothesis that the hydrogen atoms are successively hydroxylated with the subsequent elimination of water. Hydroxylamin salts and salts of hyponitrous and nitrous acids were found as intermediate compounds. "The loss of nitrogen which invariably takes place to a certain extent on such filters is due, in part, to complex interactions between these various intermediate compounds, and as the relative concentration of these compounds is determined by the degree of aeration of the filter, this hypothesis is in correlation with the observed difference in the loss of nitrogen between a percolating filter and a contact bed."

Synthesis of the oxids of nitrogen by the electric arc, E. ROSELIER (*Bul. Assoc. Ingen. Élect. Liège* 13 (1913), pp. 566-646; *Rev. Electrochim. et Electro-met.*, 8 (1914), Nos. 2, pp. 33-50; 4, pp. 97-117, figs. 11; *abs. in Sci. Abs., Sect. B—Elect. Engin.*, 17 (1914), No. 6, p. 305).—A rather full discussion of the theory and processes of electrical fixation of the free nitrogen of the air, especially the oxidation of the nitrogen, is given.

The appliances used and the works in operation are described and the future of the industry is discussed.

When should lime nitrogen be applied to winter grains? P. WAGNER (*Deut. Landw. Presse*, 42 (1915), No. 6, pp. 39, 40).—Experiments are reported which indicate that the best results will be obtained on light well-drained soils by applying the lime nitrogen about the middle of February if the weather conditions are favorable. If the weather is very cold, vegetation backward, or the soil still covered with snow it may be advisable to delay the application from 8 to 14 days. Sodium nitrate apparently gives the best results when applied not earlier than the first of March.

Nitrogenous fertilizers from refuse substances, C. ELSCHNER (*Amer. Fert.*, 42 (1915), No. 5, pp. 21-23, fig. 1).—Methods of preparing available nitrogenous fertilizers from such substances as wool, hair, shoddy, rag, felt, and leather waste are briefly described. The methods are, as a rule, based upon treatment with sulphuric acid, sometimes with the addition of other substances, such as nitrate, to hasten the reduction.

Availability of the nitrogen in Pacific coast kelps, G. R. STEWART (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 1, pp. 21-38).—The availability of the nitrogen of the kelps was measured by its rate of ammonification and nitrification as determined by the so-called beaker method of soil bacteriology. The tests were made with dried and ground kelp.

Ammonification and nitrification of this material in fresh field soil were found to vary with different species and with the manner of preparation. The nitrogen of *Nereocystis lacteana* was found to be relatively very available, while that of *Pelagophycus porra* ammonified and nitrified less readily. The nitrogen of *Macrocystis pyrifera*, which is the variety of greatest commercial importance, changed very slowly in the soil. It was most available when the kelp was added to the soil in a fresh or only partially dried condition and decreased materially when it was fully dried. Removing the salts by leaching did not increase the rate of decomposition.

"The addition of moderate quantities of *Nereocystis* to a sample of fresh soil in the laboratory did not cause any great interference with either ammonification or nitrification of readily available organic matter, such as dried blood. Similar experiments with *Macrocystis* showed at first a decrease in the rate of transformation, especially in nitrification. This decrease did not continue and as time passed the ammonification and nitrification became practically normal."

A bibliography of twenty references to literature bearing on the subject is appended.

The bone, animal waste, phosphate, and phosphorus industries, L. VÉZIEN (*Industries des Os, des Déchets Animaux, des Phosphates, et du Phosphore. Paris: Octave Doin & Sons, 1914, pp. 423, figs. 50*).—This is one of the volumes of the Toulouse Encyclopédie Scientifique. It treats of (1) glue and gelatins, (2) phosphates, and (3) phosphorus. The second part, which is of special interest from the agricultural standpoint, deals with forms of phosphate and the occurrence and mining of phosphate deposits; phosphates of animal origin and their methods of manufacture; and the manufacture of superphosphates.

Analyses of commercial fertilizers, T. F. PECK, J. W. SAMPLE, and A. L. GARRISON (*Tenn. Agr., 4 (1915), No. 2, pp. 59-123, figs. 2*).—Analyses and valuations of 456 samples of commercial fertilizers and fertilizing materials offered for sale in Tennessee during 1914 are reported, with some general notes on the use of fertilizers and the text of the state fertilizer law.

It is stated that the consumption of fertilizers in the State during 1914 was 100,000 tons. Of the total number of brands examined about 60 fell below the guaranty in composition.

Commercial fertilizers, B. H. HITE and F. B. KUNST (*West Virginia Sta. Insp. Bul. 3 (1915), pp. 45*).—This bulletin reports actual and guaranteed analyses of samples of fertilizers offered for sale in West Virginia during 1914. "The inspection work for the past year discloses very few failures on the part of manufacturers to deliver everything that was guaranteed." The economy of purchasing high-grade fertilizers is urged. "Purchasers of fertilizers are advised not to invest in fertilizers in which the sum total of the available phosphoric acid, potash, and nitrogen is less than 14 per cent. In the case of ground bone, the nitrogen and phosphoric acid (together) should be at least 24 per cent."

AGRICULTURAL BOTANY.

On certain relations between the plant and its physical environment, J. B. FARMER (*Jour. Roy. Hort. Soc., 40 (1914), No. 2, pp. 197-207, pls. 4*).—This article deals with the plant in its relation with its physical environment, considering such factors as moisture, temperature, illumination, nutriment, and response, rather indicating the problems which are becoming evident than giving the results of investigations carried out.

The general conclusion arrived at is that the more closely we are enabled to analyze the response of a plant to the demands of its physical environment, the more we find that such laws as are known of chemistry, molecular physics, surface tension, etc., hold good and serve as guides to investigation. Even autoregulation seems (at least in some critical instances) to be explicable as the result of limiting factors not essentially different in kind from those which control chemical actions in vitro. In these directions, it is thought, lies our hope of gaining control over vital processes.

The plant in relation to its biological environment, J. B. FARMER (*Jour. Roy. Hort. Soc., 40 (1914), No. 2, pp. 208-214*).—This deals with the influence of such biological factors as competition (in relation to chemical processes or properties), symbiosis, chemical products favorable to certain successions, parasitism and its modifying effect on hosts, submission or resistance to chemotaxis, and the relation of form to composition.

Town smoke and plant growth, C. CROWTHER and A. G. RUSTON (*Jour. Agr. Sci. [England], 6 (1914), No. 4, pp. 387-394, figs. 3*).—Having followed up previous investigations (E. S. R., 25, p. 434), with attempts to measure directly the inhibiting effects of atmospheric pollution upon plant growth in the city of Leeds and vicinity, the authors state that while of the disturbing fac-

tors, soil differences, altitude, exposure, etc., they were able to eliminate only the first mentioned, still the differences in plant development (corresponding to changes in atmospheric content) at the several stations in different directions and at increasing distances from the main center of pollution are so definite as to leave little doubt that the dominant factor therein is the varying quality of the atmosphere.

On damage caused to vegetation by sulphurous and sulphuric acids in the atmosphere, R. R. TATLOCK and R. T. THOMSON (*Analyst*, 39 (1914), No. 458, pp. 203-210).—Giving the results of observations and analyses of different portions of several plants and of soils in different localities, the authors reach the conclusion that the atmosphere even of cities consuming large quantities of coal is acid only under very exceptional circumstances, and even then within narrow limits. Injurious effects, when present, are strictly local, neither acidity nor damage being perceptible in cases where the acid has been dispersed through a large volume of surrounding air.

Hail injury to cereals, R. SCHANDER (*Fühling's Landw. Ztg.*, 63 (1914), No. 21-22, pp. 657-703, figs. 12).—Giving details and conclusions of a study of hail injury to rye, wheat, barley, and oats, as regards the different parts and stages, the author claims to have shown that certain forms of such injury may be both qualitatively and quantitatively estimated by methods here exemplified.

Transpiration and the ascent of sap in plants, H. H. DIXON (*London: Macmillan & Co.*, 1914, pp. VIII+216, figs. 30).—The author offers an explanation of the ascent of sap in plants, based very largely on physical properties of liquids.

The transpiration stream, it is claimed, is raised by secretory actions taking place in the leaf cells, or by evaporation and capillarity. The author maintains that structural and physiological evidence prevents the acceptance of the physical or vital theories, as the same configuration, physical properties, and structure of the wood indicate that water in the conducting tracts not acted upon by force behind must pass into a state of tension. Therefore when root pressure is not acting and when the leaves of trees are transpiring, the cohesion of their sap explains fully the transmission of the tension downward, and consequently explains the rise of sap. In order to raise the transpiration stream 100 meters in height a tension of 20 atmospheres would be required. Studies of cohesion of sap indicate that it amounts to at least 200 atmospheres, and consequently would be in no way overtaxed by this tension. The determination of the osmotic pressure of sap has been shown to be adequate to resist transpiration tension. Other factors, however, are said to enter in, and the pressures developed are much in excess of those demanded by transpiration. It is claimed that the stored energy set free by transpiration in leaves is quite sufficient to do the work of secretion against the resistance of the transpiration stream.

Extreme alterations of permeability without injury, W. J. V. OSTERHOUT (*Bot. Gaz.*, 59 (1915), No. 3, pp. 242-253, figs. 4).—As some investigators have claimed that permeability is a relatively fixed property of cells while others assume that there are reversible changes, the author has undertaken a series of experiments with living tissues of *Laminaria saccharina*, determining the permeability of the cells by their electrical resistance.

The results obtained by the use of quantitative methods indicate that the permeability of protoplasm may be greatly increased or diminished without injury. A rapid alternation of increase and decrease did not produce injury.

The problem of food movement in trees, S. B. ELLIOTT (*Forestry Quart.*, 12 (1914), No. 4, pp. 559-561, figs. 2).—An account is given of a young white

pine which had been girdled at least five years previously by some rodent. It had continued to live, growing above (not below) the decorticated portion, but apparently only between the first and second whorl of branches, the first of which was just above the injured region which had been denuded of bark, cambium, and some of the outer sapwood. The circumstances are held to show that mineral food must have passed from the roots to the leaves and that material was practically prevented from passing down from the leaves to the roots, but no complete explanation is yet evident for the nonincrease in size of the portion between the second and the third whorl of branches.

A second case is noted of a white pine, originally a forked tree, in which natural grafting between the two forks has taken place in three or four places. One stem has been separated below but continues to grow, the crown now being more vigorous and thrifty than that of the rooted member. The taper of the severed tree has been altered and is now considerably less than that of the other. An important feature is the continued healthy growth of the severed stem below the graft and the more rapid increase at the junction end of the trunk than at the severed end. The upper end apparently permits only such food as its needs do not require to pass downward to the lower portion of the severed trunk, which has no roots, live limbs, or leaves.

The influence of chlorids and nitrates of potassium and sodium on germinating plants, H. MICHEELS (*Internat. Ztschr. Phys. Chem. Biol.*, 1 (1914), No. 5-6, pp. 412-419).—Studies were carried out regarding the effects on percentage of germination, length of first leaf, length of root, and weight of the plantlet in case of wheat grown in solutions of potassium chlorid, potassium nitrate, sodium chlorid, and sodium nitrate, which show almost the same degree of dissociation at the two concentrations employed ($\frac{1}{100}$ and $\frac{1}{1000}$ normal).

In solutions uninfluenced by the presence of an electrical current the chlorin ion was more harmful than the nitric acid ion and the sodium more so than the potassium ion. The nitric acid ion acts favorably on leaf length, plant weight, and length of root hairs, but this is not true of the chlorin ion. While sodium is more harmful than potassium, it gives greater root length. The same general results were obtained during electrolysis of the solutions. The differences observed are ascribed to physiological properties of the same ions and not to any chemical properties.

A method of prophesying the life duration of seeds, W. CROCKER and J. F. GROVES (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 3, pp. 152-155).—This article gives a detailed account of investigations previously noted (*E. S. R.*, 32, p. 221), in which the authors claim that gradual loss of viability in seeds during storage is due to a slow coagulation of the proteins in the plasma of the embryo. They have found in experiments a rather close agreement between calculated and found values, which indicate that a time-temperature formula for the coagulation of proteins can be applied as a temperature-life duration formula for seeds, at least under the conditions of these experiments.

Light and the rate of growth in plants, D. T. MACDOUGAL (*Science*, n. ser., 41 (1915), No. 1056, pp. 467-469).—Attention is called to a statement by the author (*E. S. R.*, 15, p. 339) in which it was shown that light has no invariable or universal relation to growth in plants. In the present paper additional data are presented to substantiate this claim. The investigations of Richards and Spoehr on the growth, hydration, and acidity in certain species of *Opuntia* (*E. S. R.*, 30, pp. 429, 431) are said to have a bearing on this problem.

The results of an extended series of observations on *O. Blakeana* are given, which are said to show that the growth of the enlarging joints is at a minimum in the morning, with a rapid acceleration parallel with the rising temperature of the open, reaching a maximum about noon and then decreasing to a

minimum before 3 o'clock. The growth of the opuntias takes place during a period of decreasing acidity, resulting from the disintegrating action of light and rising temperatures. This statement, it is believed, applies not only to the diurnal behavior of the plants during the growing season, but to the growing season as a whole.

In conclusion the author states that light and temperature in lesser degree are seen to exercise a totalized releasing effect on growth coincident with reduced acidity and increased hydration to a certain limit. Beyond this growth is checked.

The time and distance relation between brief illumination and reaction in sprouting vetches, G. CAMPANILE (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 23 (1914), I, No. 12, pp. 966-969).—This gives in tabular form the responses by sprouting vetches after an exposure of one second to a light of 50 candlepower at distances of 1 to 4 meters. Distance does not appear to affect the degree of curvature, but the percentage of perceptible responses increases with the time from zero at all distances employed for half an hour to 58, 25, 22, and 14 per cent at 1, 2, 3, and 4 meters, respectively, for 2½ hours, and 100, 98, 82, and 70 at these distances for 10 hours.

On the identity of heliotropism in animals and plants, J. LOEB and H. WASTENEYS (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 1, pp. 44-47).—Attention is called to the fact that the investigations of Blaauw (*E. S. R.*, 22, p. 329) showed that the time required to bring about the heliotropic curvature of plant changes inversely with the intensity of illumination, and that the same law holds for the heliotropic curvature of the polyyps of *Eudendrium*.

Some further investigations have been conducted to compare the relative efficiency of the various parts of the spectrum upon the production of heliotropic curvatures in *Eudendrium* with that found for the heliotropic curvatures in plants. These showed that the relative efficiency of the different parts of the spectrum of a carbon arc light for the production of heliotropic curvatures in *Eudendrium* and in seedlings of *Avena* is practically identical.

The coefficient of mutation in *Oenothera biennis*, H. DEVRIES (*Bot. Gaz.*, 59 (1915), No. 3, pp. 169-196).—The author gives the results of a study of about 8,500 individuals grown from seeds taken from pure line pedigreed plants of *O. biennis*.

There were found among these specimens 8 *naucella*, 4 *semigigas*, and 27 *sulfurea* mutants, giving percentages of about 0.1, 0.05, and 0.3 per cent. The origin of mutants from other species, the question of partial sterility, and other mutation factors are discussed at some length. The author considers the phenomenon of mutability observed in *O. lamarckiana*, *O. biennis*, and allied forms, as a simple continuance of the supposed mutability which presided at the origin of the wild species of the evening primroses.

In connection with his investigations, it was found that the seeds of evening primroses were often very slow in germinating. This difficulty, it is said, can be overcome by pressing water into them, a pressure of 6 to 8 atmospheres for from 1 to 3 days being sufficient to stimulate all to a rapid germination.

An interpretation of self-sterility, E. M. EAST (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 2, pp. 95-100).—The author offers a suggestion as to the cause of sterility based upon a study of descendants of a cross between *Nicotiana forgetiana* and the large white-flowered variety commonly known as *N. affinis*. A large number of experiments in which plants were self-crossed and back-crossed through several generations were made and studies were conducted with pairs of plants which furnished series of selfed and crossed flowers. In these the pistils were examined at regular periods and the difference between the development of the pollen tubes in the selfed and crossed styles was found

to be wholly one of rate of growth. In the selfed pistils the pollen tubes developed steadily at a rate of about 3 mm. in 24 hours. Since the maximum life of the flower was found to be about 11 days, the tubes were never able to traverse more than one-half the distance to the ovary. On the other hand, the tubes in the crossed pistils, though starting to grow at the same rate as the other, pass down the style and reach the ovary in 4 days or less.

From these facts it is concluded that the secretions in the style stimulate the pollen tubes from other plants instead of inhibiting the tubes produced by pollen grains from the same plant. It is believed that there are present on the style stimulants, and experiments indicate that the principal one is a sugar, probably of the hexose group. In the pollen grains there is considered to be a specific material in the nature of an enzym which calls forth secretion of the sugar that gives the direct stimulus.

Further observations on the relationship between the number of ovules formed and the number of seeds developing in *Cercis*, J. A. HARRIS (*Bul. Torrey Bot. Club*, 41 (1914), No. 11, pp. 533-549, figs. 4).—In a previous paper (*E. S. R.*, 31, p. 523), the author discussed the relationship between the number of seeds maturing and the number of ovules formed in the pods of a series of trees of *C. canadensis* from different habitats.

In the present paper an account is given of collections made from individual trees, in which it appears that the physical constants, type, variability, and correlation of the number of ovules per pod and the number of seeds developing per pod in *C. canadensis* differ sensibly from individual to individual and from habitat to habitat. The data do not, however, justify the conclusion that trees from different habitats may be distinguished taxonomically. The correlations for number of ovules formed and number of seeds developed per pod have always been found positive and of a moderate, considerable, or even high intensity. The correlation coefficient is said to be slightly raised by the combination of collections from different individuals.

The taxonomic value of pore characters in the grass and sedge rusts, J. C. ARTHUR and F. D. FROMME (*Mycologia*, 7 (1915), No. 1, pp. 28-33, fig. 1).—It is stated that there are at present known in North America 105 species of rusts on grasses and 40 on sedges having urediniospore-pore characters that are clearly distinguishable, and hence available for use in their possible application to taxonomic study. Three general types of distribution of the pores are recognized, namely, scattered, equatorial, and extraequatorial. It is thought that the practical importance of pore characters of the urediniospores of the grasses and sedge rusts lies in the application of this knowledge to the identification of the material that is incomplete. It has already been possible to make some progress in determining the species of rusts from urediniosporic material alone.

The development of *Armillaria mellea*, G. F. ATKINSON (*Mycol. Centbl.*, 4 (1914), No. 3, pp. 113-121, pls. 2).—This is an account of the progress of differentiation in *A. mellea*. The view is expressed that the zone of radial hyphae, and a part at least of the cortical zone of the young carpophore of *A. mellea*, is homologous with the radial and cortical zone in *Lepiota clypeolaria*. It is thus homologous with the universal veil in certain species of *Amanita* and *Amanitopsis*, but does not become differentiated from the pileus as it does in these two genera.

FIELD CROPS.

Report on the experimental work of the Palur agricultural station for 1913-14, G. D. MEIITA (*Dept. Agr. Madras Rpt. 1913-14*, pp. 21).—The variety tests here reported include peanuts, sugar cane, and rice grown on irrigated

land, dry land, and wet land. Rotation experiments on these lands include peanuts, cotton, "tenai" (*Setaria italica*), "cumbu" (*Pennisetum typhoid-eum*), and "ragi" (*Eleusine coracana*).

Results covering a period of seven years show that growing a cereal with peanuts gave an increased net profit per acre, although the yield of peanuts was less than when that crop was grown alone. Manurial tests included bone meal, burnt shell lime, powdered shell, peanut stalks, shells, and cake, and pit manure. Using a green manure crop, "daincha" (*Secbania aculeata*), in the production of rice proved very beneficial.

A handbook of Nebraska grasses, E. M. WILCOX, G. K. K. LINK, and VENUS W. POOL (*Nebraska Sta. Bul. 148 (1915), pp. 5-120, figs. 114*).—Nearly 150 species are identified, and a bibliography of publications of the U. S. Department of Agriculture and the state experiment stations on agrostology is appended.

The Spanish grasses of northern Africa, C. MANETTI (*Agr. Colon. [Italy], 8 (1914), Nos. 9, pp. 553-576, pls. 4, figs. 9; 10, pp. 641-663, pls. 4, figs. 5; 11, pp. 743-763, figs. 10; 12, pp. 815-830, fig. 1*).—This series of articles constitutes a very complete treatise on the Spanish grasses (*Stipa tenacissima*, *Lygeum spartum*, *Ampelodesma mauritanica*, and *Aristida pungens*), covering their cultivation, improvement, uses, and enemies.

Agave.—Its culture and exploitation, F. MICHOTTE (*L'Agave. Culture et Exploitation. Paris: A. Challamel, 1914, pp. 339, figs. 113*).—A treatise containing a study of this plant, its exploitation and culture, the extraction of the fiber, and the utilization of the plant and its products.

First series of researches with reference to red clover breeding, H. M. GMELIN (*Meded. Rijks Hoogere Land, Tuin en Boschbouwseh. [Wageningen], 7 (1914), No. 5, pp. 149-165*).—This describes methods of employing the bumblebee in the seed production of red clover, and gives results of observations upon several varieties of red clover and the effect of different insects upon the fertilization of the flowers.

A genetic and cytological study of certain types of albinism in maize, F. C. MILES (*Jour. Genetics, 4 (1915), No. 3, pp. 193-214, pl. 1, figs. 9*).—This article briefly reviews previous investigations along this line, gives results of work conducted at the Nebraska Experiment Station in the inheritance of albinism in maize, and includes an anatomical study of the leaves of certain types of maize.

"From the studies of the various categories it appears that in all cases, with the possible exception of the striped leaves in *Zea japonica*, the several degrees of albinism in corn leaves behave as simple Mendelian recessives; the first generation of a cross with ordinary green races giving fully green plants and the second generation segregating in the ratio of three green plants to one plant of the particular type which was used in the cross. The study of the manner of inheritance of variegated leaves of *Z. japonica* in crosses where aleurone color is involved has not been completed.

"A rather definite relation has been pointed out between a pure white type of maize plant and a yellowish-white type, the results indicating that the presence of at least two factors is necessary for the development of normal green in the leaves of maize. In the absence of one of these factors the plant is pure white and soon dies, while in the absence of the other factor the plant at first is yellowish white but is capable of developing into a greenish condition and sometimes into a pure green plant.

"Studies of the relation between the other categories have not been completed. Crosses of striped plants of the japonica type with golden plants, and

those of the green striped plants with golden plants and also the crosses of green striped plants with yellowish-white individuals which turn green, have all resulted in first generation plants which were of the normal green color. Although it was impossible to note the second generation plants, except during the first five weeks of their growth, it was possible at that time to identify segregates of the respective categories. The results secured in these crosses, however, add further evidence to the hypothesis that more than one factor is concerned in the production of normal green color in the leaves of maize. Apparently there is lacking in each parent some genetic factor (or factors perhaps) which is concerned in the development of chlorophyll, and, since the F_1 plants are normal green, it appears as if that factor which is lacking in one parent may be present in the other.

"In the pure white plants no plastids could be differentiated. In the yellowish-white plants which later may become green plastids apparently are present from the first, although they are few in number and are very small, gradually increasing in number and size as the leaf turns green.

"In *Z. japonica* the manner of distribution of plastids may be compared with the condition which Trelease has described in certain variegated agaves. He found that the normal green condition was due to the presence of plastids in the subepidermal region of the leaf. In variegated leaves, if the stripe was pale greenish, there was found to be a suppression of plastids through several of the subepidermal cells, while in a pure white stripe there was 'all but complete suppression of recognizable plastids.'

Perjugate cotton hybrids, C. G. MARSHALL (*Jour. Heredity*, 6 (1915), No. 2, pp. 57-64, figs. 5).—This article notes the great diversity of characters that appeared in the perjugate, or second generation, while the individuals of the conjugate, or first generation, resulting from a cross between Hindi and Egyptian cotton were very uniform and showed characters intermediate between the two parents.

It is noted that "studies of the different parts of the several plants, such as the leaves, involueral bracts, bolls and seeds, revealed as great diversity and range of differences among these more detailed characters as there was in the general appearance and habit of growth of the plants. . . . The leaves of the different plants varied in color from a light or yellowish green to a very dark green, some of the plants showing a bronze or reddish tinge. They also varied in shape from simple leaves to leaves with deeply cut lobes, with margins wavy or crenate in many different degrees. There was the same variation in the glossy or hairy surfaces, as well as in texture and veining; in fact, the leaves of sister plants were often so different that they might well have represented as many distinct types of cotton. . . .

"The extra floral nectaries, which are one of the specialized features of the cotton plant, also showed many aberrations and sometimes marked degeneration. The general tendency seemed to be toward a smaller development of nectaries than in the parent stocks. On the majority of the plants the nectaries both of the leaves and involucre were very small and inactive or altogether absent. . . .

"The bolls of these perjugate hybrids were perhaps more striking in their diversity and possession of strange characters than any other parts of the plant. There were many shapes, some very unusual and freakish. The bolls of one plant were very long and narrow, almost cigar-shaped. Another plant had bolls almost round but with a beak as long as, and in many cases longer than, the body of the boll. Still another plant had small bolls with blunt ends and a constriction at the middle which made them look like peanuts. Some plants had large bolls and some small, some had bolls dotted with numerous oil

glands and some with few; some plants had bolls deeply pitted and some had bolls with smooth surfaces, the oil glands being more deeply buried in the tissues of the wall.

"The seed and lint characters were as diverse as the boll characters. The seeds from the different plants were of many sizes and shapes and no two plants showed the same distribution of fuzz on the seed. The seed of one hybrid plant was entirely naked while usually there were tufts of fuzz at either the apex or base of the seed or at both ends, these tufts varying in size for the different plants. Several plants had the seeds completely covered with thick fuzz, but even these differed from each other in that some had green fuzz, some brown, and some pure white. The lint also varied greatly in both quantity and quality and ranged in color from a pure white to a decided buff. From a commercial standpoint the lint would have been of little value because of the variation in length and quality of the lint from the different plants."

Twelve individuals derived from self-fertilized seeds from the same conjugate Hindi \times Egyptian plant are described in detail and serve to show those features in which the plants differ most noticeably from each other and from the parental types.

Relation of density of stand and yield in cotton, A. SHREEDER (*Trk. Turkest. Sclsk. Khoz. Opytn. Stantsii*, 4 (1913); *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 5, pp. 522, 523).—Observations of the author indicate a ratio existing between the soil surface occupied by the cotton plant and the leaf surface of that plant. This ratio is unaffected by the thickness of planting, and the soil condition seems to be the chief factor in determining it. The number of bolls on each plant was found to be approximately proportional to the distance between each plant, and it is noted that the number of maturing bolls was found to depend on the number of stems per unit area and not on the total number of ovaries.

Close planting of cotton to avoid frost injuries, R. SHREEDER (*Turkest. Sclsk. Khoz.*, No. 2 (1913); *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 5, pp. 518, 519).—This notes the success of close planting as a means of securing early maturity of the bolls to avoid injuries by early frosts.

Flax culture, V. E. FREEMAN (*New York: Author, 1915, pp. 19, figs. 9*).—This book treats of the preparation and industrial use of the flax plant in its various phases.

Germination of hemp seed, G. CONSOLANI (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 6, pp. 427-430, figs. 2).—This article gives results of germination tests in 1914 of hemp seeds grown in the years 1909-1913. The percentages of germination were 60, 0, 71, 65, and 79, respectively. With the 1909 seeds the plumules did not appear until the ninth day and germination continued until the twenty-first day, while with the 1913 seeds the plumules appeared on the sixth day and germination was ended by the sixteenth day.

Experiments on lime requirements of lupines, VON SEELHORST, GEILMANN, and R. THIELE (*Deut. Landw. Presse*, 42 (1915), No. 1, pp. 3, 4, figs. 2).—This article reviews previous work of investigators, and gives results of pot experiments conducted at Göttingen to determine the influence of applications of lime on the nodule development and consequent growth of the plants. Half of the pots were filled with sterilized soil, and these soils were then inoculated by means of soil known to contain the proper nodule-forming bacteria and that had been variously treated with lime, sodium nitrate, and ammonium sulphate.

Tabulated data show that the maximum development of nodules was produced with the untreated inoculating soil or that containing small quantities of lime or nitrate of soda. The combined applications of small or large quantities of

lime, sodium nitrate, or ammonium sulphate seemed to check their development. The authors conclude, therefore, that the injurious effect of lime applied to lupines is due directly to the unfavorable soil conditions thus produced for the development of the nodule-forming bacteria.

Yields of native prickly pear in southern Texas, D. GRIFFITHS (U. S. Dept. Agr. Bul. 208 (1915), pp. 11, pls. 2).—This bulletin reports work in continuation of that previously noted (E. S. R., 20, p. 34), but includes the additional species *Opuntia gommei* and *O. cyanella* and some other less important species. Methods of cultivation employed at Brownsville and San Antonio, Tex., and at Chico, Cal., are described.

The yields at Brownsville were at the rate of from 35.492 tons to 185.837 tons per acre for 2- and 3-year-old plants, making an annual production of from 17.746 to 54.703 tons of succulent feed per acre. These yields were from newly planted cuttings. Yields of stumps from which a crop had been harvested often averaged over 100 tons per acre per year. The yields from cuttings at San Antonio ranged from 2.83 to 20.685 tons per acre, and from stumps from 9.8 to 28 tons per acre.

It is noted that shallow cultivation to suppress weeds gave better results than deep cultivation or a dust mulch system. Thorough preparation of the soil before setting the cuttings seems essential for the best results.

Report of the prickly pear traveling commission, November 1, 1912, to April 30, 1914, T. H. JOHNSTON and H. TRYON (Rpt. Prickly Pear Travel. Com., Queensland, 1912-1914, pp. XX+131, pls. 28).—The report of a commission of inquiry appointed by the Queensland Government to visit countries in which prickly pear plants are indigenous or have become naturalized, for the purpose of ascertaining what diseases, parasitic plant organisms, and parasitic or predatory insects are injurious to these plants, as a method of destroying or controlling their growth, and also the possibility of utilizing prickly pears for commercial purposes. The results of these studies of the activities of rodents, insects, and diseases; the utilization as food for man and for stock, as a fertilizer, and as a source of alcohol, fiber, and oxalic acid, and the utilization of the mucilage, and coloring matter in the fruit; and the destruction by overgrowth, by chemicals, and by mechanical means are summarized for each of the following countries: Java, Ceylon, India, South Africa, the Canary Islands, Europe, and the Mediterranean area, the United States, Mexico and Central America, the West Indies, South America, the Hawaiian Islands, and the Australian States other than Queensland.

A bibliography of over 400 titles is appended.

On the inbreeding of rye, K. VON RÜMCKER and R. LEIDNER (Ztschr. Pflanzenzücht., 2 (1914), No. 4, pp. 429-444, figs. 4).—This article discusses data obtained in experiments previously noted (E. S. R., 21, p. 736; 30, p. 525), to study the kernel color of rye in pure lines, and also points out from the same data the increase in yields of progeny of crosses between pure lines of rye.

Physiological studies of *Bacillus radicola* of soy bean, J. K. WILSON (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).—This paper, presented at the ninth annual meeting of the Botanical Society of America, Philadelphia, in December, 1914, "confirms earlier work as regards the influence of nitrates on nodule production, and indicates in addition that sulphates in relatively weak concentration inhibit the process. Chlorids and phosphates stimulate nodule production, while ammonium salts are inhibitory. The significant fact was developed that while nodule development was prevented by the presence of nitrates, phosphates, and ammonium salts, yet the organism retained its vitality in the presence of these salts. Whether the effect of the salt is upon

the root, such as to make it resistant, or upon the organism can not yet be stated."

Can sodium replace potash as a nutrient for sugar beets? KRÜGER (*Deut. Zuckerindus.*, 39 (1914), No. 47, pp. 951-953).—This article describes an experiment in which sodium was applied as a fertilizer in place of potash. The results showed that the sugar and potash contents of the beets followed closely the quantities of potash applied with little reference to the quantities of sodium. The author believes, however, that the presence of the sodium increased the effectiveness of the potash.

Loss in tonnage of sugar beets by drying, H. B. SHAW (*U. S. Dept. Agr. Bul.* 199 (1915), pp. 12, figs. 5).—This bulletin gives results of experiments to determine the amount of loss of sugar beets by evaporation in the field.

The weights of sugar beets pulled at Ogden, Utah, on October 17, 1912, and left spread out, not topped, for 24 hours showed a loss of 10.32 per cent in a mean temperature of 43.29° F. When pulled, topped, and left in rather small piles in a mean temperature of 50° for 3½ hours the roots lost 0.54 per cent in weight. In another similar test in a temperature of 62° for 6½ hours the roots lost 2.42 per cent in weight.

In a test at Garden City, Kans., in which the roots were placed in medium-sized piles and left exposed from November 10 to November 14, there was a mean daily loss of 6.48 per cent in weight. A similar experiment in which the roots were thrown into large piles (500 lbs.) showed a total loss when covered with the beet tops of 4.18 per cent in one series and 4.85 per cent in another. When left exposed the losses were 15.06 and 14.14 per cent, respectively.

In testing the effect of drying upon the sugar content of beets laboratory results showed that the percentage of sucrose increases as the water is withdrawn by evaporation. It was also shown that some inversion and decomposition take place even during so short a period as about 30 hours.

Beets in large open piles containing 11 tons 900 lbs., 16 tons 1,700 lbs., and 28 tons 190 lbs., respectively, and left from November 3, 1912, to January 4, 1913, lost 4.1 per cent in weight during the two months. The mean temperature was 36.72°.

The relation of shrinkage to money loss is discussed.

Variation in the content of sugar in beets during the second year, O. MUNERATI, G. MEZZADROLI, and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 5, pp. 317-336, figs. 6).—This article gives results of a study to determine the variation of sugar in beets during their seed-producing period. Beets were analyzed in March, 1913, at the time of transplanting and again at different dates in September, October, and December, just before, during, and after the maturation of the seeds.

The tabulated data show a wide variation in the content of individual beets and that many had a relatively high sugar content at the end of the season, even higher in some cases than before the growth of the seed stalk; that there is a class of roots that nearly maintains its quality, form, and weight; that there is another class that substantially changes in quality and increases more or less in weight by new growth; and that there is an intermediate class.

Contribution on the biology and valuation of beet seeds, M. PLAUT (*Jahresber. Ver. Angew. Bot.*, 11 (1913), No. 2, pp. 168-217).—This article reviews work of previous investigators, and gives results of work performed at the experiment station at Hohenheim, Germany, respecting methods of sampling, testing, and estimating the agricultural values of beet seeds. The method of sampling that proved to be the most exact is that termed the "count-percentage method" (Zählprozentmethode), with modifications in averaging originally

used by the author. The comparative exactness of the three methods, actual count, count-percentage method, and count-percentage method with averages are indicated as 58:37:25.

As a measure of the agricultural value of beet seeds the author tried several methods of weighing 100 germinating seeds within definite periods. This proved satisfactory, as this weight bore a direct relation to the vigor of the germ.

Results of work in breeding and selection and of observations on variability and the correlation of variability with sugar cane, carried on at the sugar factory at Sempalwadak, Java. R. A. QUINTUS (*Arch. Suikerindus. Nederland. Indië*, 22 (1914), No. 39-40, pp. 1369-1495, pls. 22).—The work here reported was carried on in 1911, 1912, and 1913. The studies were made in regard to heredity as influenced by selection in both sexual and vegetative methods of propagation with pure lines and hybrids of sugar cane. Variability and the correlation of variability in regard to the production of the crops are discussed.

The author concludes that with self-fertilized sugar cane the inheritance of characters follows closely Galton's law of regression. Deviations either within pure lines or in hybridization do not seem to be inherited. In hybridizing it appears that the individual parental characters follow Mendel's law in the second generation. Some characteristics such as thickness, tillering, and sugar content do not seem to be inherited. There is a negative correlation between cane weight and percentage of sugar in the juice, and a positive correlation between the cane weight and sugar yield.

The structure of the stomata of the sugar cane, J. KUYPER (*Meded. Proefstat. Java-Suikerindus.*, 5 (1914), No. 1, pp. 12, pls. 2, fig. 1; *Arch. Suikerindus. Nederland. Indië*, 22 (1914), No. 47, pp. 1679-1690, pls. 2, fig. 1).—This article gives results of microscopical examinations of the parts of the stomata, including guard cells, accessory cells, and the movement mechanism of the stoma cells.

Sugar cane, its cultivation and gul manufacture, J. B. KNIGHT (*Dept. Agr. Bombay Bul.* 61 (1914), pp. 41).—This bulletin discusses the methods of producing sugar cane, including the planting methods known as the Gujārat, Mauritius, Poona, row system, and Java system, and pests and diseases.

Conservation of soil moisture in the cane fields, J. T. CRAWLEY and W. B. CADY (*Porto Rico Bd. Agr. Expt. Sta. Bul.* 8 (1915), pp. 7-9).—This gives the results of a field test in which the soil to the depth of 1 ft. under a 6-in. mulch of cane trash showed a weekly average from September 8, 1913, to June 1, 1914, of 2.2 per cent more moisture than soil which had been cultivated, and 4.1 per cent more than soil that was left fallow, neither cultivated nor mulched.

Stripping of cane, J. T. CRAWLEY (*Porto Rico Bd. Agr. Expt. Sta. Bul.* 8 (1915), pp. 10-16).—This gives results of two seasons' work as to the advantages in stripping the dead leaves and suckers from the growing cane. The averages for the season 1912-13 for stripped and unstripped cane are given as 38.16 and 38.04 tons of cane, 15.44 and 15.46 Brix, 13.23 and 13.19 per cent of sucrose, and 85.6 and 85.3 per cent of purity, respectively. For the season 1913-14 the figures are 20.85 and 21.28, 17.01 and 17.04, 14.86 and 15.06, and 87.4 and 88.3, respectively.

Using cane tops for planting, A. H. ROSENFELD (*Internat. Sugar Jour.*, 17 (1915), No. 193, pp. 16-18).—This article gives results during the first and second years of using the upper third of the stalk for planting, this practice being based on its lesser value as a sugar-producing part. The data show a smaller yield from the cane tops the first year, but there was much less difference the second year between the cane tops and ordinary cane in yield per acre,

and the average weight per stalk was greater than from the ordinary cane, being 1.74 and 1.60 lbs., respectively.

Tobacco mutations, H. K. HAYES (*Jour. Heredity*, 6 (1915), No. 2, pp. 73-78, figs. 2).—This article briefly reviews work with the mutation tobacco known as the Stewart Cuban, already noted (E. S. R., 30, p. 631).

It is stated that on December 28, 1913, seed of this new type was planted in the greenhouse, and transplanted to the field in the spring, where in September the plants had attained a height of from 12 to 14 ft., had produced an average of 80 leaves per plant, and showed no sign of a blossom. They blossomed in October in the greenhouse. The recurrence of other mutants of similar types in several fields in Connecticut is noted and discussed.

Tobacco breeding in Dalmatia, K. PREISSECKER (*Fachl. Mitt. Österr. Tabakregie*, 14 (1914), No. 1-2, pp. 4-48, pls. 3, figs. 11).—This article gives results of hybridization and selection of Dalmatian varieties of tobacco in the experimental fields of Vrlika, Sinj, Imoski, Vinjane, Postranje, and Runovitch, and continues work previously noted (E. S. R., 27, p. 238).

Report of cultural and variety tests with wheat, M. NELSON and L. W. OSBORN (*Arkansas Sta. Bul.* 121 (1915), pp. 3-31).—This bulletin briefly notes the importance and need of improvement of wheat in Arkansas and gives results of cultural and variety tests that were begun in 1907 at the station.

In weekly seedings from the fourth week of September to the first week of November the best average results at Fayetteville, Ark., were obtained from seeding the first part of October. An average difference in yield of 3.61 bu. per acre with three varieties is noted in favor of drilling over broadcasting wheat. The average of the different rates of seeding for the entire test indicates approximately equal yields from either the 4-, 6-, or 8-pk. seedings. Six pk. per acre is the quantity recommended for average conditions. Under the usual conditions shallow (1 in.) covering of the wheat seed was found to be more satisfactory than deep covering.

The number of varieties tested during the several years ranged from 12 to 61 per year. The results indicate that "while the source of seed is not as important as is the type or variety to be chosen, it would seem that preference should be given to home-grown seed, providing a suitable variety can be secured. Varieties obtained from sources having a climate similar to that of Arkansas as a rule have given best satisfaction.

"Results of variety tests indicate that early maturing soft winter varieties yield well and produce the best market quality of grain under Arkansas conditions. Red May and Alabama Bluestem are varieties of this type which have proved satisfactory. Fulcaster and Fultz, though somewhat later in time of maturity, have given good results. Other varieties of this same type which have given general satisfaction are Kentucky Bluestem (a white wheat) and Currell Prolific.

"Varieties of hard winter wheat have not produced a uniform quality of market grain, although the yield is frequently high."

A preliminary report of a fertilizer test is also given.

Spring wheat in the Great Plains area: Relation of cultural methods to production, E. C. CHILCOTT, J. S. COLE, and W. W. BURR (*U. S. Dept. Agr. Bul.* 214 (1915), pp. 43, fig. 1).—The study of the yields obtained under various methods of seed bed preparation in the Great Plains region as here presented deals only with spring wheat and is made in such a way as to show the effect of cropping and cultivation in only the year preceding its growth. There is also given a study of the comparative cost of production of wheat under each of the methods studied and the resulting profit or loss.

The work here reported from 14 stations covers an aggregate of 73 station years, embodies the data from a total of 1,683 plat years, and includes parts of ten States. Data for each station regarding yield and cost of production cover the items of fallow, plowing, disking, listing, subsoiling, green manuring, summer tilling, and previous crop.

It is shown that "some seasons are so unfavorable as to result in failure of the spring wheat crop without regard to the cultural methods under investigation. Extremely unfavorable climatic conditions can not be overcome by cultural methods. It is only in those seasons when the rainfall deficit is so small that it can be overcome by moisture stored in the soil that the cultural methods under investigation have shown important effects upon yields. . . .

"Reducing the cost of production has in most cases in these investigations proved a more important factor in determining profits than increasing yields by cultural methods.

"Northern Colorado and Kansas seem from these investigations to be the southern limit of profitable spring wheat production on the Great Plains. This limitation does not apply to winter wheat and other crops under investigation.

"Disked corn ground has given consistently high yields. This, together with the low cost of preparation, has resulted in its showing the highest average profit or lowest average loss of any of the methods tried at all of the 14 stations except one. These profits are based on the assumption that the corn crop was so utilized as to pay for the cost of its production. Furrowing with a lister and leaving the surface ridged through the winter has resulted in a small increase in yield over plowing at seven of the eight stations where it has been tried. As it is a somewhat cheaper method of preparation than plowing, it has consequently been more profitable. The average difference in the yields of spring wheat following fall plowing and spring plowing are very small. At most stations the advantage of one over the other depends upon the season.

"Subsoiling has been of doubtful utility as a means of increasing yields. As a means of overcoming drought it is without value. Summer tillage without crop has given the highest average yields of any method under trial at 12 of the 14 stations. However, on account of its high cost, due to extra labor and alternate year cropping, it has not been the most profitable practice. The most expensive method under trial is green manuring. It has produced less profit or greater loss than any other method under investigation."

Tillering of spring wheat, S. I. VOROBEV (*Bezcncchuk. Selsk. Khoz. Opytn. Stantsiâ, No. 29 (1912), pp. 3; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 4, pp. 405-407*).—This gives the results of experiments conducted in 1912 to study factors influencing the tillering of wheat.

The author concludes that soil fertility, available light, and moisture, as influenced by the spacing of the plants, are the chief determining factors of tillering in the variety studied (Poltavka). In wide spacing the tillering period continued 13 days, while with close spacing no new shoots were sent up after 8 days. It was found that the grain produced on the early appearing tillers was superior to those produced on later tillers. The data are given in tabular form.

Pure seed law, T. P. COOPER (*North Dakota Sta. Rpt. 1914, pt. 1, pp. 14-17*).—This gives results of the examination of 5,577 samples of seeds for purity and germination. Tables show the approximate purity and the number of samples received of a given grade of germination and of hard seed, and the number which contained prohibited seeds.

Pure seed law (Cheyenne, Wyo.: State Dairy, Food, and Oil Comr. [1913], pp. 11).—The text of the Wyoming pure seed law is given.

Weed seeds in farm lands, J. R. FRYER (*Agr. Gaz. Canada, 2 (1915), No. 1, pp. 21-23*).—This article gives results of tests to determine the prevalence of

weed seeds in farm lands and to discover the relation of their prevalence to cultural conditions. Samples of soil were taken from fields in Ontario, Saskatchewan, and Alberta.

The average number of vital seeds per square yard 1 in. deep was found to be in the surface inch 1.107, in the second inch 457, and at from 5 to 7 in. below the surface 331. The average number of vital seeds in 20-oz. samples of sod aged 5 to 10 years was in the first inch 18, in the second inch 14, and at a depth of from 5 to 7 in. 7½. In sod 10 to 15 years old the seeds at the respective depths were 15½, 6, and 3½, and in sod 15 to 20 years old, 20, 2½, and 2½, respectively.

In a field which had grown barley and oats continuously from 1904 to 1912 20 oz. of soil in the surface inch showed 134 weed seeds, the second inch showed 133, and at from 5 to 7 in. 112 seeds were found. A field under a good cropping system since 1905 showed only about one-fourth as many weed seeds as one under continuous grain cropping.

The destruction of weeds by the use of sulphuric acid. E. RABATÉ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 36 (1915), No. 3, pp. 59-67).—This article discusses the work of several years (E. S. R., 30, p. 441) on weed destruction, and gives results of recent trials in which sulphuric acid was successfully used in the destruction of wild mustard, buttercups, shepherd's purse, whitlow grass, wallflower, feverfew, bindweed, knotgrass, trefoil, and *Medicago apiculata* in fields of cereals.

Weeds: How to control them. H. R. COX (*U. S. Dept. Agr. Farmers' Bul.* 660 (1915), pp. 29, figs. 27).—This gives methods of control of weeds and a descriptive list of the 50 worst weeds of the United States.

HORTICULTURE.

Experiments in growing greenhouse crops on muck or humus soils. H. C. THOMPSON (*Jour. Amer. Peat Soc.*, 7 (1914), No. 4, pp. 191-207, figs. 7).—The results are given of experiments conducted by the author during the seasons 1912-13 and 1913-14 to determine the value of muck or humus soils in growing greenhouse crops and the adaptation of different crops to these soils. The work the first season was confined to one representative type of pure muck soil taken from a cultivated field in northern New Jersey and the growing of lettuce, cauliflower, and tomatoes. An additional type of muck from a cultivated field near Kalamazoo, Mich., was used the second season and roses and carnations were also grown on the New Jersey muck. Yields for the various plats are here presented in tabular form and discussed.

No definite conclusions are drawn, but the results for two seasons indicate that a good type of cultivated muck soil is valuable for greenhouse crops. Raw muck soil gave much lower yields than the cultivated soil. The greatest value of muck is for crops grown for their foliage, such as lettuce, although cauliflower and tomatoes produced large yields on pure muck and on mixtures containing from 25 to 75 per cent of muck. Pure muck should not be used with roses, as the foliage growth is too great and the flowers not satisfactory. A mixture of muck soil and clay produced large numbers of flowers of good color with long stems and excellent foliage. With carnations the muck soil did not give as good results as a clay-sand-manure mixture. The flower stems on plants in the plats containing 50 per cent or more of muck were longer and heavier than on the plants in the regular greenhouse soil, but the number of blossoms produced was not as large.

Grafting the eggplant on *Solanum torbum*. H. A. VAN HERMANN (*Modern Cuba*, 3 (1915), No. 3, pp. 54-57, fig. 1).—The author calls attention to the

practice employed at the Cuba Experiment Station of grafting eggplants on a wild species of *Solanum*. This is said to be the only practical way in which eggplants may be grown during the rainy season in Cuba.

Tomatoes for North Dakota, H. O. WERNER (*North Dakota Sta. Bul. 111 (1915)*, pp. 209-232, figs. 3).—This bulletin reports the first season's results of a variety and strain test of tomatoes, in which 87 varieties, comprising 122 strains, were used. Certain cultural tests conducted in connection with the variety tests are also reported, and directions are given for growing and canning tomatoes.

A comparison of the various strains tested showed as great a variation in earliness, total yield, size of fruit, etc., within a variety as between varieties. The plants were grown from seed secured from a number of localities. The more northern grown seed generally gave the best results. It was noticed, however, that in many cases some of the more southern grown seed produced better results, indicating that a northern location can not be substituted for good breeding in tomatoes. The varieties best adapted to the section were the Earliana, Bonny Best, Chalk Jewel, June Pink, and a few other early varieties.

A test of various planting times showed that to secure the maximum crop the seed must be sown late in March, either in the hotbed and then transplanted into pots or cans, or must be sown about the same time directly in the pots, in which the plants may be grown until set in the fields during the latter part of May.

An experiment was conducted in root pruning tomatoes by pulling the plants so as to loosen the main roots and disturb the root system to a considerable extent. This was done on July 23, August 17, and September 1. The results indicate that the roots should not be disturbed too early in the summer, but that when done toward the end of the season the total yield will be increased, as the root injury tends to check vegetative growth and cause the ripening of all fruit that has already been set. Pruning the top appears to stimulate the production of early and large fruit, although the total production may be somewhat decreased.

The pollination and fertilization of fruit trees, E. E. PESCOTT (*Fruit World Austral., 16 (1915)*, No. 2, pp. 33-35).—A brief review of the literature of the subject.

Fruits for Minnesota planting (*Minn. Hort., 43 (1915)*, No. 4, p. 187).—A list is given of orchard and small fruits and nuts adopted by the Minnesota State Horticultural Society in 1914.

An orchard survey of Jefferson County, R. R. JEFFRIES (*West Virginia Sta. Bul. 147 (1914)*, pp. 3-31, pl. 1, figs. 5).—Results are here given of an orchard survey of Jefferson County, W. Va., conducted during the summer of 1913. The survey was limited to orchards over four or five acres in extent and reports were secured on 181 orchards.

The county has approximately 135,524 apple trees, of which 52.3 per cent are of bearing age. The size of the orchards is as high as 320 acres, the typical size being 10 acres. The larger orchards as a rule show a greater yield and income per acre than the smaller orchards. The square system of planting is generally used, the typical distance being 30 by 30 ft. The chief commercial varieties are York Imperial, Ben Davis, Grimes, Arkansas, Stayman Wine-sap, and Winesap. Many of the recent plantings are of Jonathan, Winesap, Delicious, and Gano. Plantings of Ben Davis have decreased during the last few years.

As to soil management the young orchards are generally planted to a hoed or cultivated crop in rotation with a grass or grain crop. Sod culture is generally practiced in bearing orchards, although cultivated orchards are more

profitable. About 30 per cent of the bearing orchards have been in sod for 5 years or more. Sod orchards are pastured chiefly by hogs. Sheep are used to a considerable extent. The data secured indicate that it pays to fertilize orchards and that a combination of manure and commercial fertilizer is the most profitable.

Seventy-five per cent of the orchards are pruned in the spring and annual pruning is practiced in 62.5 per cent.

The chief orchard insect pests are the codling moth and San José scale and the most prevalent diseases are cedar rust and bitter rot. Forty per cent of the orchards are sprayed three times and 10.4 per cent are never sprayed. Lime-sulphur and arsenate of lead is the mixture generally used. Spraying orchards three times produced an average income of \$101.13 per acre. Orchards sprayed twice yielded an increase of \$69.26 per acre, while orchards sprayed once gave practically the same results as unsprayed orchards, viz. \$39.32 for the former and \$39.38 in the latter instance.

Fire pots as a protection against frost, M. B. DAVIS (*Agr. Gaz. Canada*, 2 (1915), No. 1, pp. 9-13, fig. 1).—As the result of a test of fire pots conducted at the Canadian Central Farm with special reference to the protection of vegetables from frost the author concludes that for ordinary purposes, such as a frost of 5 or 6°, 100 heaters per acre are ample to raise the temperature above the danger point. In the test the cost of the heaters and other equipment was \$61 and the operating expenses per acre about \$16.

Some common spray mixtures, O. S. WATKINS (*Illinois Sta. Circ. 160* (1913), 2. ed., rev., pp. 19; (1915), 3. ed., rev., pp. 19).—Revised editions of this circular (E. S. R., 28, p. 48).

To the third edition is added a spraying schedule for Illinois peach orchards, together with the results of some experiments in spraying apple orchards conducted during 1914. These experiments included a test of the efficiency of various brands of arsenate of lead and a test of five and six sprayings of arsenate of lead during the season for the control of the codling moth as compared with the usual four sprayings. The results of the latter test show the beneficial influence of additional spraying in a season when the codling moth is unusually bad. The fruit which received only four sprayings was over 50 per cent wormy, whereas the fruit which received the six sprayings was less than 5 per cent wormy.

Cost of distributing, G. H. POWELL (*Cal. Cult.*, 44 (1915), No. 11, pp. 326-331).—This address, which was delivered before a convention of the Western Fruit Jobbers, comprises a concise survey of the various factors entering into the cost of distributing citrus fruits. The cost data given are based upon investigations conducted under the direction of the California Fruit Growers' Exchange.

The results of this investigation, combining 30 representative markets and including 5,485 reports extending over the year 1914, show that of each dollar paid for oranges and lemons the grower receives 26.7 cts. for the fruit on the tree. The remainder of the dollar is divided as follows: Picking, hauling, and packing, 9.8 cts.; freight and refrigeration 20.5; grower's selling cost 1.5; jobber's distributing cost 8.2; and retail distributing cost 33.3 cts.

[**Papain extraction experiments**], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. [etc.] Antigua, 1913-14*, pp. 18-20).—An experiment was conducted with papaya trees at the Antigua station to secure reliable information relative to the yield of papain per tree and the best method to adopt of drying the product. Data are given showing amount of juice obtained from three trees at various tappings. It was demonstrated early in the experiment that

but little papain can be obtained by bleeding the stems and leaf stalks of papayas.

The data secured deal entirely with the papain obtained from the fruit. Twenty bearing trees yielded 180 oz. of juice from which was obtained approximately 35 oz. of dried papain. It is concluded that under normal circumstances the growing of papayas for the production of papain would be lucrative.

Strawberry growing in Arkansas. W. H. WICKS (*Arkansas Sta. Bul. 122 (1915), pp. 5-48, figs. 22*).—A practical treatise on strawberry culture with special reference to Arkansas conditions, the subject matter being based upon a survey of cultural methods in various districts of the State in 1914.

The phases discussed include soils; location; preparation of soil; varieties; fertilizers; the sex of the strawberry; propagation; setting time and care of plants; system of planting and setting the plants; cultivation, mulching, and picking; practical carriers; packing; marketing; renewing the plants; cost of production; yields; and returns. Information is also given relative to a strawberry grading plan, loading a refrigerator car, by-laws of a fruit growers' association, and instructions to shippers.

Strawberry varieties. O. M. TAYLOR (*New York State Sta. Bul. 401 (1915), pp. 165-192; abridged ed., pp. 8*).—This bulletin comprises a report of varieties of strawberries tested at the station during the past few years. The kinds grown include newer varieties, with standard commercial kinds for purposes of comparison. In addition to a general descriptive list of all varieties showing essentially distinguishing characters, the varieties are listed with reference to blooming season, season of ripening, sex of flowers, plant makers, productiveness, vigor of the plant, resistance to disease, size of the fruit, quality, and desirable kinds.

Strawberry supply and distribution in 1914. W. A. SHERMAN, H. F. WALKER, and O. W. SCHLEUSSNER (*U. S. Dept. Agr. Bul. 237 (1915), pp. 10, pl. 1, fig. 1*).—A statistical review of the strawberry supply and distribution in the United States in 1914, based upon data secured from 466 shipping stations. The information, which is presented in the form of a table, a map, and a chart, shows the number of carloads shipped by States and by shipping districts, and also shows the districts which have overlapping shipping seasons. The data are presented with a view to criticism for the purpose of perfecting methods of securing information of this nature.

Grape culture, with special reference to commercial production under irrigation in eastern Oregon. R. W. ALLEN (*Oregon Sta. Bul. 126 (1915), pp. 3-31, figs. 12*).—This comprises a practical treatise on commercial grape growing, the subject matter being based upon an investigation and study of the grape industry in the Columbia River basin, and of various factors bearing upon the successful development of a commercial industry.

Introductory considerations deal with the present status of the grape industry in eastern Oregon and possibilities of commercial production. Consideration is then given to methods of establishing the vineyard, including descriptions of the more desirable varieties; planting operations; training and pruning; tillage and care of the vines; and harvesting and marketing.

A short bibliography of literature dealing with grapes and grape culture is appended.

Pruning and training young vines. L. RAVAZ (*Prog. Agr. et Vit. (Ed. VEst-Centre), 36 (1915), No. 7, pp. 145-154, figs. 8*).—A popular discussion of methods of pruning and training young vines of *Vitis vinifera*.

Preventable causes of grape loss, F. T. BIOLETTI (*Pacific Rural Press*, 89 (1915), No. 14, p. 421).—A concise summary of causes leading to unsuccessful grape growing with suggestions for their prevention.

The partridge berry (*Vaccinium vitis-idaea*), G. S. TORREY (*St. John's, Newfoundland; Dept. Agr. and Mines*, 1914, pp. 12).—An account of the mountain cranberry with reference to its range, relationship, synonyms, habit of growth, method of fruiting, environment of the plant, soil requirements, insect and fungus enemies, picking and packing, cultivation, and methods of starting a plantation.

Some recent literature on nuts and nut growing (*North. Nut Growers Assoc. Proc.*, 5 (1914), pp. 124, 125).—This comprises a short bibliography of literature dealing with different phases of nut culture.

Preliminary report on the Persian walnut, W. C. DEMING (*North. Nut Growers Assoc. Proc.*, 5 (1914), pp. 114-117).—This comprises a preliminary catalogue of bearing Persian walnut trees observed in different sections of the United States and Canada east of the Pacific coast region.

Conifers: Their usages, plantings, and enemies, H. KELLY (*Gard. Chron. of America*, 19 (1915), No. 3, pp. 120-123, figs. 4).—This comprises suggestions relative to the use and care of ornamental conifers, together with a descriptive list of varieties hardy in northern United States.

Tree planting in streets, J. B. FARMER (*Surveyor*, 47 (1915), No. 1208, pp. 380-382).—This comprises suggestions on methods of planting street trees, the subject matter being based primarily on a study of the problem for London streets.

The amateur garden, G. W. CABLE (*New York: Charles Scribner's Sons*, 1914, pp. IX+199, pls. 32).—A popular work on ornamental gardening, the successive chapters of which discuss My Own Acre, The American Garden, Where to Plan What, The Cottage Gardens of Northampton, The Private Garden's Public Value, and The Midwinter Gardens of New Orleans.

The development of orchid cultivation and its bearing upon evolutionary theories, J. CONSTANTIN (*Scientia*, 10 (1911), No. XIX+3, pp. 84-100; *Ann. Rpt. Smithsn. Inst.*, 1913, pp. 345-358).—The author gives a résumé of the cultural technique which has been evolved in growing and breeding orchids of various species, and advances the opinion that Mendelian laws do not seem applicable to cases of two parent species of an offspring differing from each other by numerous characters. The evidence deduced from the development of orchid culture indicates that new characters may be brought about through exterior influences.

FORESTRY.

Some observations on the variation in length of coniferous fibers, H. B. SHEPARD and I. W. BAILEY (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 4, pp. 522-527, fig. 1).—The authors have studied the stems of *Pinus strobus*, *P. palustris*, *Picea rubens*, *Tsuga canadensis*, and *Abies concolor* with reference to the variation in length of tracheids in succeeding rings of the cross sections of stems; the variation in length of the tracheids of an annual ring at various heights in the stem; and the influence of the width of annual rings and "rottholz" or compression wood upon the length of tracheids. The results are here presented in tabular form and summarized.

Attention is called to the fact that fiber length varies to a marked degree in different parts of the plant, hence the average fiber length for a given region of the tree is not representative of a species. Since the fiber length in young

and old wood may also vary considerably, it is concluded that average fiber lengths are of relative value, and often of doubtful significance for the purpose of identifying woods of economic importance.

Seed production of western white pine, R. ZON (*U. S. Dept. Agr. Bul. 210 (1915), pp. 15*).—In this paper the author points out different problems involved in determining forest seed production, describes a method of measuring the seed crop as applied in 1911 to the study of seed-bearing characteristics of the western white pine in Idaho on the Kaniuku and Cœur d'Alene National Forests, and presents the results of this study in tabular form.

Although no final conclusions are drawn from the data secured, some deductions have been made chiefly to point out the still unknown factors involved in the problem of seed production and to demonstrate the suitability of the described method for solving them.

Ash in North Carolina, W. D. STERRETT (*N. C. Geol. and Econ. Survey, Bien. Rpt. State Geol., 1913-14, pp. 77-83*).—This comprises a short report on a study of the distribution and cut of ash in North Carolina. The six different species of ash occurring in the State are discussed with reference to their silvicultural possibilities and data are given showing the cut of ash by regions, species, and counties in 1910, together with data showing the rate of growth of green ash on typical green ash sites in North Carolina and South Carolina, and of white ash growing under favorable conditions in New York. A table is also given showing the yield possibilities of pure, even-aged, well-stocked stands of ash such as could be grown under management on different qualities of locality.

The forests of Chile, F. ALBERT (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 12, pp. 1535-1541*).—A short descriptive account of the forest regions and trees of Chile.

Fifth biennial report of the state forester of the State of California, G. M. HOMANS (*Bien. Rpt. State Forester Cal., 5 (1913-14), pp. 202, pls. 2, figs. 32*).—In addition to a review of forest activities in the State during the biennial period 1913-14, this report is chiefly directed toward the support of the principle of initiating a state forest protective system. It presents arguments, endorsements, and data as to legislative measures operative in other States having special bearing on forest protection.

[Report on Indiana Forest Reserve for 1914] (*Ann. Rpt. Ind. Bd. Forestry, 14 (1914), pp. 17-34, figs. 4*).—This report comprises a brief description of the reserve; a record of several newly planted tracts, including cost data; brief notes on forest cleaning, insect damage, and forest fires; rainfall data; and a progress report on previously planted forest tracts.

Eleventh annual report of the state forester of Massachusetts, F. W. RANE (*Ann. Rpt. State Forester Mass., 11 (1914), pp. 111, pls. 8*).—A review of forest activities in Massachusetts during 1914, including the work at the state nurseries and plantations, assistance rendered to woodland owners with special reference to cutting and marketing species subject to moth infestation and reforestation with species immune from moths, forest mapping, fire protection work, suppression of the gipsy and brown-tail moths, parasite work in connection with the control of these moths, assistance in controlling the army worm outbreak, new legislation, and financial statements for the year.

A paper on The Massachusetts State Forest Policy read before the Society for the Promotion of Agricultural Science (*E. S. R., 32, p. 95*) is included.

Forest fires in North Carolina during 1913 and state forest fire prevention in the United States, J. S. HOLMES (*N. C. Geol. and Econ. Survey, Econ. Paper 37 (1914), pp. 75*).—This paper gives a statistical account of forest fires occurring in North Carolina during 1913, shows the inadequacy of the present

forest fire laws of the State, and gives a résumé of state fire protective legislation and activities in the United States.

Annual progress report on forest administration in the Province of Bihar and Orissa for the year 1913-14, with a summary of progress during the five years, 1909-10 to 1913-14, H. CARTER (*Ann. Rpt. Forest Admin. Bihar and Orissa, 1913-14*, pp. VI+60-3, pl. 1).—A report on the administration and management of the state forests in the Province of Bihar and Orissa for the year 1913-14, including a financial statement for the year. All important data relative to alterations in forest areas, forest surveys, working plans, protection, and miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form. A brief summary is also given of progress made during the 5-year period.

Forestry in the British Empire, W. SCHLICH (*Quart. Jour. Forestry, 9 (1915), No. 2. pp. 95-112*).—A paper read at the Forestry Conference of the Anglo-American Exposition, London, July 16, 1914, in which the author sketches the progress of forestry in the United Kingdom and in the various British colonies.

DISEASES OF PLANTS.

Fungus diseases of plants and their treatment, C. O. FARQUHARSON (*Bul. Agr. Dept. South. Prov. Nigeria, No. 2 (1914), pt. 1, pp. 8*).—This, the first of a series, is a very brief and general discussion of fungus diseases and means of protection therefrom in this region.

On the cause of spore formation in rusts, particularly in *Puccinia malvacearum*, L. BLARINGHEM (*Bul. Soc. Bot. France, 61 (1914), No. 1-3, pp. 149-157*).—In continuation of a study on the relation between *P. malvacearum* and its host, *Althaea rosea* (E. S. R., 30, p. 453), the author gives an account of experiments to force the production of spores by the fungus, and the results obtained are believed to have a bearing on spore formation of rusts in general. The conditions for spore formation are said to be external and result from changed osmotic tension of the tissues.

By means of cultures of *Althaea* plants in sugar and salt solutions, dehydration through injury to roots, freezing, etc., it was found possible to break down the symbiosis held to exist between the host and its parasite and to compel the production of spores by the fungus.

Some Scottish rust fungi, M. WILSON (*Jour. Bot. [London], 53 (1915), No. 626, pp. 43-49*).—Notes are given on the occurrence of *Puccinia prostii* on cultivated tulips, *P. borealis* and *P. septentrionalis* on *Thalictrum alpinum*, *P. anthoxanthi* on *Anthoxanthum odoratum*, and *Melampsora alpina* on *Salix herbacea*.

Ustilago, A. POTEENIA (*Iuzh. Russ. Selsk. Khoz. Gaz., No. 45 (1911); abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 3, p. 395*).—The author emphasizes the fact that in combating Ustilago treatment of the seeds with copper sulphate or formalin is ineffective. *U. tritici* and *U. nuda* are best combated by treatment with hot water.

On the propagation of rust in cereals in Sweden and France, L. BLARINGHEM (*Bul. Soc. Bot. France, 61 (1914), No. 1-3, pp. 86-94*).—The author discusses the mycoplasma theory of Eriksson (E. S. R., 14, p. 770) and the more recent publications by Beauverie (E. S. R., 30, p. 241) and others, and gives an account of his investigations since 1912, the previous experiments having been already reported (E. S. R., 31, p. 841). He agrees with Beauverie that the rust pustules on the seed grain have a very important bearing on the distribution of disease in France. Autumnal and early spring infections of *Puc-*

cinia glumarum do not seriously reduce the yield of grain, but where the pustules appear on the stalks and glumes between the period of flowering and maturity there is considerable injury done to the plants.

Report on barley diseases, 1913, J. APPL (In *Bericht über die in den Jahren 1911-1913 durchgeführten Sorten-Anbauversuche mit Gersten [etc.]*. Brünn: Mähr. Landw. Landesversuchsanst., 1913, pp. 39-44, pls. 3).—The year 1913 was particularly favorable to the development and spread of fungus diseases, barley suffering severely in this region, especially from loose smut (*Ustilago hordei nuda*) and stinking smut (*U. hordei tecta*), although the varieties bred by this station were almost entirely free from these diseases.

The report also deals briefly with *Puccinia graminis*, *P. rubigo vera*, *Erysiphe graminis*, *Cladosporium herbarum*, *Helminthosporium gramineum*, *Claviceps purpurea*, and the several fungi noted in connection with foot or stalk disease (*Ophiobolus*, *Leptosphaeria*, etc.), besides some diseases due to animal pests.

Corn stalk and corn root diseases in Iowa, L. H. PAMMEL, CHARLOTTE M. KING, and J. L. SEAL (*Iowa Sta. Circ. 21 (1915)*, pp. 8, figs. 2).—A brief account is given of a new disease of corn found early in the fall of 1914 on an experimental plot. A field study showed it to be present in about 30 localities distributed in 15 counties of the State, reducing the yield in infected fields from 25 to 30 per cent.

The disease attacks roots, stalks, and ears, being easily discoverable by the falling of the corn. This often, however, is attributed to other causes. The stalks usually break near the joints. The diseased stalks have small ears, if any. The pith is frequently destroyed more or less completely, the small axillary shoots are often found to be rotten, and the roots are destroyed so that the stalk pulls up easily.

It has not been determined whether the same organism attacks all parts of the plant. The disease appears to be spread by the mold on the seed corn or on diseased stalks left in the field, and may have existed for some time in the State.

A disease of cattle is ascribed to a fungus found on the stalks. This also is under investigation. The only preventive or remedial measures suggested are rotation of crops and soaking the seed corn in formalin, 1 pint to 45 gal. of water for 15 minutes.

Downy mildew of the cucumber, R. A. JEILLE (*Modern Cuba, 3 (1915)*, No. 2, pp. 33-38, figs. 5).—This is a description, with discussion, of downy mildew (*Plasmopara cubensis*) of cucumbers, which is said to be perennial in Cuba and Florida, and very destructive to melons, cucumbers, and squash, especially during periods of wet weather or heavy dews.

Experiments are referred to which tend to show that Bordeaux mixture sprayed on at intervals during the growing season, preferably just before rains, offers a fair degree of protection.

Bacterial ring rot of potato, A. SPIECKERMANN and P. KOTTHOFF (*Landw. Jahrb., 46 (1914)*, No. 5, pp. 659-732, pls. 7).—The cause of bacterial ring rot of potato plants and tubers is claimed to be *Bacterium sepeдонicum*, a biological and agricultural study of which is reported in some detail. The organism is known to attack, under natural conditions, only *Solanum tuberosum*, though a few inoculations succeeded with four other species of *Solanum*. All other Solanaceae, as well as all other plants, gave negative results.

Destruction of all affected plants is advised.

Powdery scab of the potato, H. C. SANDS (*N. Y. Dept. Agr. Circ. 111 (1914)*, pp. 10, pls. 5).—This is mainly a compilation of information obtained from practical growers regarding the distribution, diagnosis, and treatment of

powdery scab of potatoes, discovered in New York State in June, 1914, and at present thought to be confined to the counties of Franklin and Clinton.

The disease is contrasted with common scab. It seems to be favored by low, wet, alkaline soils and to be made worse by the use of lime.

Field studies of the crown gall of sugar beets, C. O. TOWNSEND (*U. S. Dept. Agr. Bul. 203 (1915), pp. 8, pls. 2, fig. 1*).—The results are given of a study of galls produced on sugar beets, two distinct types being recognized which are caused by bacteria. One of these forms is said to be due to *Bacterium tumefaciens*, while the other is produced by *B. beticola*.

The effect of galls on the sugar content of beets was studied, and it was found that the gall tissue was very low in sugar content and in purity and that therefore their presence is detrimental. Sugar beet galls are said to sometimes cause the beet roots to decay, but so far as general field observations can determine, they do not appear to otherwise affect the tonnage.

The author states that the disease may be held in check by a proper system of rotation with grain crops.

Potato and tomato diseases, E. MOLINAS (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 35 (1914), No. 26, pp. 813-818, figs. 3*).—This is a brief discussion of several potato and tomato diseases of bacterial or fungus causation, and of some preventive or remedial measures recommended.

Wart disease of potatoes, W. CUTHBERTSON (*Gard. Chron., 3. ser., 57 (1915), No. 1469, pp. 97, 98, fig. 1*).—This is a brief historical sketch of potato canker, noting some cases of infection showing the dangerous character of the disease, also some cases of apparent breakdown of resistance, with a list of known resistant varieties recommended for planting on suspected soil. Nearly all of such varieties are white flowered.

Phoma destructiva, the cause of a fruit rot of the tomato, CLARA O. JAMIESON (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 1, pp. 1-20, pls. 8*).—The author reports receipt of specimens of tomatoes affected with fruit rot from Florida in March, 1912, which led to an investigation of the cause of the trouble.

When received, some of the fruit was green, some ripe, and some just beginning to color, but most of the tomatoes had conspicuous dark spots on the side and stem end. A microscopic examination of the tissues showed the presence of a fungus, which has been isolated, and by means of infection experiments the disease has been produced on green and ripe fruit and foliage in the greenhouse and upon tomato plants in the field. Cross inoculations between the tomato fruit and leaf have shown that the trouble was caused in both organs by the same fungus.

Inoculation experiments with the organisms were made on eggplant, potato, sugar beet, Jimson weed, garden pea, bean, and pepper plants, but only on the eggplant and potato were any infections obtained.

A technical description of the fungus causing the disease is given. The fungus has been proved to be an active wound parasite of green and ripe tomato fruit and also capable of causing leaf spotting of tomato and potato plants.

Blue mold in tobacco, T. A. J. SMITH (*Jour. Dept. Agr. Victoria, 12 (1914), No. 11, pp. 641-643*).—The author states that considerable loss is sustained in Victoria by the attacks of the blue mold (*Peronospora hyocynami*) in seed beds.

Accounts of some investigations for the control of this trouble are given, in which formalin, toluol, boiling water, and lime were applied to plats with satisfactory results. All of the seed beds in the experiments were covered

with a coarse bagging, which is considered to be an important factor in controlling temperature and reducing the amount of loss.

A bacterial disease of fruit blossom. B. T. P. BARKER and O. GROVE (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 76-79*).—This is a detailed account of investigations, a preliminary account of which has been noted elsewhere (E. S. R., 32, p. 148).

For several seasons, according to the authors, pear trees have been subject to a disease which is first characterized either by the tips of the sepals turning gray and later blackening, or by the appearance of small black dots on the receptacle of the flower. Occasionally the stigma and style of the pistil of the flower are first attacked, and sometimes the attack occurs on the petals. Occasionally the leaves are attacked, the disease appearing on them in the form of small blackened areas which eventually dry up and fall away.

The organism which is believed to be the cause of this trouble has been isolated and appears to be a species of *Pseudomonas* which has not been identified with any other form previously described. In addition to occurring in pear flowers, it has been isolated from apple, plum, and cherry flowers. Inoculations have been made on young shoots of apples, pears, plums, and gooseberries by means of needle punctures, but without causing any serious injury to the surrounding tissues.

Infection and immunity studies on the apple and pear scab fungi. S. P. WILTSHIRE (*Ann. Appl. Biol., 1 (1915), No. 3-4, pp. 335-359, pls. 4*).—This is a study of the method by which *Venturia inaequalis* and *V. pirina* attack their hosts, and the history of the parasite after penetration, in order to investigate eventually the question of relative immunity.

The facts as noted seem to show that the appressorium penetrates the cuticle, upon which it feeds, and reaches its normal habitat between the cuticle and epidermis, where it flourishes if the attacked variety is susceptible. Immunity apparently does not depend upon any protection afforded by the cuticle, and indications are noted which suggest a general antagonism of the cell sap for the fungus.

Wind scorch of apple foliage. B. T. P. BARKER and C. T. GIMINGHAM (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 67, 68*).—For several seasons attention has been paid to a severe scorching of the foliage of apple trees, and the possibility of the trouble's being due to a fungus or to spray injury was considered.

It was also suggested that wind might be responsible for the trouble by causing a constant rubbing of adjacent leaves on each other, and a careful examination has shown that this is the cause of the injury, the rough edge of one leaf irritating the cells of another at points of contact, finally resulting in the development of a slightly purplish coloration suggesting a slight bruise. Later these discolored patches begin to turn brown, dry up, and present the typical scorched character. It is thought probable that much of the injury that has been attributed to spray mixtures may really be due to the action of wind.

Sources of the early infections of apple bitter rot. J. W. ROBERTS (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 1, pp. 59-64, pl. 1*).—As a result of studies made in the Ozark region of Arkansas, the author has shown that in apple orchards where infections had been severe the fungus *Glomerella cingulata* may winter over on almost any cankered or dead parts of the tree, including the canker due to *Nummularia discreta*, dead tips of fruit spurs, dead parts of limbs due to injury by freezing or to death of roots, branches injured by mechanical means, cankers caused by the pear blight organism, and twig cankers due to *Phyllosticta solitaria*.

The eradication of cankers greatly reduced the number of early infections of the disease, although the removal of all small dead parts, such as the tips of fruit spurs and small mechanically injured places, is not considered practicable.

The natural modes of distribution of pear blight in California, B. J. JONES (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 12, pp. 505-511, figs. 2).—The principal carriers of pear blight discussed are honeybees, flies, ants, pear thrips, apple aphids, some insects living in the soil, of which several are named, and the drip during rains.

Black rot in Spain, L. RAVAZ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 30, pp. 114, 115).—The author reports having found the characters distinctive of black rot on both grapes and leaves of specimens sent for examination from the Province of Valencia, Spain, showing that this region has now been invaded by this disease.

Fungus and other diseases of citrus trees, G. P. DARNELL-SMITH and E. MACKINNON (*Agr. Gaz. N. S. Wales*, 25 (1914), No. 11, pp. 945-954, pls. 4).—In connection with appropriate fungicides and other remedial measures the authors discuss briefly blue mold (*Penicillium* and *Aspergillus*), sooty mold (*Capnodium citricolum*), melanose (*Phomopsis citri* and *Cladosporium brunneo-atrum*), russeting (*Colletotrichum gloeosporioides*), Maori (supposedly physiological), black spot (*Phoma citricarpa*), brown spot (*C. gloeosporioides*), honey fungus (*Armillaria mellea*), collar rot (*Fusarium limonis*), scabbing (*Cladosporium*), withertip and dieback (*Phoma* and *Colletotrichum*), and exanthema and chlorosis (both physiological).

Pseudomonas citri, the cause of citrus canker, CLARA H. HASSE (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 1, pp. 97-100, pls. 2).—During the summer of 1914 diseased material of grapefruit showing the canker was received, and the author presents a preliminary report on the cause of the canker.

A microscopic study of the material showed the presence of bacteria and these were isolated and proved pathogenic to grapefruit seedlings. A study of the organism indicates that it is apparently a new species, and a technical description is given of it under the name *P. citri* n. sp.

A number of investigators have reported the disease due to fungi, and the author states that the open surface of the canker and the spongy character of its structure afford an excellent lodging place for spores of all sorts and that possibly fungi may play a minor part in the later stages of the disease.

Citrus canker in Florida and the Gulf States, H. S. FAWCETT (*Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 12, pp. 512, 513).—This is mainly a summation of information contained in several communications appearing in 1914 regarding the appearance and progress of citrus canker. This has not yet reached California, and it is thought that the drier climate would probably prove unfavorable to its power of destructiveness as shown in the eastern citrus-growing region.

The citrus canker situation in Florida, L. S. TENNY (*Fla. Growers and Shippers League Bul.* 1 (1914), pp. 16).—This is a summary of the papers and discussions presented at the citrus seminar held at Gainesville, Fla., September 22-24, 1914. The speakers discussed the history of citrus canker in Japan and in the United States, the favoring conditions, its appearances, spread, effects, and dangers. The disease infects and matures quickly in warm, wet periods. After infection nothing is known that will prevent the development of the disease, though Bordeaux mixture and corrosive sublimate have been found to prevent infection.

Fungus diseases of limes. J. B. RORER (*Proc. Agr. Soc. Trinidad and Tobago*, 15 (1915), No. 1, pp. 14, 15).—This gives a brief discussion of damping-off in lime seedlings, as preventable by the employment on the seed bed of heat (212° F.) for 20 minutes, or of formaldehyde (4 per cent under confinement for 24 hours), or utilization of subsoil which is sterile, thoroughly disinfected tools, etc. Collar rot and root rot of full-grown lime trees are not very common, but where these diseases appear they are controlled by cutting out the affected tissue.

A preliminary investigation as to the cause of rotting of oranges from Brazil, W. RUSHTON (*Ann. Appl. Biol.*, 1 (1915), No. 3-4, pp. 365-369, fig. 1).—Tests with oranges variously treated before shipment from Brazil to England seemed to show that the best protection is given by wrapping the fruit in thin paper and packing in dry sawdust, also that the worst results follow exposure to moisture and heat. The oranges were attacked by *Penicillium italicum* and some member of the Mucorineae. The changes occurring are described.

Discoloration of tissue precedes the advance of the *Penicillium* in the orange and in orange gelatin cultures. The fungus was not observed to pierce the cuticle, but moisture on the surface probably multiplied the chances of attack through injured cuticle.

Growth of the fungus on cut surfaces was checked by the use of 2 per cent copper sulphate or 5 per cent formalin, but another form of rot appeared after the formalin treatment.

A remedy for the coconut bud rot. J. R. JOHNSON (*Modern Cuba*, 3 (1915), No. 3, pp. 76-80).—The author calls attention to the measures that have been taken in Jamaica and Trinidad for the control of the coconut bud rot, and urges that similar methods be adopted in Cuba to prevent the destruction of coconuts in that island.

Observations on *Rhizina inflata*. J. R. WEIR (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 1, pp. 93-96, pl. 1).—The author states that this fungus is usually found as a saprophyte on burned forest soil, but an attempt has been made to demonstrate its parasitism on certain seedlings.

In 1912 a number of seedlings of pine, hemlock, and larch were observed to be dying, and upon being pulled up the roots were found closely matted together by a white mycelium. Later, near the border of the infected areas and at the base of the stems of the dead seedlings, fruiting bodies of *R. inflata* were observed. An attempt was made to produce the disease by inoculating pine seedlings with spores of the fungus, and, while the experiments were not performed under controlled conditions, the results indicate that *R. inflata* occurs as a parasite in the Northwest.

A new disease of plantation rubber in Malaya. F. T. BROOKS (*Agr. Bul. Fed. Malay States*, 3 (1914), No. 3, pp. 105-107).—The author reports having had under observation for several months a hitherto unrecorded rubber disease in Malaya.

The part of the tree principally affected is the collar, and in this region the bark on one side of the tree dies and the wood beneath it becomes brown. Examination showed the presence of mycelium, and investigations indicated that the fungus is different from the fungi usually reported on rubber trees.

As a result of study the author has come to the conclusion that it is similar to, if not identical with, *Ustilina zonata*. Pure cultures of the fungus have been made and successfully used in inoculating rubber trees, apparently demonstrating that it is the cause of the trouble in question.

It is recommended that all diseased trees be isolated by trenches and cut down and destroyed as soon as they cease to yield latex in paying quantities.

Pink disease, F. T. BROOKS and A. SHARPLES (*Dept. Agr. Fed. Malay States Bul. 21 (1914), pp. 27, pls. 13*).—The present paper embodies the results of an investigation begun early in 1914 regarding the pink disease of rubber trees on Malayan rubber estates, where it has developed considerably since 1912, some estates showing attack in from 10 to 25 per cent of the trees. A preliminary account of this work has already been noted (E. S. R. 32, p. 54).

The causal fungus, *Corticium salmonicolor*, has been known by various names since 1897 and is said to have been found on as many as 141 species of plants distributed among 104 genera and many families. It is supposedly native in most countries where it is found. *Hevea brasiliensis* appears to be the most often attacked of its hosts in Malaya, the chief centers named being at present in the district of heaviest rainfall, where large areas of jungle are still found.

Trees over two years of age are the ones most attacked. Favorite points are the forks, the shady portions of the trunk, and, in general, healthy bark wherever moisture lingers, the attack decreasing in dry weather, with partial or total recovery of the trees. The external manifestations, which may vary considerably, are described, also the effects on the deeper tissues. The spread of the fungus into the trunk affects the water supply, browning and killing the foliage and in the end sometimes the tree. The fungus readily passes from one host to another under favorable conditions in wet weather.

Spraying is impracticable in most cases, owing to the size of the trees affected, the heavy rainfall, and the burrowing habits of the fungus. Precautionary painting of young trees with Bordeaux mixture has been found to reduce the percentage of attack. Estates infected to the extent of 1 per cent would, it is thought, better be dealt with by cutting out or by tarring as directed. When burning is impracticable, infected branches cut away should be disinfected with 10 per cent copper sulphate, then removed and buried. The utmost vigilance is necessary in regions affected.

A study on a "mottled" disease of the black wattle, P. A. VAN DER BYL (*Union So. Africa Dept. Agr. Sci. Bul. 4 (1914), pp. 20, figs. 9*).—Mottling in *Acacia mollissima*, decreasing its tannin content and economic value, is described and discussed in its several aspects and bearings. It is said to be due to physiological derangements caused by unfavorable conditions of growth.

Control of dry rot, MOORMANN (*Gsndhts. Ingen., 37 (1914), No. 28, pp. 533-536, figs. 9*).—Some observations are described to show that *Merulius lacrymans* may be dried out and its activity arrested completely by providing free circulation of air through the spaces beneath floors, etc., within which the fungus otherwise flourishes.

The dry-rot question, R. FALCK (*Gsndhts. Ingen., 37 (1914), No. 51, pp. 846-849, fig. 1*).—This is a discussion, partly critical, supplementing the above report.

Internal therapy of plants, A. DEMENT'EV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 4, pp. 282-293*).—In experiments with plants taking up through cut surfaces salts from solutions under pressures of one to eight atmospheres, and under other conditions, the author found that these substances are taken up at different rates and concentrations, both by the same and different plants, and often in other concentrations than those existing in the solutions offered. He is convinced that these facts may be utilized in combating parasites by a system of internal therapy.

Investigations on Bordeaux mixtures, B. T. P. BAEKER and C. T. GIMINGHAM (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 56-66*).—This is a summary of a number of papers by the same authors, which have been previously noted (E. S. R., 25, p. 458; 31, p. 541; 32, p. 243).

As a result of their observations the authors find that cells with readily permeable walls, such as the germ tubes of fungus spores, root hairs, the interior tissues of leaves, etc., exert a considerable solvent action on the particles of copper compounds with which they may come into contact. There is a rapid absorption of such dissolved copper followed by the death of the cells. The amount of interaction, if any, between other types of cells and the copper compounds is determined by the nature of the cell wall. Direct absorption of copper by leaves of certain types can take place with or without injury, depending on the nature of the leaf surface. Translocation of the absorbed copper to other parts of the plant may follow. Copper may be absorbed through the roots of certain plants, such as potatoes and beans, with local injury to the root. The absorbed copper can be translocated to the aerial parts of the plant without injury to the cells through which it passes.

Burgundy mixture. FONZES-DIACON (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 29, pp. 79-80).—This is a discussion of the composition, application, and action in acid, alkaline, or neutral form of Burgundy mixture designed for use as a fungicide.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Economic zoology report for the year 1913, W. M. ADERS (*Reprint from Zanzibar Protect. Med. and Sanit. Rpt., 1913, pp. 75-102*).—This report deals with entomology in relation to public health and medicine, to veterinary medicine, and to agriculture: birds, beneficial and otherwise; helminthology; blood parasites of mammals, birds, reptiles, and other animals of economic importance; etc.

A pocket list of the mammals of eastern Massachusetts with especial reference to Essex County, C. E. BROWN (*Salem, Mass.: Peabody Academy of Science, 1913, pp. 53, pls. 5*).—This handbook gives brief descriptions of the mammals of eastern Massachusetts, together with notes on their occurrence, habits, etc.

The pocket gopher of the boreal zone on San Jacinto Peak, J. GRINNELL and H. S. SWARTH (*Proc. Cal. Acad. Sci., 4. ser., Zool., 4 (1914), No. 6, pp. 153-159*).—The pocket gopher here dealt with is described as *Thomomys jacinteus* n. sp.

Food habits of the skunk, F. C. PELLETT (*Proc. Iowa Acad. Sci., 20 (1913), pp. 307-309, pl. 1*).—Investigations conducted during a period of five years during which skunks were reared and kept under close observation, lead the author to conclude that the skunk is of considerable value in reducing rodent pests and destroying insects, especially grasshoppers, crickets, and June beetles. Its habit of killing poultry is considered accidental and unusual, and to be confined to a small percentage of the individuals of either the northern plains skunk (*Meophitis hudsonica*) or the little spotted skunk (*Spilogale interrupta*).

The value of birds to man, J. BUCKLAND (*Ann. Rpt. Smithsn. Inst., 1913, pp. 439-458*).—This is a discussion of the subject in its many phases.

Birds that destroy grapes, A. W. BUTLER (*Proc. Ind. Acad. Sci., 1912, pp. 53-55*).—This brief report of observations of the birds that attack grapes supplements the information presented in the author's work on the Birds of Indiana.^a

Species which have reared young and hybrids which have been bred in captivity in Great Britain, W. T. PAGE (*Ashbourne, England: The "Avian*

^a Ind. Dept. Geol. and Nat. Resources Ann. Rpt., 22 (1897), pp. 515-1187.

Press," 1914, pp. VII+55, pls. 5, figs. 7).—The introductory chapters of this work discuss breeding hints and observations. Lists of the species of birds which have reared young in captivity in Great Britain (pp. 10-28) and the hybrids which have been bred in captivity in Great Britain (pp. 30-39) follow. The appendixes include lists of species and hybrids which have been bred on the Continent but not in Great Britain, and a list of the species which have been crossed successfully with the domestic canary. An index is included.

Insects: Their life histories and habits, H. BASTIN (*New York: Frederick A. Stokes Co.*, 1913, pp. XII+349, pls. 46).—This is a popular work dealing with the subject under the following chapter headings: The dominant insect; the young insect; the origin of insects; mouth parts, wings, and legs; the classification of insects; the senses of insects; the behavior of insects; protective resemblance; warning colors and mimicry; the problem of defence; carnivorous insects; plant-eating insects; insects and flowers; the enemies of insects; the courtship of insects; the insect as a parent; insect communities; insects in the water; and mankind and the insect.

Injurious insects, R. T. NEAL (*Hampton Leaflets*, 7 (1915), No. 3, pp. 53, figs. 49).—A brief popular account of insects, particularly those injurious to fruits, shade trees, vegetables, field crops, stored grains, and to health.

Report of the Kansas State Entomological Commission for 1913 and 1914 (*Rpt. Kans. State Ent. Com.*, 1913-14, pp. 16).—Brief reports are presented by G. A. Dean and S. J. Hunter on nursery, orchard, and apiary inspection work.

Report of the entomological department of the Rhode Island State Board of Agriculture, 1913, A. E. STENE, C. W. LOVELAND, and A. C. MILLER (*Ann. Rpt. Bd. Agr. R. I.*, 29 (1913), pp. 23-54).—This report includes notes on some of the important insect pests of the year, work with the elm leaf beetle and San José scale, and nursery and orchard inspection. A report on apiary inspection, by A. C. Miller (p. 43), and a report on the gipsy and brown-tail moth work are appended.

Report of the entomologist, W. H. PATTERSON (*Govt. Gold Coast, Rpt. Agr. Dept.*, 1913, pp. 18-27).—This is a report of the work of the year, particularly as relates to the two major pests of cacao, namely, "Sankonnabe" (*Sahlbergella singularis* and *S. theobroma*) and "cocoa mosquito" (*Helopeltis* sp.), the damage caused by which is said to be enormous.

Insect pests of Nigeria, W. A. LAMBORN (*Bul. Agr. Dept. South. Prov. Nigeria*, No. 1 (1914), pp. 8).—This is the first of a series of leaflets dealing with the insect pests of Nigeria and measures for their control.

The agricultural pests of the southern Provinces, Nigeria, W. A. LAMBORN (*Bul. Ent. Research*, 5 (1914), No. 3, pp. 197-214, pls. 9, figs. 4).—This paper, based upon observations made during the year 1913-14, lists the insect pests under the various crops attacked, namely, cotton, cacao, kola, coffee, maize, rubber, peanuts, beans, pigeon pea, oil palms, and sweet potatoes.

Pests of cotton in Fergana, according to observations made in 1913, I. V. VASSILIEW (*Trudy Būro Ent. [St. Petersburg]*, 10 (1914), No. 10, pp. 23, figs. 13; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 5, pp. 311-314).—A report of observations of insect pests made by the author in 1913 in Fergana, the principal cotton-growing district of Russian Turkestan.

Report of the entomologist and vegetable pathologist, H. TRYON (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1913-14, pp. 114-120).—Work with insects for the year ended June 30, 1914, is briefly reported upon.

Among the pests discussed is a fly, *Musca ocellatissima*, which has been given the name "eye fly." It has been found to harbor a larval parasite, apparently a species of *Habronema*, the adult form as well as the final host of

which remains to be discovered. It is thought that this may represent *Onchocerca gibsoni*, the cause of the verminous nodules in cattle, accounts of which by others have been previously noted (E. S. R., 31, p. 182; 32, p. 376).

Insect pests of coconuts (*Agr. News [Barbados], 14 (1915), No. 333, pp. 42, 43*).—A summarized account of coconut insect pests, particularly the black or rhinoceros beetle (*Oryctes rhinoceros*), and the red beetle or Asiatic palm weevil (*Rhynchophorus ferrugineus*).

Insects affecting the lime, F. W. URICH (*Proc. Agr. Soc. Trinidad and Tobago, 15 (1915), No. 1, pp. 16-18*).—Brief notes on the more important enemies of the lime in Trinidad.

In regard to the poisoning of trees by potassic cyanid, F. SANFORD (*Science, n. ser., 41 (1915), No. 1049, pp. 213, 214*).—A supplement to the article previously noted (E. S. R., 32, p. 152).

Homemade lime-sulphur concentrate, E. W. SCOTT (*U. S. Dept. Agr. Bul. 197 (1915), pp. 6*).—This is a report of work conducted at Berryville, Winchester, and Vienna, Va., Hagerstown, Md., and Benton Harbor, Mich., for the purpose of encouraging orchardists in the preparation of concentrates for their own use, or for the use of the neighborhood.

The results of cooking different lots of lime and sulphur in the different localities are reported in tabular form. The best methods of preparing the lime-sulphur concentrate and the relative cost are described.

Concerning some medico-entomological problems, E. MARTINI (*Arch. Schiffs u. Tropen Hyg., 18 (1914), Beihefte 7, pp. 67-76, fig. 1*).—This article deals especially with the habits of mosquitoes.

The effect of *Coccobacillus acridiorum* on *Pachytylus migratorius*, D. BORODIN (*Ent. Věstník [Kief], 2 (1914), No. 1, pp. 54-86, fig. 1*).—During the summer of 1913 the author conducted experiments in the Government of Stavropol in North Caucasus, during the course of which *C. acridiorum* was injected into the abdominal cavity of several Orthoptera, namely, *P. migratorius*, *Edaleus nigrofasciatus*, *Stauronotus maroccanus*, *Arcyptera flavicosta*, and *Tmetis muricatus*.

The results are summarized as follows:

These injections were pathogenic for all these insects and brought about death in 83 hours. The virulence had been increased by passing the infection through many series of *P. migratorius*. The increase of the pathogenic strength of the culture was ascertained, and in the first two series death resulted in 83 hours, while in the following series (up to the fourteenth) the time decreased to six hours. All the insects do not die in the earlier series; some continue to live and may possibly acquire immunity. Death results more or less quickly, depending upon the conditions of the experiment (temperature and amount of culture injected). If the infection is introduced by the mouth, death results very slowly and all the insects do not die. These results show that the bacteriological method of locust destruction should be avoided until the question has been more thoroughly studied. So far the method of destruction by poisoned baits has given by far the best results.

***Nysius senecionis* as an enemy of newly planted vines**, F. PICARD (*Vie Agr. et Rurale, 3 (1914), No. 22, pp. 610, 611; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 9, pp. 556, 557*).—This lygeid, previously nearly unknown, is reported to have injured newly planted vines in Aude, Hérault, and Gard in 1912 and 1913. In one locality some 12 acres of newly planted vines were so thickly infested by this bug that in places the plants and ground appeared black. One-third of the vines are said to have withered and to have been apparently destroyed.

The sugar cane scale (*Chionaspis tegalensis*) and its control, P. VAN DER GOOR (*Arch. Suikerindus. Nederland. Indië*, 22 (1914), No. 43, pp. 1545-1578, pl. 1; *Meded. Proefstat. Java-Suikerindus.*, 4 (1914), No. 30, pp. 655-688, pl. 1).—An account of the biology, natural enemies, and control measures for this pest in Java.

The gipsy moth in the Crimea, I. SHTCHEGOLEV (*Sadovod*, 1914, Jan., pp. 18-30; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 5, pp. 274, 275).—A short report of an outbreak of *Lymantria dispar* which took place in the Crimea in 1913.

The apple-tree tent caterpillar, A. L. QUAINANCE (*U. S. Dept. Agr., Farmers' Bul.* 662 (1915), pp. 10, figs. 7).—A popular account of this important pest including methods of control.

A new cotton-seed moth (*Mometa zemiodes*) from West Africa, J. H. DURRANT (*Bul. Ent. Research*, 5 (1914), No. 3, p. 243).—*M. zemiodes* belonging to the family Gelechiidae, which attacks cotton seeds in Southern Nigeria, is described as representing a new genus and species.

The fight against *Cydia* (*Carpocapsa*) *pomonella* and *C. (Grapholita) funebrana*, N. KOSTAREV (*Plodovodstvo*, No. 1 (1914), pp. 32-38; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 5, pp. 291, 292).—The author reports that the codling moth causes an enormous amount of damage to apples, as high as 60 per cent occurring in the Crimea, while in the Governments of Astrakhan and Ekaterinoslaf and elsewhere it is as high as 90 per cent. The injury by *C. funebrana* is more indirect than direct, since its attack induces the development of rot fungi (*Monilia fructigena* and *M. cinerea*).

Cydia (Grapholita) funebrana, its bionomics and methods of fighting it, K. KOSTROVSKY (*Turkest. Selsk. Khoz.*, 1914, pp. 133-138; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 5, p. 318).—The author states that *C. funebrana* is as serious an enemy of plums in Turkestan as is the codling moth of apple trees.

Experiments on the artificial infestation of *Agrotis segetum* with parasitic Hymenoptera, W. POSPIELOW (*Ztschr. Wiss. Insektenbiol.*, 10 (1914), No. 2, pp. 52-58).—This is a report of experiments with the Wintersaateule (*A. segetum*), conducted by the author in Voronezh. The parasites employed included an ichneumonid (*Amblyteles vadatorius*), a braconid (*Macrocentrus collaris*), and a chalcidid (*Pentarthron semblidis*). Particular success was met with in the parasitism of the eggs by *P. semblidis*.

The Hessian fly, R. L. WEBSTER (*Iowa Sta. Circ.* 22 (1915), pp. 4, figs. 6).—A popular account of this pest with control measures. The most severe outbreak ever experienced in Iowa is said to have occurred in 1914 over a large part of the southern half of the State, particularly the southwestern portion.

The sorghum midge in Tucumán, A. H. ROSENFELD and T. C. BARBER (*Rev. Indus. y Agr. Tucumán*, 5 (1914), No. 2, pp. 85-87).—The cecidomyiid *Contarinia (Diplosis) sorghicola*, an account of which by W. H. Dean, of this Department, has been previously noted (*E. S. R.*, 23, p. 364), is reported as the source of considerable injury in Argentina.

The prophylaxis of malaria with special reference to the military service, C. F. CRAIG (*War Dept. [U. S.], Off. Surg. Gen. Bul.* 6 (1914), pp. 115, pls. 13, figs. 7).—Chapter 2 of this work deals with the malaria mosquitoes (pp. 41-57), chapter 3 with prophylactic measures based upon the destruction of malaria mosquitoes (pp. 58-71), and chapter 4 with prophylactic methods based upon the protection of man from the bites of mosquitoes (pp. 72-79).

Mosquito-borne diseases (*Washington: Health Dept. Canal Zone, 1914, pp. 19*).—A popular account issued by the Health Department for use in the public schools of the Canal Zone.

A clinical, pathological, and experimental study of the lesions produced by the bite of the "black fly" (*Simulium venustum*), J. H. STOKES (*Jour. Cutaneous Diseases, 32 (1914), Nos. 11, pp. 751-769, figs. 5; 12, pp. 830-856, pls. 3; abs. in Jour. Amer. Med. Assoc., 63 (1914), No. 22, p. 1981; 64 (1915), No. 3, p. 274*).—The first part of this paper consists of a brief account of simuliids, a review of the literature, and a description of the lesions with their associated manifestations. The second part comprises studies of the pathology of the lesions in man and experimental studies in the reproduction of the lesions from preserved material, together with observations on the behavior of the toxic agent.

The temperature in a small child which was bitten by *S. venustum* 25 or more times in one afternoon never went above normal, although the lymphadenitis was marked and the child fretful and restless. It is stated that several persons under the author's observation reported having felt "tired and stiff all over" after being severely bitten by the flies early in the season. Nothing comparable to the severe reactions described in the literature has come under the author's observation.

"A distinctive satellite adenopathy of the cervical glands develops in the majority of susceptible persons within 48 hours after being bitten in the typical sites. This adenopathy is marked, discrete, and painful, the glands often exquisitely tender on pressure. It subsides without suppuration. Immunity may be developed to all except the earliest manifestations by repeated exposures. Such an immunity in natives of an infested locality is usually highly developed. There are also apparently seasonal variations in the virulence of the fly and variations in the reaction of the same individual to different bites."

The experiments performed do not identify the nature of the toxic agent. The theories suggested as to its nature are: (1) The toxin may be an alkaloidal base, toxic as such, and neutralized after injection by antibodies produced for the occasion by the body; (2) the injected saliva of the fly may not contain an agent toxic as such, but, like many foreign proteins, becomes toxic only when broken down; (3) lytic agents in the blood serum may play the chief rôle in the liberation of the toxic agent from its nontoxic combination (to this view the author is inclined); or (4) the initial injection of a foreign protein by the fly at the first bite may sensitize the body to that protein.

A list of references to the literature accompanies both parts.

Proposal of new muscoid genera for old species, C. H. T. TOWNSEND (*Proc. Biol. Soc. Wash., 28 (1915), pp. 19-23*).—This paper relates to species of economic importance.

A maggot trap in practical use; an experiment in house-fly control, R. H. HUTCHISON (*U. S. Dept. Agr. Bul. 200 (1915), pp. 15, pls. 3, figs. 4*).—The demonstration during the season of 1913 of a most pronounced migratory habit of house-fly larvæ just before pupation led to experiments with maggot traps, which have shown that as high as 98 or 99 per cent of the larvæ can be captured. The results of an attempt during the season of 1914 to apply the principles of the maggot trap to practical use and to test its efficiency when used to destroy maggots in large masses of manure are here reported.

The maggot trap designed and constructed consisted of a concrete floor with a concrete rim and a pipe in one corner through which water could be drained. A wooden platform supported by legs was constructed over the floor, upon which the stable litter could be thrown. Each day, after the addition of manure

and litter from the stable, the manure on the platform was sprinkled with enough water to moisten it thoroughly without causing any leaching. The results obtained during August and September seemed to show that at least 98 per cent of the larvæ breeding in this manure were destroyed by migrating from the manure and dropping into the water below. Fly counts made before and after the trap was installed indicated an average reduction of from 67 to 76 per cent. That the reduction of flies did not correspond to the percentage of larvæ destroyed is thought to have been due to the presence of several other breeding places well within the range of flight.

"Two difficulties were experienced in the practical working of the trap, viz. the accumulation of a certain amount of straw and debris on the floor under the platform and the breeding of mosquitoes in the water used to drown the fly larvæ. It was also found that low air temperatures hinder migration, and consequently decrease the efficiency of the trap."

Among the merits of the maggot trap mentioned are (1) the comparatively small initial cost and absence of money outlay necessary for its maintenance; (2) the very small amount of additional time or labor required in its operation; (3) the ease with which wagons or manure spreaders can be loaded from the platform; and (4) its adaptability for use at stables where the daily production of manure is large. The conditions which render the trap most effective are the ones which tend to preserve the value of the manure.

A list of nine references to the subject is included.

Observations on blow flies; duration of the prepupal stage and color determination, P. W. WHIRING (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 26 (1914), No. 3, pp. 184-194*).—The studies here reported upon relate to experiments with the various species of blow flies common in New England, especial attention being given to the common green bottle fly (*Lucilia sericata*).

The author finds that the length of the prepupal period of blow flies is determined by environmental rather than hereditary factors. In general, dryness, cold, or agitation due to crowding tend to prevent pupation, while change from dryness to dampness or the reverse induces it. "The prepupal stage may be extended for a long period, four months in one experiment, in warm temperature without injury to the development of adult flies, which emerge from the pupæ in normal condition. Lack of opportunity for the larvæ to bury themselves does not inhibit pupation. Exhaustion of the food supply before the larvæ have attained full size has a tendency to produce undersized but normally formed flies. The causes producing misshapen and imperfectly expanded flies are more obscure, but may be in part due to drying of the pupæ. Delayed pupation in *Lucilia* larvæ is evidenced by a change from white to pink in the fat bodies, but in two genera of larger flies, *Cynomyia* and *Calliphora*, the white color is maintained although considerable shrinkage of the whole body occurs. There is no evidence that overfeeding delays pupation, but much evidence that larvæ will pupate immediately despite the fact that they have had abundant opportunity to overeat."

A tachinid parasite with an intracuticular stage, W. R. THOMPSON (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 2, pp. 83-86, figs. 2*).—This article relates to an undetermined tachinid parasite, probably belonging to the genus *Epalpus*, the first larval stage of which is parasitic on noctuid caterpillars taken by the author on witch-hazel (*Hamamelis virginiana*) brush at Ithaca, N. Y.

Sarcophagidæ of New England: Males of the genera *Ravinia* and *Boettcheria*, R. R. PARKER (*Proc. Boston Soc. Nat. Hist., 35 (1914), No. 1, pp. 77, pls. 8*).—This first paper deals with seven species belonging to three genera,

of which the genus *Boettcheria* and three species belonging to it and three species of *Ravinia* are described as new. The paper is devoted in large part to the external anatomy of the family. The observations of Kelly (E. S. R., 32, p. 60) and others have shown members of this family to be of considerable economic importance as parasites, particularly of grasshoppers.

Appearance of the Colorado potato beetle (*Leptinotarsa decemlineata*) in Germany (*Illus. Landw. Ztg.*, 34 (1914), No. 57, pp. 538, 539, fig. 1; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 9, p. 1248; *Mo. Bul. Com. Hort. Cal.*, 3 (1914), No. 12, p. 534).—The presence of the Colorado potato beetle, which has not been observed to occur in Germany since 1887, has been reported from Hohenwedel, near Stade (Hanover), and its eradication is being undertaken by the Government.

The rose beetle (*Adoretus vestitus*) and the injury it causes in the Samoan Islands, E. FRIEDERICHS (*Ztschr. Wiss. Insektenbiol.*, 10 (1914), No. 2, pp. 41-47, figs. 6; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 9, pp. 1252, 1253).—A descriptive account of this pest which is very abundant in the island of Upolu. In addition to roses it feeds on leaves of the cacao in a characteristic manner, leaving only the outer edges and the ribs untouched. The author recently observed many young cacao plants in a cacao plantation that had been destroyed by this pest. "Even large trees were seriously injured by these insects. Other frequent host plants are *Coffea liberica*, *Hibiscus tiliaceus* ('fau' of the Samoans; almost every plant had its leaves completely devoured), *Terminalia litoralis* ('talie' of the natives), and others. The injury caused by these beetles, with the exception of that to roses (which have no economic importance in Samoa), has not hitherto been very severe; the insect and the injury that it does are, however, on the increase and perhaps before long it may become dangerous."

A trap for turnip fly, H. M. LEFROY (*Jour. Roy. Hort. Soc.*, 40 (1914), No. 2, pp. 269-271, pl. 1).—The author describes the structure of a trap devised for use in combating the blue flea-beetle (*Phyllotreta consobrina*) and the yellow striped flea-beetle (*P. undulata*), important enemies of turnips, swedes, cabbages, and allied cruciferous plants in the seedling stage in Great Britain. The trap consists of two boards (coated with Morlar Hop Wash) set at a slope on a pair of runners, like those of a sledge or toboggan, with a space between. The trap is drawn along the drill so that the plants pass down the space in the middle. In order to disturb the beetles a loop of string hangs from a crowbar and brushes the plants. Thus disturbed the flea-beetles always leap sideways, alight on the sticky boards, and perish.

The cotton and corn wireworm (*Horistonotus uhlerii*), A. F. CONRADI and H. C. EAGERTON (*South Carolina Sta. Bul.* 180 (1914), pp. 16, pls. 4).—A detailed report of studies of *H. uhlerii* conducted largely at Ruffin, Colleton County, S. C., in cooperation with the Bureau of Entomology of the U. S. Department of Agriculture. Preliminary accounts of investigations of this pest by Thomas (E. S. R., 25, p. 560) and by Conradi (E. S. R., 30, p. 545) have been previously noted, as have studies of *Monocrepidius vespertinus* by Eagerton (E. S. R., 33, p. 63), which is associated with and often mistaken for this species.

This species is always found on upland sandy soil and apparently can not live in soil through which the water does not percolate rapidly. Its injury is occasioned through cutting off the feeding roots of plants. Practically all farm crops are attacked, including corn, cotton, cowpeas, oats, rye, peanuts, tobacco, watermelons, etc. The pest has spread from near Snider's Cross Roads, where it was first noticed, until an area of 200 square miles in that vicinity is more or less severely infested. The greatest loss occasioned has been near Snider's

Cross Roads, where the area of heavy infestation covers about 16 square miles. It is thought, however, that when the distribution records are completed the infested territory will be found to include the sandy uplands of the lower and upper pine belts, together with the coastal lands.

Oviposition is thought to continue from June 1 to September 15, the main period being from June 15 to August 10. From 11 to 15 days are required for the incubation of the egg. In a seasonal life history chart the authors indicate that the larvæ may continue feeding up to July of the following year. While the exact number of larval instars has not been determined, it is suggested that there may be 8 or 9. They live almost exclusively within 4 in. of the surface, except when driven to lower depths by either high or low temperatures or lack of moisture in the upper soil and do not appear to range over a very large area, 20 to 30 sq. ft. apparently being the limit. In the laboratory the pupal stage lasted from 9 to 15 days, apparently varying very little with the time of the year.

The numbers of the larvæ appear to be lessened more by cannibalism while in the deep soil than by any other cause. The natural enemies do not appear to be sufficiently numerous to affect their numbers materially. Artificial control measures which include fallowing, crop rotation, etc., have been dealt with more at length by Thomas (E. S. R., 25, p. 560).

Life history notes on the plum curculio in Iowa (Conotrachelus nenuphar), R. L. WEBSTER (*Proc. Iowa Acad. Sci.*, 20 (1913), pp. 313-315).—A record of observations made in Iowa in 1889 (by C. P. Gillette) and in 1910 which relate especially to the dates of appearance of the adults in the spring, emergence of larvæ from apples, and emergence of adults from July 26 on.

Four new injurious weevils from Africa, G. A. K. MARSHALL (*Bul. Ent. Research*, 5 (1914), No. 3, pp. 235-239, figs. 3).—*Eremmus fulleri* n. sp., found attacking the leaves of maize at Pretoria; *Hyperoides fragariae* n. g. and n. sp., which injures strawberries in Cape Province; *Tychius gossypii* n. sp., found on cotton at Cairo, Egypt; and *Cyllophorus rubrosignatus* n. sp., injurious to cultivated figs in Natal, are described.

Results of cooperative experiments in apiculture, M. PETTIT (*Ann. Rpt. Ontario Agr. and Expt. Union*, 35 (1913), pp. 39-51).—This article reports the results of cooperative experiments in 1912 and 1913 relative to the prevention of natural swarming.

Inheritance in the honeybee, W. NEWELL (*Science*, n. ser., 41 (1915), No. 1049, pp. 218, 219).—A brief discussion based upon the author's investigations at the Texas Experiment Station of crosses between the Italian and Carniolan races.

A new species of Habrobracon sp., parasitizing caterpillars of Chloridea obsoleta. Its biology and agricultural importance, S. BOGOLJUBOV (*Turkest. Sclsk. Khoz.*, No. 3 (1914), pp. 281-291, figs. 5; *abs. in Rev. Appl. Ent.*, 2 (1914), Ser. A, No. 7, pp. 423, 424).—Biological notes are presented by the author on a new species shortly to be described by Kokujev that has been found by the author to parasitize *C. obsoleta*.

On the parasitic acari found on the species of rodents frequenting human habitations in Egypt, S. HIRST (*Bul. Ent. Research*, 5 (1914), No. 3, pp. 215-229, figs. 14).—Eight acarids are here dealt with, of which three are species of *Dermanyssus*.

The rat trypanosome, Trypanosoma lewisi, in its relation to the rat flea, Ceratophyllus fasciatus, E. A. MINCHIN and J. D. THOMSON (*Quart. Jour. Micros. Sci. [London]*, n. ser., 60 (1915), No. 240, pp. 463-692, pls. 10, figs. 24).—In the introduction to this paper the authors present notes on *C. fasciatus*, its anatomy (including methods of dissection), parasites, histological structure

of its stomach, and technique. The development of *T. lewisi* in the flea is considered at length and an experimental study of the problems of transmission and development is reported upon. A list of bibliographical references is appended.

FOODS—HUMAN NUTRITION.

Kansas flours—chemical, baking, and storage tests, C. O. SWANSON, J. T. WILLARD, and L. A. FITZ (*Kansas Sta. Bul. 202 (1915), pp. 135, figs. 21*).—In the first part of this bulletin the equipment used and methods followed in baking tests are described in detail.

The second part of the publication gives the results of baking tests and chemical analyses made of 35 samples of commercial flour collected from Kansas mills, together with the results of chemical analyses of 21 wheats representing those from which the flours were made. The flours examined were divided into three grades designated as short patent, long patent, and straight. In the baking tests, which showed all these flours to be of good quality and strength, a comparative study was made of the following factors: Loss in mixing and rising, time for proving, expansion of the dough, rising in the oven, loss in baking and cooling, weight of the loaf, pounds of bread per barrel of flour, volume of the loaf, texture of the crumb, and color of the loaf.

The following quotations from the discussion of the results of the baking tests of commercial flours are of interest:

“The dough from the short patent ripens sooner. This is one of the qualities in the short patents which make these flours more valuable for family baking where the same flour is used for various purposes, such as cakes and pastries aside from bread making. The gluten is of a softer, more pliable nature and lends itself more readily to different conditions. The dough from a short patent is always softer, and has a smoother, more even feel than the dough from a straight flour. Hence it is easier to work and is much preferred by the housewife. . . .

“The final weight of the loaf, and consequently the amount of bread per barrel of flour, is influenced more by the losses in making than by the variation in materials used. . . .

“Large loaf volume is not of itself an indication of a particularly desirable flour. Sometimes . . . a weak flour may produce a larger loaf than a strong flour. The loaf volume must be judged together with absorption, maximum volume of dough, rise in the oven, and texture. If two loaves are equal in these other factors, then the one with a larger loaf volume is the more desirable. . . .

“That the average loaf volume is greater for the long patent flours than for the other two brings out the fact that loaf volume alone does not necessarily indicate a flour of the highest commercial grade. . . .

“If two loaves have the same volume but one has a larger oven spring, the latter indicates a stronger, stiffer gluten, while the gluten of the former would be weaker or more ‘runny.’”

In judging texture of the crumb, “large holes and uneven distribution indicate a weak gluten. Thickness of cell wall or an appearance of coarseness indicates a stiff and inelastic gluten. Such a flour would be good for blending with a weaker flour, but would not be a desirable flour to be used along for household purposes. Weakness of gluten shown by large and uneven distribution of holes is one of the worst faults in a flour. As a rule, the bread from short patent flours differs from the longer patents and straights by the finer cell walls and more delicate structure. . . .

“One difficulty in judging color is to distinguish true color from the color appearance as influenced by texture. The desired color is white with a delicate creamy tint. . . . A yellow tint is much less objectionable than a grayish tint or a chalky white. The yellow is due to the color inherent in the wheat kernel, while a grayish tint shows faulty cleaning of the wheat or imperfect dressing of the flour.”

The third part of the bulletin presents the results of a study of the chemical composition and baking qualities of 19 flours from a four-break mill, and 26 samples from a five-break mill.

In the chemical analyses of the commercial flours and of the samples from the two mill streams, determinations were made of ash, protein, gliadin, gluten, acidity, total and water-soluble phosphorus, and of hygroscopic moisture. It was found that a definite relationship existed between the acidity and phosphorus content, that the variation in the moisture content of the flour was more affected by the water used in tempering than by a variation of the moisture originally present in the wheat, and that the protein content of the flour depended upon that originally present in the grain and on the method of milling.

“That the proteins of a wheat flour strongly influence the baking qualities of the same is undoubtedly true, but the question is more complex than merely ascertaining the ratio between gliadin and the rest of the proteins. . . . The other proteins may have as much to do with the baking qualities as gliadin, and it is not only the proteins present in the sound wheat kernel which determine the baking qualities, but also the protein decomposition products. . . .

“The short patent has the lowest per cent of ash, while the low grade has the highest. The ash content is lowest in those streams which come from the interior of the kernel, while it is highest in those streams which are taken from that portion next the bran. . . .

“The protein content follows almost the same law of variation as the ash. . . .

“There is a gradual increase in acidity in the flour streams in proportion as they contain material next to the bran. . . .

“The percentage of ash furnishes a very good indication in regard to the quality of a flour as far as that is related to the method of milling. . . . the feed contains ten times as high percentage of ash as the flour. Consequently, the presence of fibrous materials in the lower mill streams influences the ash content more than any other factor. The composition of the ash is also important in judging the baking qualities of a flour. . . .

“The patent has a lower percentage of protein than the wheat, while both the clear flours and the low-grade flours have a higher percentage. The break flours have a regular increase in protein percentage corresponding to the break number, the fifth break being the highest in percentage of protein in all these flours, while the bran-duster flour and the fourth break have the next highest percentages. In the middlings there is almost the same regular increase in protein content corresponding with the number of reductions.”

In the fourth part of the publication is considered the effect of storage upon flour as determined by chemical analyses and baking tests. The work, which extended over two seasons with bleached and unbleached flours stored in a steam-heated room, a nonheated room, and in sealed cans, showed that on storage flours may lose 2 per cent of their original weight, the loss being mostly one of hygroscopic water. The chemical composition and baking quality are otherwise very little affected by storage.

[Wheat and flour analysis] (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, pp. 100-107, pls. 2*).—The results are given of chemical analyses and the grading of a number of samples of wheat and wheat flour. The samples

were graded according to a point system based upon the appearance of the grain, its yield in bushels per acre, its weight in pounds per bushel, the appearance and composition of the gluten, and the color, chemical composition, and baking quality of the flour

Bleached flour, F. L. HALEY (*Biochem. Bul.*, 3 (1914), No. 11-12, pp. 440-443).—Analyses showed the presence of nitrites in bleached flour. From the results of experiments with laboratory animals (guinea pigs), to which were administered doses of potassium nitrite, the author concludes that bleached flour is not detrimental to health.

The physico-chemical properties of the alcohol-soluble proteins of wheat and rye, J. GRÓH and G. FRIEDL (*Biochem. Ztschr.*, 66 (1914), No. 1-3, pp. 154-164, fig. 1; *abs. in Zentbl. Physiol.*, 29 (1914), No. 5, p. 225).—Wheat gluten contains only one protein which is soluble in alcohol, namely, gliadin. Rye flour contains a mixture of several proteins, but apparently not any gliadin.

The physical chemistry of bread, LORENZ (*Chem. Ztg.*, 37 (1913), No. 78, p. 783).—From studies of the structure of both fresh and stale bread the author concludes that as the loaf ages the structure of the starch granules is modified and the starch gives up its water content to the protein part of the loaf. He regards the fresh loaf as an unstable form and the modified starch grains as a permanent characteristic of stale bread.

German agricultural breads, E. PAROW (*Ztschr. Spiritusindus.*, 37 (1914), No. 53, pp. 593, 594).—Surveying the German food supply, the author recommends an increase in the amount of sugar in bread making as a means of increasing its nutritive value and at the same time saving the grain supply.

War bread, H. STRUBE (*Deut. Landw. Presse*, 42 (1915), No. 12, pp. 87, 88).—The author discusses the production and use of this product, which is defined as rye bread containing more than 20 per cent of potato flour.

The use of potatoes in bread making, M. P. NEUMANN and A. FORNET (*Ztschr. Gesam. Getreidew.*, 6 (1914), No. 10-11, pp. 193-205).—Commercial methods are described for the preparation of potato flakes, potato flour, and potato starch. From analyses of bread prepared with the addition in varying proportions of potato flour and starch to rye and wheat flour the author concludes that the best bread is prepared by the addition of 5 per cent of potato flour to the rye or wheat flour, though 10 per cent is often used and even 20 per cent may yield a satisfactory product. When more than 10 per cent of the potato flour is used it is difficult to obtain a good bread, as considerable water is absorbed by the starch in making the dough and the resulting loaf is too soggy.

Composition of *Euchlœna mexicana*, J. PIERAERTS (*Bul. Assoc. Chim. Sucr. et Distill.*, 31 (1914), No. 9, pp. 655-660).—A description is given of a grain commonly occurring in Mexico and other tropical countries which is said to have considerable food value. Its approximate chemical composition is given as follows: Protein 24.57 per cent, fat 4.80 per cent, and carbohydrate, 61.38 per cent.

Nutritive value of frozen meat, E. VALENTI (*Gior. R. Soc. Ital. Ig.*, 35 (1913), No. 4, pp. 148-153; *abs. in Zentbl. Biochem. u. Biophys.*, 16 (1914), No. 17-18, p. 656).—Comparative analyses are reported of American and Italian frozen meats. In the case of meat which had remained at a temperature of -10° C. for 40 days, an increase was noted in the percentage of dried residue and nitrogenous substance, while a decrease was noticed in the water content. It is suggested that the results may vary if a gradual thawing of the meat is brought about.

Utilization of pork in provisioning the army, A. C. GIRARD (*Bul. Soc. Nat. Agr. France*, 75 (1915), No. 1, pp. 44-51).—An increase in the use of pork as a substitute for beef is urged, chiefly from the standpoint of economy.

The toxicity of some ducks' eggs, P. CARLES (*Ann. Falsif.*, 7 (1914), No. 70-74, pp. 443, 444).—Three cases of food poisoning were attributed to the presence of bacteria in ducks' eggs. Sterilization by long-continued boiling before eating is urged as a necessary precaution.

The influence of the fat content of milk on the rate of digestion, A. KREIDL and E. LENK (*Biochem. Ztschr.*, 63 (1914), No. 2-3, pp. 151-155, figs. 3; *abs. in Zentbl. Physiol.*, 29 (1914), No. 5, p. 223).—Experimental data are recorded which tend to show that the rate of digestion of milk decreases with the increase of fat content.

The nutritive value of boiled skim milk, KLEIN (*Milchw. Zentbl.*, 43 (1914), No. 14, pp. 381-384; *abs. in Zentbl. Biochem. u. Biophys.*, 17 (1915), No. 16, p. 632).—Animal-feeding experiments, here reported, would indicate that there is no difference between the nutritive values of boiled and unboiled skim milk.

Cow's milk and vegetable milk; difference in gastric digestion with special reference to the problem of cow's milk intolerance, A. FISCHER (*Arch. Verdauungskrank.*, 20 (1914), No. 1, pp. 13-48; *abs. in Ztschr. Kinderheilk.*, Ref., 8 (1914), No. 3, p. 114).—Comparative experiments with laboratory animals (dogs) are reported in which was studied the digestibility of a vegetable milk prepared from almonds and Brazil nuts as compared with that of cow's milk. The vegetable milk caused a smaller and less prolonged secretion of gastric juices than did cow's milk, but was more readily digested owing to its finely divided condition. The following conclusions are drawn:

Vegetable milk is an emulsion similar to cow's milk and contains carbohydrates, protein, and mineral matter in solution or suspension. The particular vegetable milk studied was characterized by a small content of carbohydrate and salts, especially sodium salts, and when coagulated with acid or rennet the vegetable milk protein formed a more finely divided curd than that formed when cow's milk was treated in the same way.

The food value of the vegetable milk depends upon its method of preparation, the one studied having an energy value of 90 to 115 calories per 100 cc.

The reaction of cow's milk modified for infant feeding, W. M. CLARK (*Jour. Med. Research*, 31 (1915), No. 3, pp. 431-453, figs. 2).—The results are reported of a study of the hydrogen ion concentration of both human and cows' milk as compared with the hydrogen ion concentration of modified cow's milk made up in accordance with various formulas. In the opinion of the author, the practice sometimes followed in modifying milk of adding alkalis to neutralize the acid of cow's milk is based upon wrong principles. This is regarded not only as an unnecessary procedure but one involving possible inhibition of gastric proteolysis and lipolysis. It is further stated that the addition of alkalis tends to replace the normal bacteriological fermentation of the intestine with a putrefactive process which may cause digestive disturbance.

The comparative nutrient value of cod liver oil and cod liver oil cordials, J. P. STREET (*Jour. Amer. Med. Assoc.*, 64 (1915), No. 8, pp. 638-643).—The author reports results of a series of feeding experiments undertaken to compare the nutritive values of cod liver oil preparations, some of which were the so-called "oilless" extracts of cod livers. In conclusion he states that cod liver oil exhibited marked superiority as a food over the commercial extracts studied, and also had the power of restoring growth to laboratory animals (rats) which had suffered from nutritive deficiency when fed upon the commercial preparations.

The mineral constituents of honey, KAPPELLER and A. GOTTFRIED (*Ber. Nahrmtl. Untersuch. Amt. Magdeburg, 1913, pp. 15, 16; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 29 (1915), No. 2, p. 98*).—The analytical data presented show that the ash of honey contains from 10 to 58 per cent of phosphoric acid.

Tomato conserves, P. CARLES (*Les Conserves de Tomates. Bordeaux: Feret & Sons, 1914, pp. 22*).—A discussion supported by analytical data on the composition of normal tomato conserves, their common adulterations, and the hygienic facts pertaining to their use as food.

Observations on mango rash, ISABELO CONCEPCIÓN (*Philippine Jour. Sci., Sect. B, 9 (1914), No. 6, pp. 509-513*).—The author reports some clinical observations which apparently confirm the belief that the so-called mango rash is produced by eating the mango fruit.

The organic flavoring compounds, G. COHN (*Die Organischen Geschmacksstoffe. Berlin: Franz Siemenroth, 1914, pp. XI+936*).—This book is an extended treatise on the organic chemistry of the flavoring compounds. The first part of the volume is composed largely of a general classification. A discussion is given of the influence of chemical composition and constitution upon the degree and kind of taste, and the physiology of taste is also considered somewhat at length. Detailed information is given regarding the more important synthetic sweet flavors, such as saccharin, dulcin, and glucin.

[Inspection and analyses of foods, drugs, and stock feeds], W. A. MCRAE ET AL. (*Bien. Rpt. Dept. Agr. Fla., 13 (1913-14), pp. 190, pl. 1*).—A report of the work carried on under the state food laws during the years 1913-14. Various regulations adopted by the board are reprinted, and general analytical data regarding the samples inspected and the text of the pure food and feed laws are given.

[Food inspection], W. B. BARNEY (*Iowa Dairy and Food Com. Bul. 10 (1915), pp. 27+1, figs. 3*).—General information upon this topic is given and the results shown of prosecutions brought under the state pure food law.

Annual report of the food and drug commissioner [of Missouri], F. H. FRICKE (*Ann. Rpt. Food and Drug Comr. Missouri, 1914, pp. 86*).—The work carried on under the state food and drug laws during the year ended December 31, 1914, is reviewed. This included the analysis of 820 samples of miscellaneous food products, of which 299 did not meet the requirements of the existing standards, and the inspection of establishments where food was prepared and sold—restaurants, hotels, dairies, etc.

[Food and drug inspection], W. M. ALLEN (*Bul. N. C. Dept. Agr., 35 (1914), No. 12, pp. 120*).—This report covers work carried on under the state food laws during the year 1914. Data are given regarding 1,323 samples of miscellaneous foods and food products which were examined.

Eleventh annual report of the food commissioner of the North Dakota Agricultural Experiment Station: Food, Drugs, and Sanitation, E. F. LADD ET AL. (*North Dakota Sta. Rpt. 1914, pt. 2, pp. 41*).—The work of the food commissioner and state chemist during a period of approximately 18 months, ended July 1, 1914, is reviewed, including brief discussions of different phases of the work, reprints of notices and warnings, reports from various members of the staff, etc.

Twenty-eighth annual report of the dairy and food division, S. E. STRODE (*Ann. Rpt. Dairy and Food Div. Ohio, 28 (1913), pp. 128, figs. 6*).—The work carried on during the year 1913 is reviewed, general information being given regarding the inspection of dairies and canning factories, the inspection of drugs, and the examination of eggs. Tabulated data are given regarding the

samples inspected, and a summary of the prosecutions brought by the board completes the report.

Ninth biennial report of the state dairy and food commissioner of the State of Utah, W. HANSEN (*Bien. Rpt. Dairy and Food Comr. Utah, 9 (1913-14), pp. 227*).—General information regarding the work carried on under the state food and drug laws during the years 1913 and 1914 is given. The publication also contains the reports of the sealer of weights and measures, the hotel inspector, and the state dairy and food bureau, the last-named containing general data regarding the inspection and sanitation of slaughterhouses and other places where food is prepared and sold. The report of the state chemist presents analyses of 1,539 samples of miscellaneous food products, of which 1,122 met the requirements of existing standards, and 132 samples of water and ice.

Adulteration of food, A. MCGILL (*Rpts. [etc.] Inland Rev. Canada, 1913-14, pt. 3, pp. 519*).—During the year ended March 31, 1914, 3,825 samples of miscellaneous foods and food products were analyzed, most of the results of which have been reported in bulletins issued by the department. In the appendix to the report 27 of these bulletins are reprinted.

Laws relating to hotels, restaurants, etc., and inspection thereof (*Tallahassee, Fla.*, 1913, pp. 8).—The text is given of a statute enacted by the State of Florida providing for the licensing and inspection of hotels and restaurants, the requirements which such places must meet being specified.

[Inspection of canneries], L. G. BINGHAM (*Agr. Com. Ohio, Food Bur. Bul. 2 (1914), pp. 16*).—A list is given of the canneries inspected, together with their rating. The sanitary code adopted by the state agricultural commission for the regulation of canning and packing factories is given.

Anglo-American cooking. Central-American cooking, S. C. Goy (*La Cuisine Anglo-Américaine. La Cuisine de l'Amérique Centrale. (New York: L. Weiss & Co.), 1915, pp. 489*).—This book contains a large number of recipes for the preparation of dishes common to the United States and Central America.

California Mexican-Spanish cookbook, BERTHA HAFFNER-GINGER (*Los Angeles, Cal.: Citizen Print Shop, 1914, pp. 111+12, pls. 20*).—A book of recipes for the preparation of numerous Spanish dishes, which also contains illustrations of native processes of cooking, ovens, kitchens, etc.

Army rations (*Rev. Sci. [Paris], 53 (1915), I, No. 3, p. 43*).—A note upon the composition of the rations furnished the French and British armies.

Army ration during war time, A. GAUTIER (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 5, pp. 159-167*).—Considerable data are presented regarding the present ration supplied to the French Army. This is stated to consist of the following foods: Bread, 750 gm.; fresh meat, 500 gm.; condensed soup, 50 gm.; dried vegetables, 100 gm.; sugar, 31 gm.; lard, 30 gm.; coffee, 24 gm.; and wine, 250 cc. From the results of several typical dietary studies made with peasant laborers in France the author concludes that this ration, supplying 3,190 calories of energy, is insufficient to meet the body requirements during an active campaign. The recommendation is made that the energy value of this ration be increased to 4,077 calories, by the addition of the following food materials: Bread, 150 gm.; potatoes, 350 gm.; sugar, 32 gm.; fat, 30 gm.; and wine, 500 cc.

The French Army ration in time of war, A. GAUTIER (*Rev. Sci. [Paris], 53 (1915), I, No. 5, pp. 65-70*).—This article contains essentially the same material as the above article except that the results of final dietary studies are cited in support of the author's contention.

Historical review of meat prices in Germany during the past 400 years, G. BADERMANN (*Ztschr. Fleisch u. Milchhyg., 25 (1914), No. 6, pp. 84-87*).—A summary and digest of data.

[The cost of living in Australia], G. H. KNIBBS (*Commonwealth Bur. Census and Statis. Aust., Labor and Indus. Branch Rpt. 5 (1914), pp. 16-67, 100-131*).—A summary and digest of data regarding income and cost of living during the years 1913 and 1914. Information is given regarding the wholesale and retail prices of food and clothing and the cost of rent as compared with other years and other countries.

Cost of living in Australia, G. H. KNIBBS (*Commonwealth Bur. Census and Statis. Aust., Labor and Indus. Branch Rpt. 4 (1914), pp. 36*).—A study of the budgets of 392 different families, which includes information regarding family conditions, the relation of income to expenditure, and the distribution of the expenditure.

Feeding the masses, H. KRANOLD (*Massenernährung Agrarpolitik Kolonisation. Munich: George C. Steinicke, 1914, pp. 95*).—A treatise upon some of the economic problems involved in feeding the poorer classes. Statistical data are also included.

Influence of protein consumption on muscular work, G. C. TESTA and G. SORMANI (*Atti. Soc. Lombarda Sci. Med. e Biol., 1 (1912), No. 3, pp. 363-380, figs. 5; abs. in Zentbl. Biochem. u. Biophys., 16 (1914), No. 7-8, p. 253*).—Experimental study, by means of an ergograph, of the work performed by the gastrocnemius muscle of frogs indicated that the work varied within narrow limits but was considerably increased by the consumption of nucleoproteins.

Studies of the origin of cholesterolin, S. DEZANI and F. CATTORETTI (*Arch. Farmacol. Sperc. e Sci. Aff., 19 (1915), No. 1, pp. 1-9*).—Experiments carried out with laboratory animals (rats) indicate that the animal organism possesses the ability to synthesize cholesterolin when this substance is excluded from the diet.

Absorption of fat and lipoids, E. S. LONDON and M. A. WERSILOWA (*St. Petersb. Med. Wehnschr., 37 (1912), No. 22, pp. 325-327; abs. in Zentbl. Biochem. u. Biophys., 14 (1913), No. 15-16, p. 561*).—In experiments performed on dogs with bilocular fistula below the pancreatic duct or with unilocular fistula in the middle of the small intestine, palmitic acid was 22 per cent absorbed before reaching the distal fistula, though only 7 per cent was absorbed when introduced directly into the intestine instead of per os. Stearic acid was more completely absorbed; in the upper half of the intestine stearin soap was more readily absorbed than fatty acid. The feeding of neutral fat or free fatty acid produced no appreciable change in the fatty acid content of the intestinal mucosa. Neither cleavage nor absorption of cholesterol occurred up to the end of the small intestine.

Further observations on the physiological properties of the lipins of the egg yolk, E. V. McCOLLUM and MARGUERITE DAVIS (*Proc. Soc. Expt. Biol. and Med., 11 (1914), No. 3, pp. 101, 102*).—The addition of small amounts of the ether or petroleum ether extract of cooked egg yolk to a diet of casein, dextrin, and inorganic salts brought about a resumption of growth in the case of laboratory animals (rats) which had ceased to grow on the diet of casein, dextrin, and inorganic salts.

Lecithids contained in cod liver oil, H. ISCOVESCO (*Compt. Rend. Soc. Biol. [Paris], 76 (1914), No. 1, pp. 34, 35*).—Experiments with laboratory animals indicated that repeated doses of olive oil and cod liver oil administered hypodermically in the neck muscles were utilized and caused an increase in weight. Cod liver oil seemed to be better tolerated than olive oil. The author attributes the peculiar properties of cod liver oil to the lecithids it contains. All of the phosphorus, as well as most of the nitrogen compounds in the oil, are said to belong to the group of lecithids and lecithalbumins.

The phosphorus content of the animal organism, W. HEUBNER (*Arch. Expt. Path. Pharmacol.*, 78 (1914), No. 1-2, pp. 24-82).—Analytical and feeding experiments are reported in which was studied the phosphorus content of the bodies of laboratory animals (dogs). In young animals of from 2 to 7 lbs. weight the total phosphorus content of the organism showed very little variation and averaged 0.6 per cent of the total body weight. Of the total phosphorus content 0.15 per cent was found in the muscle, 0.2 per cent in the central nervous system, liver, and kidneys, and most of the remainder in the bones. Lack of phosphorus in the diet decreased the percentage of phosphorus in the body only when growth was indifferent. Under this condition the greatest loss occurred in the bones.

The chemical investigation of the phosphotungstate precipitate from rice polishings, J. C. DRUMMOND and C. FUNK (*Biochem. Jour.*, 8 (1914), No. 6, pp. 598-615).—The authors have failed to isolate the curative substance which occurs in rice polishings, but have confirmed the presence of considerable amounts of cholin and nicotinic acid and have detected betain, adenin, guanin, and possibly guanidin.

Experimental polyneuritis in birds as compared with human beri-beri, R. TASAWA (*Ztschr. Expt. Path. u. Ther.*, 17 (1915), No. 1, pp. 27-46).—From this summary and digest of experimental data the author concludes that the etiology and effects of experimental polyneuritis are not identical with those of beri-beri.

Transactions of the National Association for the Study of Pellagra (*Trans. Nat. Assoc. Study Pellagra*, 2 (1912), pp. XXVIII+409, pls. 7).—Among the papers included may be mentioned: The Problem of Pellagra in the United States, by R. Blue; The Prevalence and Geographic Distribution of Pellagra in the United States, by C. H. Lavinder; Pellagra—Some Facts in its Epidemiology, by R. M. Grimm; Can Pellagra Be a Disease Due to Deficiency in Nutrition, by F. M. Sandwith; Contribution to the Alimentary Balance in Pellagra, by J. Nicolaidi and U. Grillo; and Metabolism in Pellagra, by V. C. Myers and M. S. Fine.

The presence of toxic bodies in expired air, G. FARMACIBIDIS (*Policlin.*, *Sez. Med.*, 20 (1913), No. 3, pp. 116-138, pl. 1, fig. 1; *abs. in Zentbl. Biochem. u. Biophys.*, 16 (1914), No. 11-12, p. 417).—The injection of the condensation liquid of expired air into laboratory animals gave no toxicity with guinea pigs, but with mice a tendency toward toxicity was apparent when compared with the negative results obtained by injections of distilled water or physiological salt solution.

An automatic balance for use in metabolism experiments, E. ABDERHALDEN (*Skand. Arch. Physiol.*, 29 (1913), pp. 75-82, figs. 2).—An illustrated description is given of a balance which records and registers photographically the weight of small laboratory animals.

[Report of the] nutrition laboratory, F. G. BENEDICT (*Carnegie Inst. Washington Year Book*, 13 (1914), pp. 285-297).—A brief summary and review of the investigations being carried on. Notes regarding changes and improvement in equipment, together with a brief review of the publications issued during the year 1914, complete the report.

ANIMAL PRODUCTION.

Annual review of investigations in general biology, compiled by Y. DELAGE (*Ann. Biol. [Paris]*, 14 (1909), pp. XXXIV+545; 15 (1910), pp. XIX+578; 18 (1913), pp. XX+603).—A bibliography of literature published in 1909, 1910,

and 1913 on the cell, reproduction, heredity, variation, the origin of species, and related topics, with abstracts of the more important publications, and continuing similar work (E. S. R., 26, p. 470).

Handbook of comparative physiology, edited by H. WINTERSTEIN (*Handbuch der Vergleichenden Physiologie*. Jena: Gustav Fischer, 1911-1914, vol. 3, 1. half, pp. 2041+XIII, pls. 2, figs. 567; 1910, 1912-1914, vol. 3, 2. half, pp. 1060+XII, pl. 1, figs. 456).—The first half of this very extensive and complete review of work on comparative physiology includes chapters on Physiology of Motion, by R. du Bois-Reymond (pp. 1-248); The Production of Sound and Noise, by O. Weiss (pp. 249-318); Physiology of Supportive and Skeletal Substances, by W. Biedermann (pp. 319-1188); The Color Variation and Chromatic Skin Function of Animals, by R. F. Fuchs (pp. 1189-1656); and Color and Design of Insects, by W. Biedermann (pp. 1657-1994). The second half contains chapters on The Production of Heat, by R. Tigerstedt (pp. 1-104); The Production of Electricity, by S. Garten (pp. 105-224); The Production of Light, by E. Mangold (pp. 225-392); Physiology of Formation, by H. Przibram (pp. 393-456); and Physiology of Reproduction, by E. Godlewski (pp. 457-1022).

Review of experimental breeding investigations in zoology since 1900, A. LANG (*Die experimentelle Vererbungslehre in der Zoologie seit 1900*. Jena: Gustav Fischer, 1914, pp. VII+892, pls. 4, figs. 244).—This comprises a large number of papers reviewing investigations on the theory of inheritance and discussing the biometrical phases of variation and correlation. The latter portion of the volume reviews crossbreeding experiments with animals of the rodentia, carnivora, and unguolata families. Under the latter heading are included the equidae, ruminants, and swine. The topics treated include the inheritance of coat coloring, points of conformation, horns, breed characteristics, milking capacity, and similar items. The papers have been previously reported from other sources.

German zootechny (*Jour. Heredity*, 6 (1915), No. 3, pp. 109-116).—This article is a review of a book by G. Wilsdorf on animal breeding (E. S. R., 27, p. 469), in which he shows the important part the science of genetics has played in the development of the live stock industry of Germany.

Sex determination and sex control in guinea pigs, G. PAPANICOLAOU (*Science*, n. ser., 41 (1915), No. 1054, pp. 401-404).—The author concludes from his observations that "the sex of a guinea pig is determined sometimes by two and sometimes by three factors, depending upon whether the mother has previously borne young. The first factor is the sex tendency of the father. If the father has a male sex tendency, his sons will have a female tendency and his daughters a male tendency. If, on the contrary, the father possesses a female tendency, his sons will have male tendencies and his daughters female tendencies.

"The second factor is the sex tendency of the mother. A mother with a male tendency gives her daughters a female and her sons a male tendency. The mother with a female tendency gives her daughters a male and her sons a female tendency. The third factor is confined to the female and is a change of sex tendency from litter to litter. This change in tendency manifests itself in the following way: If the first litter contains only males, the mother acquires a female tendency for the next litter and vice versa. This new tendency varies in strength, depending upon the number of young of one sex contained in a litter. The greater the number of males in a litter, the stronger the female tendency will be for the next litter. This tendency is still more emphasized if the mother is successively mated with males of a definite tendency, and therefore forced to produce more and more young of one sex.

"In the sons the tendency received from the father is stronger than that coming from the mother, while in the daughters the opposite is true. When one examines the descendants of animals whose fathers had a male tendency and mothers a female tendency, a higher difference in the relative number of males and females is found than from those cases in which the fathers alone had a male tendency. . . .

"Should one select males whose fathers had a female tendency and whose mothers had a male tendency and mate these with females whose fathers had a male tendency and whose mothers had a female tendency, a higher difference in the relative number of males and females will be found in their descendants than in any other possible case."

This regulation in the inheritance of the sex tendency affords an explanation of the manner in which the equilibrium is maintained between the number of male and female offspring of a given species.

A new era in the science of nutrition, R. L. KAHN (*Sci. Amer. Sup.*, 79 (1915), No. 2046. pp. 182, 183).—A review of the work of Osborne and Mendel on problems of animal nutrition.

A chemical study of two drought-resisting forage plants, S. LOMANITZ (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 3, p. 220).—Analyses of the two drought-resisting plants *Chloris virgata* and *Phalaris nodosa*, which have recently been introduced into Mexico, are given as follows: Moisture 8.3 and 9.15, protein 6.87 and 10.54, fat 1.64 and 2.66, nitrogen-free extract 43.38 and 39.06, fiber 28.42 and 25.82, and ash 11.39 and 12.77 per cent, respectively. It is said that both plants are readily eaten by cattle without harmful effect upon the milk.

Feeding sugar-beet tops, F. REDLICH (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 43 (1914), No. 3, pp. 375-404, figs. 6; *abs. in Chem. Zentbl.*, 1914, II, No. 5, pp. 430, 431).—The average analysis of fresh sugar-beet tops (from September to November) is given as water 85.47, protein 1.69, fat 0.28, nitrogen-free extract 7.81, fiber 1.53, ash 1.65, and sand 1.57 per cent. It is deemed a desirable feed for ruminants, more especially milch cows. The beet tops were found to contain from 0.11 to 0.42 per cent of oxalic acid, which is said to have the effect of increasing the milk-fat yield without any unfavorable influence on the milk yield. There was a decline in the lime content of the milk, necessitating the feeding of phosphoric lime in quantities of from 40 to 60 gm. per day. A number of cows fed 43 days on the fresh material made an average daily gain per head of 0.4 kg. in weight.

A drying apparatus is described.

Fish meal as a feedstuff (*Jour. Bd. Agr. [London]*, 21 (1914), No. 8, pp. 689-692).—English experiments carried out with pigs at the Seale Hayne College with fish meal are reported and seem to show that the addition of from 14 to 29 per cent of the meal to other feeds will lead to a marked increase in the weight of the pigs so fed, as compared with those fed on a diet containing no fish meal.

It is suggested that the following quantities might be given daily to the different kinds of stock: Cattle, 2 lbs. per 1,000 lbs. live weight; pigs, $\frac{1}{4}$ to $\frac{1}{2}$ lb., according to weight; sheep, $\frac{1}{10}$ to $\frac{1}{8}$ lb. per 100 lbs. live weight; poultry, adult fowls should receive not more than 10 per cent and chickens not more than 5 per cent of their whole diet in this form. Fish meal with low percentages of oil and salt should be selected and the birds should be gradually accustomed to the feed. The above quantities should in no case be given at once but the fish meal should be introduced into the ration gradually. It is important that decomposition should not have set in.

Feeding experiments with lupine and horse chestnut flakes, E. REISCH, F. EWALD, F. LILIENTHAL, and HANSEN (*Illus. Landw. Ztg.*, 34 (1914), Nos. 42, pp. 391, 392; 43, pp. 399, 400; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 8, pp. 1047-1049).—The composition of lupine flakes and horse chestnut flakes is given as dry matter 82 and 85, protein 25.7 and 6.7, fat 4 and 3.9, nitrogen-free extract 36.3 and 67.8, fiber 9.1 and 3.5, and ash 7.2 and 3.2 per cent, respectively.

Two lots of 12 yearling lambs each were fed a basal ration of meadow hay, mangels, and barley meal, lot 1 receiving in addition 0.4 lb. of bean meal and peanut meal, and lot 2 1.1 lbs. lupine flakes per 100 lbs. live weight. Lot 1 made an average total gain in 73 days of 28.82 lbs. per head and lot 2 of 28.38 lbs., both dressing 47.9 per cent.

Two lots of 12 lambs were fed a basal ration of meadow hay, dried-beet slices, and soy-bean meal, lot 1 receiving in addition 1.1 lbs. wheat bran and 0.66 lb. of corn, and lot 2 2.64 lbs. chestnut flakes per 100 lbs. live weight. Lot 1 made an average total gain during the 73 days of 24.42 lbs. per head and lot 2 of 15.84 lbs., the one dressing 48.8 per cent and the other 45.6. On the whole the chestnut flakes proved unsatisfactory.

Four cows were fed a basal ration of hay, dried-beet slices, and soy-bean meal, and during three periods from 0.8 to 3 lbs. of corn meal and 2 lbs. wheat bran per 1,000 lbs. live weight, in comparison with 2 lbs. chestnut flakes fed during one period and 4 lbs. during another. The chestnut flakes appeared to have no influence on the milk yield. When more than 2 lbs. of the flakes were fed per cow per day the cows suffered from scours. The cows refused lupine flakes because of their bitter taste.

Food for animals and process for the manufacture of the same (*English Patent 24,912, Nov. 1, 1913; abs. in Jour. Soc. Chem. Indus.*, 33 (1914), No. 23, p. 1168).—"Amylaceous material, such as middlings or maize residue, is treated with 2 per cent of its weight of sulphur dioxide in the form of an aqueous solution, and heated for 15 minutes under a pressure of four atmospheres. The steam and acid are then blown off, any remaining acid is neutralized by the addition of calcium carbonate or sodium carbonate, and the product is dried and ground."

Feeding stuffs, LOGES (*Jahresber. Landw. Königr. Sachs.*, 1913, pp. 114-124).—Protein and fat analyses are given of the following feeding stuffs: Rice meal, millet bran, brewers' grains, linseed meal, rape-seed meal, peanut meal, palm-kernel cake, sunflower-seed cake, sesame cake, hemp-seed meal, and fish meal.

[State feeding-stuff laws of the] **American Feed Manufacturers' Association**, compiled by L. F. BROWN (*Milwaukee: Author, 1914, pp. 86*).—This is a brief of the state laws relating to the sale of feeding stuffs.

Feeding of cattle, S. B. LIMA (*Bol. Dir. Geral Agr. [Portugal]*, 11 (1913), No. 4, pp. 244).—This is a compilation of reprints of articles on methods of feeding cattle, the nutritive value of various feeds, and methods of calculating rations.

Wintering store cattle (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 15 (1914), No. 1, pp. 28-33).—Four seasons' experiments are reported in which 3 lots of from 8 to 10 each of 21-month-old crossbred bullocks and heifers were fed five months, beginning December 1, as follows: Lot 1, housed all winter and fed roots, cake, and straw; lot 2, outwintered in the pasture and fed hay and cake; lot 3, outwintered in the pasture and fed hay only. The cake consisted of soy bean and cotton cake. The average gains per head made for the period were 134, 72, and 43 lbs., respectively; the cost per head \$21.22, \$14.96, and \$10.07, respectively.

At the close of the winter feeding the cattle were grazed during the summer for three months under similar conditions, with a resulting average gain per head of 84, 163, and 177 lbs., respectively.

The weight of calves, C. D. STEWART (*Ann. Sci. Bul. Roy. Agr. Col. Cirencester, No. 4-5 (1912-13), pp. 72, 73*).—From careful records taken of 19 Shorthorn cows it was found that the average gestation period of cows bearing bull calves was 288.91 days; of cows bearing heifer calves, 283.75 days. The longest period in the former was 297 days and the shortest period 280 days; in the latter 293 and 274. The average weight of the bull calves was 89.45 lbs.; that of the heifer calves, 82.5 lbs. It was found that the longer the period the heavier the calf in each case. It was noted that the heavier calves are produced from cows in their prime; that is, ranging from 5 to 7 years of age; after this age the calves appeared to become smaller at birth. It is thought safe to take an average of 285 days as the period of gestation and 84 lbs. as the average weight of a Shorthorn calf at birth.

Rye and blue grass pastures, with and without grain, for ewes suckling lambs, H. HACKEDORN (*Missouri Sta. Circ. 73 (1915), pp. 33-40, figs. 2*).—This circular supplements material previously reported (*E. S. R., 32, p. 669*).

Four lots of 8 mature western ewes, each with their 7 to 10, 20 to 22-day-old suckling lambs, were fed 56 days as follows: Lot 1, rye pasture and grain; lot 2, rye pasture; lot 3, blue-grass pasture and grain; and lot 4, blue-grass pasture, the grain mixture consisting of equal parts of cracked corn, oats, and bran. The ewes lost 1.96, 10.19, 2.26, and 11.64 lbs. per head, respectively. Although the ewes in lots 2 and 4 lost heavily, they were thrifty and in healthy condition. The average daily gains of the lambs were 0.468, 0.449, 0.597, and 0.45 lb. per head. The grain consumed by the lambs per 100 lbs. gain was 42.55, 39.33, 41.57, and 49.33 lbs. for the respective lots. The average total grain consumed per ewe in lots 2 and 4 was 99.78 and 110.93 lbs., respectively.

Studies on the variations in the results of factory, microscopic, and breeders' methods of wool sorting, P. KERESZTURI (*Kisérlet. Közlem., 17 (1914), No. 5, pp. 835-866*).—This is a discussion of the advantages of the microscopic method of wool grading, suggesting that it be adopted by manufacturers and breeders, thus obviating the variations in the results obtained by their methods.

Goats and their ancestors, L. BOUTAN (*Bul. Soc. Etude et Vulg. Zool. Agr., 13 (1914), Nos. 10, pp. 168-171; 11, pp. 173-177; 12, pp. 196-201*).—A general discussion of the origin and development of the various breeds of goats in Europe, Asia, and Africa, more especially the Angora, and the importation of this breed to America.

Swine-feeding experiments with chick-peas, O. SCHMIDT (*Fühling's Landw. Ztg., 63 (1914), No. 23, pp. 714-725*).—Chick-peas (*Cicer arietinum*) were fed to pigs and found to compare favorably with barley meal as a feed, the pigs making somewhat greater gains at a slightly lower cost.

Influence of meat and bone meal feeding on the chemical composition of the bony framework, J. K. GJALDBÆK (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsög [Copenhagen], 83 (1913), pp. 26; abs. in Zentbl. Agr. Chem., 43 (1914), No. 10-11, pp. 630-632*).—Three 2-month-old pigs were fed three months, No. 1 receiving an ordinary feed of corn, barley, and skim milk, No. 2 receiving in addition 100 gm. per day of bone meal, and No. 3 from 100 to 400 gm. of bone meal. The control pig increased in weight from 8.1 kg. to 30.9 kg., No. 2 from 9 kg. to 28.3 kg., and No. 3 from 10.3 kg. to 20.5 kg. The head of the femur bone was analyzed and the ash, CaO, and P₂O₅ content found to be greatest in pigs 2 and 3, from which it is concluded that the feeding of

bone meal has a material influence on the development of the bony framework of pigs.

The swine industry in New York State (*N. Y. Dept. Agr. Bul. 64* (1914), pp. 200, figs. 56).—This includes a number of general articles by various authors on the feeding, care, and management of swine.

Prairie farmer's hog book, C. V. GREGORY (*Chicago: Prairie Farmer, 1914*, pp. 126, figs. 65).—This booklet gives complete and practical information on the breeding, feeding, care, and management of hogs for profit.

Horse breeding in relation to national requirements, A. PEASE (*Jour. Farmers' Club [London], 1915, Feb., pp. 21-42*).—This is a discussion of the requirements of horses for the English army service and of methods of increasing the supply of available horses.

Horses, S. B. LIMA (*Bol. Dir. Geral Agr. [Portugal], 11* (1913), No. 10, pp. 468, fig. 1).—This is a collection of reprints of articles treating of the various breeds of horses in Portugal, their development and improvement, and methods of breeding in vogue, more especially with regard to racing and remount stock.

The retention of the amino acids in the metabolism of the fowl, K. SZALAGYI and A. KRIVUSCHA (*Biochem. Ztschr., 66* (1914), No. 1-3, pp. 139-148).—The feeding to ducks of 2 gm. per day of asparagin in addition to corn

slightly lowered the amino acid quotient $\left(\frac{\text{amino acid nitrogen}}{\text{total nitrogen}}\right)$ of the urine as compared with the amino acid quotient of the urine of ducks fed corn alone. On feeding 2 gm. of glycocoll the quotient was somewhat increased, while on feeding molasses high in amino acid content to a hen the quotient was slightly decreased.

On the asparagin feed no amino acid nitrogen was found unresorbed in the feces of the two ducks, while on the glycocoll feed 4.84 and 3.76 per cent remained unresorbed. On the molasses feed 9.03 per cent remained unresorbed in the feces of the hen. The amino acid nitrogen found in the urine of the ducks fed asparagin was 3.77 and 2.83 per cent, respectively; 6.5 and 4.75 per cent, respectively, in the urine of the ducks on glycocoll; and 6.9 per cent in the urine of the hen on molasses feed.

The fact that the values calculated from the relation of the amino acid nitrogen to the nonprotein nitrogen agree gives additional proof that the amino acid resorbed by the organism is not retained, since the oxidation products are found again in the urine quantitatively.

Correlation between egg-laying activity and yellow pigment in the domestic fowl, A. F. BLAKESLEE and D. E. WARNER (*Science, n. ser., 41* (1915), No. 1055, pp. 432-434).—The results tabulated in this paper indicate that a close correlation exists between the yellow pigmentation in a hen and her previous egg-laying activity, and that in Leghorns the color of the ear lobes is perhaps a better criterion of laying activity than either legs or beak and is more readily recorded. It is believed that laying removes yellow pigment with the yokes more rapidly than it can be replaced by the normal metabolism, and in consequence the ear lobes, the beak, and the legs become pale by this subtraction of pigment.

Fancy points vs. utility, A. F. BLAKESLEE (*Jour. Heredity, 6* (1915), No. 4, pp. 175-181, figs. 2).—The author points out the necessity for a revision of standards for judging poultry, showing that very little attempt is made to use characters in the score card indicative of yield, and that in some cases standards are used that are directly opposed to the natural development of the bird. As an example, barring in Plymouth Rocks is cited. It is shown that whereas the males are naturally lighter than the females, poultrymen, in order to win

prizes for exhibition pens, have resorted to so-called double mating, breeding males from dark strains and females from light strains, since judges give preference to pens in which the males and females are matched in shading.

It is further shown that whereas yellow pigment in the beak and the legs of Leghorn and Wyandotte pullets disappears when they begin to lay and returns again when they cease laying (see abstract above), the Standard of Perfection demands yellow in the beak and legs, thus penalizing production. It is suggested that the show-room standards be changed and greater account taken of yield; that judges disqualify for characters indicating low yield; that efforts be made to discover to what extent visible characters are correlated with high production; and that points be allowed commensurate with the degree of this correlation.

Method of selecting the high-producing hens, O. B. KENT (*Cornell Countryman*, 12 (1915), No. 6, pp. 481-484, fig. 1).—The author states that the characters to be used in a study of egg production are time of molting, color of shank, texture of comb, and color of ear lobes. Late molting is the accompaniment of late laying, but late molting does not appear to affect the earliness of spring laying; those hens that molted late molted much more rapidly than those that molted early and hence lost less time. It has been found at the New York Cornell Experiment Station that all of the high producers and some of the low vitality low producers have pale shanks, but that any bird with yellow shanks after a year of laying, whether it be the first, second, or third year of egg production, has been a poor producer for that year. If a bird starts with pale shanks, the shanks will not grow darker, and nothing can be told of the egg production from the shanks alone.

It was further found that those birds which had soft pliable combs in the fall were in general better producers than those with hard or dried-up combs. It was found that there was a very close correlation between a combination of the three factors (time of molting, color of shank, and texture of comb) and egg production.

Studies at the Connecticut Storrs Station (see above) tend to show that those birds that normally have a considerable amount of yellow pigment in their ear lobes before they begin to lay will lay this yellow color out. By means of the ear lobes it is a comparatively easy matter to go through a flock of utility White Leghorn pullets eight months after they are hatched and pick out those that have not laid. The ear-lobe test simply indicates whether the bird is laying or not and does not necessarily indicate that a bird will or will not lay heavily throughout the year.

California poultry practice, SUSAN SWAYSGOOD (*San Francisco: Pacific Rural Press*, 1915, pp. 157, pls. 8, figs. 5).—A general treatise on poultry management.

A poultry survey of Jackson County, F. S. JACOBY (*West Virginia Sta. Bul.* 148 (1914), pp. 3-38, pl. 1, figs. 13).—This is a general résumé of the poultry industry in Jackson County, W. Va., said to be the greatest poultry-producing county in that State. Methods of breeding, feeding, marketing, and general management are described.

Profitable squab breeding, C. DARE (*Des Moines: Author*, 1914, pp. 70, pls. 4, figs. 18).—This booklet contains general information on squab breeding and management.

Breeding for horns, F. N. MEYER (*Jour. Heredity*, 6 (1915), No. 2, p. 96).—This is an account of an industry in Siberia in which stags are bred for their antlers. The antlers are sawed off, boiled in salt water several times, and allowed to dry, in which state they are sold. The average price paid for the antlers is between \$4 and \$6 per pound.

Rabbit culture and standard, W. F. ROTH and C. T. CORNMAN (*Sellersville, Pa.: Poultry Item Press, 1914, pp. 95, pls. 12, figs. 6*).—This booklet deals with the various breeds of rabbits and their feed, care, and management.

DAIRY FARMING—DAIRYING.

Cattle-feeding experiments in Denmark, H. E. ANNETT (*Agr. Jour. India, 10 (1915), No. 1, pp. 63-75*).—This reviews the general plan of conducting cattle-feeding experiments in Denmark. The experiments are largely co-operative and carried on with considerable care. Feeding trials were begun in 1887 and have been continued to the present time, more than 4,000 cows having been utilized.

The general results of the trials have shown that wheat, corn, and bran give much the same results in milk production, while oil meal is slightly better. One lb. of wheat, corn, or bran has been found to be equivalent to 0.75 lb. sunflower cake, 0.67 lb. cottonseed cake, 1.2 lbs. molasses, 2.5 lbs. hay, 5 lbs. straw, or 10 lbs. mangel wurzels. The experiments have indicated that changes of feed have practically no effect on the chemical composition of either the fat or the milk. Variations in the composition of the milk are caused, to a much greater extent, by the individuality of the animal.

Experiments have also been conducted to determine to what extent mangel wurzels can take the place of concentrated feed in the ration. The results indicate that the protein requirements, as determined by the Wolff-Lehmann, Kellner, and other tables, are too high, and that it is possible to substitute during the winter less expensive feeds, such as mangels, for expensive feeds such as cottonseed cake, without decreasing the milk yield or endangering the health of the cattle.

Feeding experiments in Denmark with dairy cattle, W. HELMS (*Agr. Gaz. N. S. Wales, 26 (1915), No. 1, pp. 41-47, fig. 1*).—The author gives data collected by him during a visit to Denmark. Two lots of six cows each were put out on grass and tethered within large measured circles, and at the end of the day the grass left within the circle was cut and weighed. This method of investigation occupied 14 days.

It was found that the quantity of grass consumed by cows was about 155 lbs. per head per day. It varied somewhat, not only as between cows but also in the individual cow from day to day. This variation was not entirely dependent on weather conditions, such as wet, cold, or very warm weather, when the consumption was smaller, but also independently of such conditions. The cows consumed about the same quantity whether they were dry or in milk or whether giving a smaller or greater milk yield. A reduction in the milk yield took place in time, even when the grass was young and fresh.

From these and later trials it is concluded that "feeding with, and on, grass alone, quite apart from the loss sustained by letting the cows themselves decide how much grass to consume, can not give us the most profitable results with dairy cattle, and even if other fodder be added to the grass feed a loss of nourishing organic matter can hardly be avoided.

"On account of the varying quality of the grass, especially as it gets older and its digestibility alters, it is difficult to recommend any certain fodder composition when grass also is given. The feeding in summer time must be even and based on similar systematic principles to the winter feeding, viz, in proportion to the condition and milk production of the various cows in the various periods between 'in calf' and 'calving.' On no account must the change from paddock feed to stable feed, or vice versa, be too sudden."

Some results from the fattening of dairy cows, C. HUTCHINSON (*Jour. Southeast. Agr. Col. Wyc, No. 22 (1913), pp. 161-169*).—In disposing of cows to the butcher it is said that the milk yield of a barren cow should not be allowed to reach an unprofitable level before a fattening ration is allowed. The introduction of such a ration will arrest the normal decline in milk yield. However, it is not thought advisable to allow the cow to dry off completely before sale as beef, but to sell the fat cows direct from the milking herd.

The development of the dairy industry in Hungary, I. KOERFER (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intcl. and Plant Diseases, 5 (1914), No. 12, pp. 1542-1546*).—A statistical review of the development of the dairy industry in Hungary.

The hygienic importance of acid-rennet bacteria in the udder of cows, C. GORINI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 37 (1914), No. 17, pp. 707-711*).—This is an account of acid-rennet-producing bacteria, called *Bacillus minimus mamma*, found in the lactiferous ducts of the udder, and causing the premature coagulation of milk even before it is drawn from the udder and before external contamination.

A zymoscopic or fermentation test appears to be the most practicable method of detecting the presence of the organism. It is said that to prevent the abnormal development of the acid-rennet microflora in the udder it is advisable to milk the cow dry so as to empty completely the lactiferous ducts. In zymoscopic testing of milk the type of coagulum produced by the bacteria may be used as a guide by both cheese maker and veterinarian for indicating faulty milking and abnormal conditions of the udder.

A reinvestigation on the nature of the cellular elements present in milk, R. T. HEWLETT and C. REAVIS (*Lancet [London], 1915, I, No. 17, pp. 855-857*).—This paper deals with methods of preparing, fixing, and staining films preparatory to determining the nature of the cellular elements in milk.

The yellow color in cream and butter, L. S. PALMER (*Missouri Sta. Circ. 74 (1915), pp. 41-46*).—A popular discussion, based on the material previously reported (*E. S. R., 31, p. 273*).

Butter prices, from producer to consumer, N. H. CLARK (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 164 (1914), pp. 59*).—A compilation of statistical data showing the prices paid to the farmer for milk fat as contained in milk and cream, and the prices received for butter by the creameries, wholesale dealers, and retail dealers in the years 1904, 1910, and 1911, for the months of June and December, these being selected as representing the season of high production and low prices and the season of low production and high prices, respectively. Among the topics discussed are seasonal variation in production and the effect of cold storage, movement of wholesale prices in different markets, and butter prices and margins.

Studies on the manufacture of cheese, 1913, 1914, C. GORINI (*Bol. Min. Agr., Indus. e Com. [Rome], Ser. C, 12 (1913), No. 8-12, pp. 80-86; ditto, Ser. B, 13 (1914), II, No. 3, pp. 36-48*).—This treats of the methods of manufacturing the various types of Italian and Swiss cheese, and on the bacteriological phases of cheese making.

The manufacture of cheese from "heated" milk, II, M. BENSON (*Jour. Bd. Agr. [London], 21 (1915), No. 10, pp. 878-889*).—This is a continuation of work previously noted (*E. S. R., 29, p. 674*).

It was found that to obtain a typical Cheddar cheese from pasteurized milk the pasteurizing temperature should not be higher than 190° F. when the milk is heated very rapidly, or 170° when the period of heating is from 15 to 30 minutes. A blue-veined cheese of good quality was obtained when the milk was heated for about 15 minutes to 190 to 200°. This is thought to be due either to

the fact that the loss of elasticity of the curd at the higher temperatures produced a less dense cheese with more widely distributed air spaces, and consequently greater growth of blue mold, or that inhibitory organisms were destroyed in the milk, thus permitting the freer growth of the mold. Cheeses prepared from heated milk contained water 33.61 to 36.22 per cent, fat 32.36 to 34.53, insoluble nitrogen (probably unaltered casein) 2.49 to 2.91; and determinations of acidity, expressed as normal sodium hydroxid per 100 gm. of cheese, 13.2 to 20 cc. The heating resulted in a higher percentage of water in the ripened product. The fat is consequently a slightly lower percentage, and the higher acidity in the heated cheese may be due to the fact that more starter was added in making the cheese.

In the case of very rapid heating, the number of organisms in the milk was not effectively reduced below 170°, but at this point the number was reduced to one-fiftieth of the total, at 180° to one eighty-fifth, and at 200° practically all the organisms were destroyed. There was a much greater reduction when the milk was maintained at 150° for 15 minutes than when it was heated very rapidly to 170°. Complete sterility was not obtained at any temperature.

It was found that there was a definite increase in the number of organisms in the milk from the vat before any starter had been added and the number in the milk as it came from the cooler, indicating that milk once pasteurized should be handled as little as possible before it is put to the use for which it is intended.

The manufacture of condensed milk, milk powders, casein, etc.—Discussion of methods of analysis, R. T. MOHAN (*Jour. Soc. Chem. Indus.*, 34 (1915), No. 3, pp. 109–113).—This is a discussion of the analysis of these various products and the factors influencing their composition and quality.

It is said that milk of different seasons will stand different temperatures, fortunately the highest in the summer. The fresh milk varies in composition with the seasons, and hence the concentration also has to be varied to bring the product up to standard. In June the solids in the fresh milk average 12.68 per cent, in the condensed milk 25.81; in August 11.75 and 26.01; in November 13.40 and 26.62. It is said that swells, flat sours, and sweet curdling in evaporated milk are due to understerilization. Curdiness (other than sour curd) is due to precipitation of the curd as a hard mass under the action of heat on a product of high solids and acidity. The hard grains sometimes found in the bottom of the cans consist of mineral matter, mostly calcium phosphate, precipitated owing to overconcentration.

VETERINARY MEDICINE.

Collected papers from the Research Laboratory, Parke, Davis, and Company, Detroit, Michigan (*Collected Papers Research Lab. Parke, Davis & Co., Reprints*, 2 (1914), pp. IV+289–590, pl. 1, figs. 100).—These papers, which have been previously published in various scientific journals, include articles on hog cholera by W. E. King, R. H. Wilson, G. L. Hoffmann, and F. W. Baeslack (*E. S. R.*, 28, pp. 381, 482, 587; 29, p. 681; 30, p. 383); on canine distemper and equine influenza by N. S. Ferry (*E. S. R.*, 29, p. 682); and on tetanus by C. T. McClintock and W. H. Hutchings (*E. S. R.*, 29, p. 679). Other papers of interest are: The Employment of Protective Enzymes of the Blood as a Means of Extracorporeal Diagnosis.—I. Serodiagnosis of Pregnancy, by C. P. McCord; Standardization of Disinfectants.—Some Suggested Modifications, by H. C. Hamilton and T. Ohno; and Correcting Water, by H. C. Hamilton.

Castration of domesticated animals, F. S. SCHOENLEBER and R. R. DYKSTRA (*New York: Orange Judd Company, 1915, pp. X+154, figs. 53*).—A small handbook intended for the use of stock owners, students of agriculture, and veter-

inarians. The work is presented in such a manner as to be of interest to those not having a knowledge of anatomy or surgical technique.

Chemical studies upon the genus *Zygadenus*, C. L. ALSBERG (*Abs. in Sciencæ, n. ser., 39 (1914), No. 1017, p. 958*).—Alkaloids similar to those occurring in the "veratrin" group were obtained in crystalline form from *Zygadenus venenosus*, *Z. elegans*, and *Z. coloradensis*. All were very toxic and had similar pharmacodynamical properties. From a member of a closely related genus, *Amianthium muscatoricum*, a similar active principle was obtained in the pure state. Apparently many of the species of Liliacæ contain veratrin.

***Zygadenus*, or death camas**, C. D. MARSH, A. B. CLAWSON, and H. MARSH (*U. S. Dept. Agr. Bul. 125 (1915), pp. 46, pls. 6, figs. 4*).—This monograph includes a detailed report of feeding experiments with sheep, horses, and cattle carried on in 1909 and 1910 at Mount Carbon, Colo., and in 1912, 1913, and 1914 at Greycliff, Mont.

This plant grows abundantly on many of the stock ranges of the West and is one of the most important sources of loss to sheepmen. Apparently all species of the genus *Zygadenus* are poisonous throughout the whole season of their growth, although the tops are somewhat more poisonous at the time of flowering. The toxicity of the bulbs and tops is about the same, but the seeds are much more toxic than other parts of the plant. Cases of poisoning are more likely to occur before the maturity of the plant for at that time other forage is scanty.

Investigations have shown that the toxic dose varies according to conditions of feeding. In drenched animals it is put at about 0.5 lb. for an animal weighing 100 lbs. In fed animals it varied from 1.6 to 5.6 lbs. The poisonous principle is an alkaloid or alkaloids allied to veratrin and cevadin. Sheep, cattle, and horses are poisoned by the plant but the fatalities are almost entirely confined to sheep. The principal symptoms are salivation, nausea, muscular weakness, coma, and sometimes attacks of dyspnoea.

No satisfactory medical remedy has been discovered, notwithstanding the fact that the authors did considerable experimental work with different drugs. As a preventive it is important that the plant be recognized and grazing upon it avoided. When animals become sick they should be kept quiet and under such treatment many will recover.

A list of the literature cited, consisting of 30 titles, is included.

The examination of milk by the practicing veterinarian. Testing the protein and sugar content for the purpose of noting single abnormal milks, GLAGE (*Berlin. Tierärztl. Wchnschr., 30 (1914), Nos. 12, pp. 204-206; 14, pp. 234-236*).—After pointing out the various methods whereby the practical veterinarian may detect abnormal milks, especially those of pathological origin, the author shows that sugar and the amorphous protein constituents have not been considered (or only rarely so). When examining milk in these respects a normal amount of protein and sugar point to the healthfulness of the cow from which the sample under consideration was obtained. The protein test recommended consists of making a mixture of 3 cc. of milk and 3 cc. of a 10 per cent ammonia solution, adding an excess of water, and shaking. A healthy milk will show no coagulation, not even on boiling the mixture.

The sugar test is as follows: Boil a mixture made of three parts of milk and three parts of a 15 per cent potassium hydroxid solution, shake, and allow to stand for 10 minutes. A healthy milk gives a brown coloration while pathological milk will show a yellowish or orange color or at the most a yellowish brown. The test is best conducted on skim milk.

See also a note by FETZER (*E. S. R., 27, p. 878*).

The comparative action of nucleinate of sodium upon the coagulation of blood and milk, M. DOYON and F. SARVONAT (*Compt. Rend. Soc. Biol. [Paris]*,

74 (1913), No. 13, pp. 765, 766; abs. in *Zentbl. Expt. Med.*, 4 (1913), No. 10, p. 454).—Sodium nucleinate hinders the coagulation of the blood, but has no effect upon the coagulation of milk.

On the nature of the opsonic substances of normal sera, H. ZINSSER and E. G. CARY (*Jour. Expt. Med.*, 19 (1914), No. 4, pp. 345-361, pl. 1).—There is still much difference of opinion regarding the nature of antibodies by which phagocytosis is increased in normal and immune sera. Lack of agreement has centered chiefly upon the question of whether the opsonins are separate antibodies, independent of those previously known, or whether opsonic effects can be attributed to the activities of the alexin and sensitizer, acting individually or in cooperation.

In the experiments 24-hour cultures of the *Staphylococcus pyogenes aureus* were used in salt solution emulsions. The experiments do not point to a differentiation of normal opsonin from alexin, but the authors believe that they indicate that the so-called end piece can enter to a slight extent into nonspecific relationship with unsensitized bacteria, "and it is therefore active, whereas it can not enter into a similar relation to unsensitized cells. This conception, however, is tentatively made, since we are studying further the nonspecific absorption of alexin or complement by unsensitized bacteria."

Studies on the propagation of bacteria, spirilla, and spirochetes, E. MEIROWSKY ET AL. (*Studien über die Fortpflanzung von Bakterien, Spirillen und Spirochäten*. Berlin: Julius Springer, 1914, pp. VII+95, pls. 19, fig. 1).—This is a biological and morphological study of the tubercle bacillus (obtained from the sputum), leprosy bacillus, and *Bacillus enteritidis* (Gärtner), *B. paratyphosus* B.; *Spirillum rubrum* and *S. tyrogenum*; and spirochetes (fowl spirillosis, balanitis, stomatitis, lues). Spirochetes are deemed members of the plant kingdom.

A bacteriological study of methods for the disinfection of hides infected with anthrax spores, F. W. TILLEY (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 1, pp. 65-92).—This is a report of experimental work that was undertaken primarily to determine the value of the Seymour-Jones method of disinfecting hides as compared with other methods, especially the Schattenfroh method. The work includes a review of the literature relating to the subject, a list of 16 references being appended.

The Seymour-Jones method, which consists in the use of mercuric chlorid 1:5,000, plus 1 per cent of formic acid, was not found to be efficient, even without neutralization of the disinfectant. A dilution of 1:2,500, plus 1 per cent of formic acid, was found to be efficient where no neutralization was attempted, but the latter strength was not sufficient to prevent fatal infection of guinea pigs by disinfected material when the disinfectant was neutralized by a 1 per cent sodium-sulphid solution three or four days after the completion of the process of disinfection. No infection was caused by the inoculation of material which had been kept for a week or more after disinfection. It appears that this method might be employed when hides are disinfected at foreign ports before shipment to this country.

The Schattenfroh method, which consists in the use of hydrochloric acid and sodium chlorid in the proportions of 2 per cent of the acid and 10 per cent of the salt and with 48 hours' exposure, proved efficient in every instance. While this method can not be regarded as perfect it seems to be far superior to other methods and well worth a trial as a standard method for the disinfection of hides.

From information furnished by F. P. Veitch of the Bureau of Chemistry in regard to the tanning of small pieces of normal hide treated by the Seymour-

Jones and Schattenfroh processes of disinfection it appears that neither exerts any injurious effect upon hides or leather.

Bacteriological tests were also made with formalin and phenol and the pieces of hide treated by these disinfectants examined and tanned in the Leather and Paper Laboratory of the Bureau of Chemistry. So far as could be determined by a limited number of tests $2\frac{1}{2}$ per cent of formalin is efficient bacteriologically, both against anthrax spores and against other organisms, while 5 per cent of phenol is fairly efficient against nonspore-bearing organisms but is practically useless against anthrax spores. Pieces of hide disinfected by formalin in $2\frac{1}{2}$ per cent solution were so seriously affected by the disinfectant that it was almost impossible to tan them, while pieces treated with carbolic acid were uninjured.

During the course of the investigation the author noted considerable variation in the vitality and virulence of anthrax spores from different sources.

The susceptibility of animals to infectious bulbar paralysis. S. VON RÄTZ (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 2, pp. 99-106; *abs. in Amer. Vet. Rev.*, 46 (1915), No. 6, pp. 587-589).—The author finds that wild boars and carnivora (foxes) are susceptible to Aujeszky's disease.

Curative experiments with salvarsan in infectious bulbar paralysis. F. HUTYRA (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 82, pp. 578, 579).—In the first series of experiments conducted use was made of a virus obtained from artificially infected rabbits, pieces of brain the size of a pea being emulsified in 8 cc. of bouillon. Each of four rabbits was subcutaneously injected with 1 cc. of the emulsion, followed at different intervals by the intravenous injection of 0.01 gm. of salvarsan per kilogram of body weight. In a second series of seven rabbits use was made of a virus obtained through emulsifying 0.5 gm. of brain substance in 100 cc. of physiological salt solution. Ten cc. of this emulsion was injected, and the dosage of salvarsan was increased to from 0.04 or 0.08 gm. per kilogram of body weight.

All four of the animals in the first series succumbed to the disease but three of the seven in the second series, two in which the salvarsan was administered at once after the infection and one in which it was administered 24 hours after the infection, recovered. It is suggested that the cure of the last-mentioned rabbit may have been due to a particularly high natural resistance.

Foot-and-mouth disease. J. W. CONNAWAY and D. F. LUCKEY (*Handy and Pract. Farm Libr. [Missouri], Mo. Bul.*, 12 (1914), No. 11, pp. 5-36, figs. 5).—A description of the disease, its ravages in the United States and abroad, with special reference to the most recent epizootic. Diseases which may be mistaken for foot-and-mouth disease are also discussed.

Virus carriers as factors in the spread of foot-and-mouth disease. J. R. MOHLER and A. EICHHOEN (*Amer. Jour. Vet. Med.*, 10 (1915), No. 5, pp. 310-315, 340).—The authors here review the literature relating to virus carriers of foot-and-mouth disease, the number of which appears to be relatively small. It appears that animals which have apparently recovered from the disease must be kept separated from healthy cattle for at least seven months until all danger of their being virus carriers has passed. It still remains to be determined what part of the body harbors the virus.

Hay as a carrier of the virus of foot-and-mouth disease (*Landw. Umschau*, No. 9 (1914); *abs. in München. Tierärztl. Wchnschr.*, 65 (1914), No. 12, p. 279; *Vet. Rec.*, 27 (1915), No. 1385, p. 390).—An outbreak of foot-and-mouth disease on a farm in the district of Aurich is thought to have originated in hay that had been cut and kept in a stack for nearly 2.5 years.

Transmission of foot-and-mouth disease to a dog, MARTIN (*München. Tierärztl. Wchnschr.*, 57 (1913), No. 38, p. 708; *abs. in Vet. Rec.*, 27 (1915), No. 1385, p. 390).—The author records a case of foot-and-mouth disease in a St. Bernard dog that ate pieces of horn from the claws of animals affected with the disease.

Mastitis complicating foot-and-mouth disease as a secondary infection of the udder, RAMELLA (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig.*, 37 (1914), No. 3, pp. 121-123; *abs. in Vet. Rec.*, 27 (1915), No. 1385, pp. 389, 390).—An outbreak of foot-and-mouth disease in the autumn, winter, and spring of 1913-14, although benign in form, is said to have presented the predominant feature of predisposing the patients to secondary infection, particularly mastitis, with which from 10 to 20 per cent, or even more, of the cows became affected.

Through the systematic disinfection of the udder of cows affected with foot-and-mouth disease for a period of about 20 days with a tepid 5 per cent solution of lysoform the cases of mastitis became fewer in number and milder. Since the losses from mastitis are sometimes greater than those caused by foot-and-mouth disease itself, the author considers the disinfection of the udder necessary whenever foot-and-mouth disease appears and the sole means of averting this complication.

Remarks on the serodiagnosis of glanders, W. PFEILER, G. WEBER, and F. SCHÖMMER (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 19, pp. 320-322).—One horse out of seven tested by the conglutination (E. S. R., 28, p. 478), agglutination, and complement-fixation methods failed to react by both the conglutination and complement fixation methods. This animal when tested by the ophthalmic mallein test gave a positive reaction and on slaughter was found to be glandered. This and other reasons led the authors to modify some of the features of the conglutination test with a view to obtaining greater accuracy.

Investigations on the utility of the conglutination method for the serodiagnosis of glanders in horses, O. WALDMANN (*Arch. Wiss. u. Prakt. Tierheilk.*, 40 (1914), No. 4-5, pp. 382-394).—The method was studied on three horses artificially infected with the glanders bacillus. The agglutination and complement fixation tests were carried out at the same time, the procedure prescribed by Pfeiler and Weber for conducting the conglutination tests (E. S. R., 28, p. 478) being adhered to closely.

The conglutination and complement fixation tests showed inhibition on the same day and it reached its maximum on about the eleventh day in each case. As a rule inhibition was more distinct in the conglutination test. The optimum amount of serum required for the conglutination test was 0.05 cc.

The mechanism of the conglutination reaction is discussed.

Johne's disease, A. L. SHEATHER (*Vet. Rec.*, 27 (1914), No. 1375, pp. 276-281).—This paper was presented at the Tenth International Veterinary Congress, held at London in 1914.

The diagnosis of rabies by the detection of sugar in the urine and hemorrhages in the gastric mucous membrane, N. MICHIN (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 35, pp. 622-624).—The tests were made with the urine of rabbits infected with passage or street virus. Sugar was not noted in all of the cases, but the findings of sugar in the urine might, under certain conditions, be used in diagnosing rabies. Hemorrhages in the mucous membrane of the stomach were also noted, but not in all cases.

Experiments on the cultivation of rinderpest virus as described by Baldrey, W. H. BOYNTON (*Philippine Jour. Sci., Sect. B*, 9 (1914), No. 3, pp. 259-268).—In the case of two animals that died in less time than the incubation period of rinderpest after injection of Martin's broth culture, the autopsy

findings of the tissues indicated death from a bacterial infection and not from rinderpest. "All evidence points to the conclusion that the Martin's broth employed in these two cases was contaminated by bacteria prior to injection in the animals. The results are attributed to poor aseptic technique, and greater care in the subsequent inoculations, where no such toxemias were induced in the injected animals, support the conclusion.

"The symptoms, lesions, and other circumstances stated by Baldrey (E. S. R., 27, p. 380) resemble the results obtained in the two animals in question, and there is justification for belief that his results were due to the same cause. In all the other animals injected with mixtures of blood and culture medium after incubation, no immediate ill effect followed, in either susceptible or immune animals.

"With the exception of the animals noted . . . all those injected with the so-called 24 and 48 hour cultures of rinderpest in neutral or alkaline Martin's broth contracted rinderpest after the usual incubation period and died. These observations do not support Baldrey's belief that there occurs a rapid formation of rinderpest toxin in the broth during the 24 hours with resulting death of the virus. The experiments have included tests of Martin's broth after incubation as long as 72 hours. Rinderpest virus does die in Martin's broth culture after incubation for 72 hours, but there is no evidence that rinderpest toxin was formed, much less that rinderpest toxin caused the death of the virus.

"The experiments reveal the fact that rinderpest virus will survive in neutral or alkaline Martin's broth at 37° C. for at least 48 hours, but not for 72 hours. Two cases were tested at 24 hours, two at 48 hours, and three at 72 hours. Rinderpest virus kept in acid Martin's broth or in 5 per cent potassium citrate solution did not survive after 48 hours at 37°."

Abderhalden's dialysis method in pulmonary tuberculosis, M. WOLFF and K. FRANK (*Berlin. Klin. Wechnschr.*, 51 (1914), No. 19, pp. 875-877).—The tests were conducted with the sera of man and the substratum employed was prepared from tuberculous lung, tubercle bacilli, normal lung, dog's lung, or human muscle. It is concluded that the test in its present form can not be considered of value for diagnostic or prognostic purposes.

Experimental studies on blood serum of cows immunized against tuberculosis, E. R. BALDWIN (*Arch. Int. Med.*, 13 (1914), No. 5, pp. 682-700; *abs. in Jour. Amer. Med. Assoc.*, 62 (1914), No. 23, p. 1842).—These experiments relate to the properties of the serum of a cow repeatedly immunized against tuberculosis over a period of ten years. The cow was given six intravenous injections of living human tubercle bacilli, both virulent and slightly virulent, besides numerous injections of various forms of tuberculin. Specific agglutinins, opsonins, and complement-fixing antibodies were developed in the serum, but never to a very great degree. Bacteriolysin was never noted nor was a bacillicidal effect recognized in either the serum or leucocytes.

"Living human tubercle bacilli 'sensitized' with the immune serum showed increased infective power in guinea pigs and rabbits as compared with normal cow serum. The increased infective power was manifested by earlier and more marked reactions or inflammation following inoculation, and a wider spread of the disease than in controls. This acceleration of infection was not manifest unless the cow had recently received injections of pulverized bacillus residue, but the immune serum agglutinin titer was not always greater than the normal cow serum. To explain the apparent paradoxical action of the immune serum, it is suggested that the strongly agglutinated bacilli were protected from injury by the leucocytes of the inoculated animal by reason of the clumping. The bacilli were presumably phagocyted in large masses, but more difficult of diges-

tion for that reason. It may also be suggested that the bacilli laden with antibody (opsonin) were more rapidly phagocyted and scattered, but owing to the resistant wax were not digested in sufficient numbers.

"A sensitized living tubercle bacillus vaccine is not safe or practicable when prepared from immune bovine serums, considering the above-mentioned results."

Concerning the occurrence of nongas-producing paracolon bacilli in cases of paracolon bacillosis of calves, M. CHRISTIANSEN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 74 (1914), No. 5-6, pp. 474-481).—A nongas-producing bacillus of the enteritidis subgroup closely related to the paracolon bacillus was found by the author to be the cause of bacillosis in 19 calves from 10 different herds.

What is hog cholera? K. SCHERN and C. STANGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 2, pp. 107-116).—At the present time much confusion prevails as to what constitutes hog cholera. In this article an endeavor is made to analyze the subject from various view points. Generally speaking, it is the disease caused by a mixed infection, namely, filterable virus and *Bacillus suispestifer*. The virus is in most cases the primary cause of the disease, and from a practical standpoint we could almost say "no filterable virus, no hog cholera."

The following classification is suggested: (a) Pest, the disease caused by virus and *B. suispestifer* and other bacteria; (b) para pest, caused by *B. suispestifer* and other bacteria; and (c) virus pest, the disease caused by the filterable virus.

The hog-cholera problem, K. SCHERN and C. H. STANGE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 5, pp. 341-349).—At the outset objections are raised against the use of the term shoat typhoid (Ferkeltyphus), in this respect the authors agreeing with Miessner. The Glässer bacillus and *Bacillus voldagsen* belong to the pestifer group, and at the present time they are of no more significance than *B. suispestifer*. In Iowa there are many cases which at first sight might be considered cases of so-called shoat typhoid (E. S. R., 32, p. 378), but on closer study one finds that the filterable virus also has a hand in the infection. A clinical and pathological distinction between shoat typhoid and hog cholera is difficult to make. Shoat typhoid is not a new disease in pigs and belongs to the form described as parapest. See above.

Hog cholera and its suppression in North America, K. SCHERN (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 46, pp. 756-759, figs. 2).—An abstract of the article noted above.

Preventive measures other than vaccination in combating hog cholera, N. S. MAYO (*Amer. Jour. Vet. Med.*, 9 (1914), No. 7, pp. 481-483).—The author maintains that in spite of the general and extensive use of antihog-cholera serum, the animal losses from hog cholera are greater than before the introduction of the serum treatment. He suggests that sick hogs be given a good purge of salts, followed with intestinal antiseptics freely, such as sulphocarbolates, salicylic acid, naphthalin, turpentine, and carbolic acid. "The hygiene and diet should be carefully regulated, as provided for the isolated hogs showing no symptoms of disease. This treatment should always be given, even if serum is administered. The quarters must be cleaned and disinfected and all dead animals burned or buried deeply. It is not claimed that this treatment is a specific for true hog cholera, but it is a valuable adjuvant to the serum treatment for the filterable virus disease, and it is a practical, economical, and successful treatment for some swine diseases that closely resemble true cholera in both symptoms and post-mortem lesions.

"A large percentage of losses from hog cholera can be prevented. A strict quarantine against all transmissible swine diseases should be maintained and the general health of swine should be preserved by clean, comfortable quarters.

Avoid bedding hogs with old straw that is easily broken up into a fine dust that causes much irritation of the respiratory passages when inhaled. If there are hog wallows, keep them as clean as possible and disinfected. A better way is to have a cement wallow that can be cleaned and supplied with fresh water, to which a nonpoisonous disinfectant can be added. Swine should have a variety of good food, with good pasture when possible, and plenty of mineral elements supplied. Above all, keep the quarters clean. . . .

"The past three years of disaster should convince the skeptical that something beside antihog-cholera serum, as it has been used, is needed to control swine diseases."

Inoculation against swine fever, F. HUTYRA (*Deut. Tierärztl. Wchnschr.*, 22 (1914), No. 31, pp. 489-493; *abs. in Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 42, p. 708; *Amer. Vet. Rev.*, 46 (1914), No. 2, p. 196).—The author believes that hog cholera may be successfully combated by injecting serum and by simultaneous inoculations.

"A potent serum confers immunity against both experimental and natural infection with the filterable swine fever virus, and indirectly against secondary bacterial infections (mixed infections). Animals that are injected with serum and simultaneously or shortly afterwards exposed to natural infection acquire a permanent active immunity. Serum injection is therefore indicated in the case of recently infected premises, and if the injections are made as soon as the presence of the disease is recognized they have the effect of rapidly cutting short the outbreak. By the simultaneous methods pigs immediately acquire an active immunity which is lifelong. On previously healthy premises the simultaneous method, as a rule, causes little or no loss, but excessively severe inoculation reactions can not be avoided. Until the inoculation reactions are passed great care must be exercised to prevent the spread of the disease."

The paratyphoid bacilli of abortion in mares, T. VAN HEELSBERGEN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 16 (1914), No. 3, pp. 195-201).—A discussion of the probable relation of the paratyphoid bacilli described by various workers as the cause of abortion in mares.

A reinvestigation of Konew's protective vaccination against the pectoral form of influenza in horses, THIENEL and JÄGER (*Ztschr. Veterinärk.*, 26 (1914), No. 3, pp. 125-131; *abs. in Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 33, pp. 601, 602).—Konew's vaccine is directed against the disease caused by the *Bacillus pleuro-pneumoniæ contagiosa equorum*. The horses treated by the vaccine did not react except in a few instances where there were temperature rises of from 0.3 to 0.5 cc. The micro-organisms isolated by Konew could not be found in the blood stream of animals affected with the typical form of the disease. An immunity was not produced in the animals and from 45 to 66 per cent died from typical influenza. Horses reinfected with the disease showed no improvement after being given the vaccine. It is believed that good results can be obtained with Konew's vaccine only in those establishments where the disease has been prevalent for a long time and where the larger number of the horses have gone through the cycle of the infection.

RURAL ENGINEERING.

The flow of water in irrigation channels, F. C. SCOBAY (*U. S. Dept. Agr. Bul.* 194 (1915), pp. 68, pls. 20, figs. 9).—This bulletin, treating the subject of the flow of water in irrigation channels, is based on extensive field tests made for the purpose of determining the proper values of the retardation factor in Kutter's formula under various conditions found in practice.

Tests were conducted in 10 States on channels ranging in size from small ditches carrying less than 1 second-foot up to canals carrying over 2,600 second-feet. The materials of these channels comprise wood, concrete, earth, rubble masonry, cobblestones, and a few special combinations. Test data were also obtained from other sources in cases where in the author's opinion there was not sufficient evidence obtained from his own experiments to warrant the drawing of conclusions.

The following conclusions are drawn from a study of the experiments and the data as assembled: "Kutter's formula is applicable to the design of any open channel. The recommendations of the earlier writers concerning the values of n to be chosen were in the main correct. Any weakness was due to the fact that there was not sufficient distinction made between the various categories and that materials of construction are now used which were not covered by the tests from which early deductions were made. The influence of curves was not as a rule included. Concrete lining covered but one value of n , whereas in practice there are many shades of roughness, all applicable under the general head of concrete. The factor n must include all the influences which tend to retard velocity. The principal of these influences are undoubtedly (a) rubbing friction between the water and the containing channels, and (b) vegetable growth extending into the main body of the water. . . . Of secondary importance but nevertheless deserving of careful consideration in about the order named are the following: (c) Angles and sharp curves in the alignment, (d) influences which tend to disturb parallel filaments of current, . . . (e) sand and gravel, . . . [and] (f) the prevailing wind direction. . . . There is a tendency toward a lower value of n as the velocity and hydraulic radius increase. . . . A value of n must be chosen that will apply to the canal in question at the critical period of the season. . . . In the design of earth channels having a trapezoidal form when constructed, the value of [the hydraulic radius] should be computed on the basis that the canal takes an elliptical form within a short time and thereafter maintains this shape unless altered artificially."

The values recommended for n in Kutter's formula, which are applicable for velocities up to about 5 ft. per second and with hydraulic radii to about 2 ft. are as follows:

For concrete lining "(1) $n=0.012$ for the highest grade of material and workmanship and exceptionally good conditions. The surface of the lining to be as smooth to the hand as a troweled sidewalk. The expansion joints to be so well covered that they practically fulfill the same condition. The climate and water to be such that moss does not accumulate to any great extent. The water to be practically free from shifting material. The alignment to be composed of long tangents, joined by spiraled curves, while the interior of the channel must be of uniform dimensions, true to grade throughout the cross section. (2) $n=0.013$ for construction as in type (1), but with curves as in the usual mountain canyon. Same construction and alignment as in type (1), but with small amount of sand or débris in water. Construction as in type (3), but in very favorable alignment or for water that carries a small amount of fine silt that will eventually form a slick coat. (3) $n=0.014$ for linings made by good construction under favorable conditions. The surface to be as left by smooth-jointed forms or to be roughly troweled. Joints to be good, but causing some retardation. Alignment about equal in curves and tangents, with no spirals between. The bed to be clean and sides free from rough deposits. . . . (4) $n=0.015$ for construction as in type (3), but with sharp curves and clean bottom or moderate curves and much débris on the bottom but clean-cut sides. (5) $n=0.016$ for concrete as constructed by the average

gang of laborers, using forms that leave prominent lines at the cracks, no finish coat being applied. Bed to have the usual small amount of rock fragments and patches of sand and gravel. Average amount of curvature. . . . (6) $n=0.017$ for roughly coated linings with uneven joints. This value also is applicable where rough deposits accumulate on the sides and conditions of alignment are poor. (7) $n=0.018$ for very rough concrete with sharp curves and deposits of gravel and moss. A broken gradient, irregular cross section, and the like, contribute to such a high value of n ."

For wooden flumes "(1) $n=0.012$ for well-constructed, clean flumes with surfaced lumber for both siding and battens. All lumber to run longitudinally. Alignment to consist of long tangents, with gentle curves between. Construction to be such that the grade line will remain uniform, preventing sags and wavy alignment. . . . (2) $n=0.013$ for well-constructed, clean flumes of surfaced lumber and battens, following mountain contours, where the alignment will consist of about equal gentle curves and tangents. . . . (3) $n=0.014$ for flumes of very smooth interior, but with many bends or sharp curves. . . . (4) $n=0.015$ for flumes of unplanned lumber, but otherwise as of type (2). . . . (5) $n=0.016$ for flumes of type (4) where sharp bends rather than curves are installed. For flumes lined with rough roofing material and for the ordinary grade of construction on a flume that is built and generally left to care for itself."

With reference to masonry lined channels, it is stated that "if [the bottom] be of smooth concrete and the sides are reasonably smooth, then the value of n approximating that in average concrete may be used."

For earth channels "(1) $n=0.016$ for excellent conditions of earth channels. The velocity to be so low that a slick deposit of silt may accumulate or the natural material be such as to become smooth when wet. The influence of vegetation at the edges to be a minimum. The water to be free from moss and other aquatic growth. The alignment to be free from bends and sharp curves. (2) $n=0.02$ for well-constructed canals in firm earth or fine, packed gravel where velocities are such that silt may fill the interstices in the gravel. The banks to be clean-cut and free from disturbing vegetation. The alignment to be reasonably straight. (3) $n=0.0225$. . . for the average well-constructed canal in material which will eventually have a medium smooth bottom, with graded gravel, grass on the edges, and average alignment or silt at both sides of the bed and scattered stones in the middle, or a smooth bottom with an average amount of grass and roots forming the sides. Hardpan in good condition, clay, and lava-ash soil take about this value. (4) $n=0.025$ for canals where the retarding influence of moss, growths of dense grass near the edges, or scattered cobbles begins to show. . . . (5) $n=0.03$ for canals subject to heavy growths of moss or other aquatic plants. Banks irregular or overhanging with dense rootlets. Bottom covered with large fragments of rock or bed badly pitted by erosion. Values of n between 0.025 and 0.03 also cover the condition where the velocity is so high that cobbles are kept clean and unpacked in the center of the canal, but silt deposits near the sides."

For cobble bottom canals it is stated that "where the cobbles are graded in size and well packed the value of n is about 0.027, but the value rapidly increases as the larger rocks predominate and the lack of graded sizes prevents packing."

The values of n for metal flumes are given in a previous report by Cone, Trimble, and Jones (E. S. R., 30, p. 885).

Two sets of curve charts to aid in the design of irrigation channels are also included. An appendix contains abstracts of descriptions of canals on which similar tests have been made in recent years by other agencies than this office.

Ground water for irrigation in the Sacramento Valley, California, K. BRYAN (*U. S. Geol. Survey, Water-Supply Paper 375-A (1915), pp. IV+49, pls. 2, figs. 6*).—This report, prepared in cooperation with the department of engineering of the State of California, describes the geography and geology and deals with the ground water resources of an area in California containing 15 per cent of the agricultural land of the State, with reference to their development and use for irrigation.

“The valley includes (1) sloping plains, (2) shallow basins of heavy soils, (3) low ridges of loam and silt soils along the rivers, and (4) higher plains of older alluvium laid down during a previous cycle of deposition and now raised above the valley floor in low hills and rolling plains. . . . Throughout the valley the alluvium at a depth of a few feet is saturated with water. . . . The water table slopes from the sides of the valley toward the center and from the north to the south. The grade is slightly less than that of the land surface, so that water is shallower in the basin area than toward the hills. . . .

“Although there are large areas in the valley with a shallow water table, favorable to evaporation and the accumulation of alkali, only comparatively small areas are unfitted for agriculture from this cause.” This is explained as follows: (1) The ground waters are of good quality. . . . (2) The water table is very flat over the basins, and movements of the ground water are sluggish. Water is supplied more freely at the bases of the slopes, and for this reason the principal concentration of alkali occurs at the edges of the basins. This is particularly the case on the west side, where alkaline patches and areas of salt grass border the basin along its western edge. . . . (3) The heavy winter rains leach out much of the salts concentrated at the surface. Similarly flood waters wash out the salts in overflowed lands, and on the edges of the plains the same waters deposit mud or sediment, which often covers up the alkali.”

The fluctuations of the water table are said to be large. “The total quantity of ground water in the valley is very great. The sands and gravels contain from 20 to 40 per cent of water, the clays perhaps more. Because the pore spaces of the sand and gravel are much larger than those of the clay the rate of flow through these materials is much greater and they become for practical purposes the water bearers. The sand and gravels are distributed through the alluvium, which thickens from less than 50 ft. at the edge of the valley to 500 ft. or more in the center. . . .

“Observations show that pumping produces only a local depression of the water table, and that the winter rise in normal years is rapid and effective. General lowering of the ground water may be expected in the summer, and it will be large during periods of deficient rainfall. Heavy pumping may be expected to create still further depression, which, if the whole valley were irrigated by pumping, would increase the general lowering. . . . In view of the high lifts common in southern California, where water is being pumped for irrigating alfalfa with a lift of 100 ft. and for irrigating citrus fruits with a lift of 200 to 400 ft., it would seem that a very considerable increase in the number of plants can be made in the present pumping districts of the Sacramento Valley. . . . Although it is possible from geologic evidence to determine for any part of the valley the general distribution and character of the water-bearing beds, the precise location of these beds and their value as sources of water can be determined only by sinking wells.”

Considerable general information is given relating to well sinking and the pumping and distribution of irrigation water.

Statistics of ground water irrigation in the valley gathered by the author indicate that there are 1,664 pumping plants irrigating a total area of 40,859

acres. The total power is 15,142 horsepower, of which 10,685 horsepower is electrical and 4,457 horsepower is internal combustion or steam power. The average power per plant is 9.1 horsepower, and the average area irrigated for each plant is 24.5 acres.

Ground-water resources of the Niles cone and adjacent areas, California, W. O. CLARK (*U. S. Geol. Survey, Water-Supply Paper 345-H (1915)*, pp. IV+127-168, pls. 9, figs. 16).—This report, prepared in cooperation with the department of engineering of the State of California, deals with the physiography, geology, and ground-water resources of an intensively cultivated area of 20,800 acres in the Santa Clara Valley, Cal.

“The ground water in the vicinity originates in the rain that falls upon the drainage basin tributary to this part of the Santa Clara Valley and to a small extent in the rain that falls upon the valley itself. The Niles-Irvington fault, which cuts off the reentrant of the valley between Niles and Irvington, has a profound effect on the surface drainage and on the circulation of the ground water. . . . It has also produced an underground dam which prevents the passage of ground water from the east to the west side of the fault except in small amounts. . . .

“The annual contribution of ground water to the Niles cone and the adjacent area under consideration west of the fault is believed to range between 2,600 and 59,000 acre-feet, or between somewhat wider limits, exclusive of the withdrawals during the replenishing period. . . . The estimated annual requirement of ground water for irrigation of all crops now grown on the Niles cone and on the adjacent area supplied by Alameda Creek west of the fault is between 16,000 and 24,000 acre-feet, the smaller quantity being approximately that now used for irrigation and the larger quantity that which will be required in the future. . . .

“The ground-water supply of the Niles cone and the adjacent area west of the fault is little, if any, greater than the amount required by present developments and is hardly adequate for the full irrigation of the area and the present-scale diversions by the Spring Valley and People’s water companies. If further diversions are necessary for public supplies of San Francisco or the transbay cities, irrigation developments will probably have to be arrested unless provision can be made for conserving and utilizing the flood water which now runs to waste.

“The north end of the valley area east of the fault has a larger ground-water supply in proportion to its extent than the area west of the fault. Its supply is believed to be at least adequate for the irrigation of the arable land that it contains, but the portion of this area from the vicinity of The Lagoon southward is underlain by material that in general yields water too slowly for irrigation. There is little danger, even with heavy pumping, that the area under consideration will be seriously damaged by the encroachment of sea water.”

Gazetteer of surface waters of Iowa, W. G. HOYT and H. J. RYAN (*U. S. Geol. Survey, Water-Supply Paper 345-I (1915)*, pp. 169-221).—This gazetteer embraces descriptions of all the streams named on the best available maps of Iowa.

Surface water supply of Ohio River basin for the year ended September 30, 1913, A. H. HORTON, W. E. HALL, and H. J. JACKSON (*U. S. Geol. Survey, Water-Supply Paper 353 (1915)*, pp. 264, pls. 5).—This report, prepared in cooperation with the State of West Virginia, presents the results of measurements of flow made on streams in the Ohio River basin during 1913.

Surface water supply of St. Lawrence River basin, 1913 (*U. S. Geol. Survey, Water-Supply Paper 354 (1915)*, pp. 136, pls. 2).—This report, prepared in

cooperation with the States of Minnesota, New York, and Vermont, presents the results of measurements of flow made on the streams in the St. Lawrence River basin in 1913.

The utilization of the subterranean reservoir of Egypt, V. M. MOSSERI (*Bul. Union Agr. Égypte*, 12 (1914), No. 104, pp. 61-97, pls. 3).—The author reports an investigation of the underground waters of Egypt, and concludes that the quantities of subterranean water potable and suitable for irrigation that are lost annually to the sea during low water are immense. It is pointed out that Egypt could profitably use a part of this water either for extending summer cultivation or to obtain in certain years a quantity of water sufficient to provide the complement of water which the Nile has been unable to bring down at the time.

The author proposes that the Egyptian Government develop the subterranean water supply and suggests to this end that a subterranean barrier, consisting of a network of deep wells, be constructed to parallel the Mediterranean coast at a distance of 80 km. (50 miles) from it. He estimates that such a barrier will prevent the loss of the underground water to the sea and will conserve for use 1,500,000,000 cubic meters of water in the period extending from March to August. A quantity of water also will be placed at the disposal of a part of Egypt sufficient to provide the amount needed during the time of the winter cleaning of the canals. It is believed that the deduction of 1,500,000,000 cubic meters of water will hardly affect the subterranean flow of water toward the Nile during low water nor the amount needed by plants.

It is further shown that the natural subterranean water added to the water of the Nile is suitable for irrigation purposes, and that the cost of its elevation with proper and satisfactory apparatus is not excessive.

The value of large zinc pipes for carrying water, A. RINCK (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 28 (1914), No. 2, pp. 99-103; *abs. in Chem. Zentbl.*, 1914, II, No. 13, p. 844).—Experiments showed that with long-continued exposure to water the zinc acquired a coating of basic carbonate, which rendered it considerably less soluble. After such pipes had been used a year, the solubility of the zinc varied from 2 to 3 mg. per liter of water remaining in contact with the zinc for several months.

Note on the bacteriotoxic action of water, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 39 (1914), pt. 3, pp. 533-537).—Experiments in which suspensions of *Bacillus prodigiosus* and *B. typhi* were added to tap water, boiled and unboiled, and filtered through a Chamberland filter, showed that, as a rule, the growth of the organisms was retarded, especially in the case of the boiled water. The conclusion is reached that "ordinary tap water contains substances of the nature of bacteriotoxins, the toxicity of which is increased by boiling."

Watering devices for moorland pastures, VON SCHMELING (*Mitt. Ver. Förd. Moorkultur Deut. Reiche*, 32 (1914), No. 21, pp. 390-393, figs. 2).—Arrangements for obtaining clean water for stock are described.

The drainage of Jefferson County, Texas, H. A. KIPP, A. G. HALL, and S. W. FRESCOLN (*U. S. Dept. Agr. Bul.* 193 (1915), pp. 40, pls. 2, fig. 1).—This bulletin reports the survey and plans for the drainage of an area of about 612,000 acres in southeast Texas, the survey being completed December 1, 1912.

The topography of the area is generally flat and level, with few unusual physical features. The predominating surface soils are fine sandy loams, loams, clay loams, silt deposits, and muck, and all are underlain by a deep stratum of clay. Limited areas of fine sand also occur in certain parts of the county.

From observations of run-off and a consideration of factors affecting the same in the area it is thought advisable to design the drainage improvements

to care for the run-off from a rainfall of 4 in. in 24 hours. A formula suggested by one of the authors for computing the run-off depth to be expected from any simple drainage area is as follows:

$$D = CM\sqrt{PF} \frac{(B+L)^{\frac{3}{2}} - (B^{\frac{3}{2}} + L^{\frac{3}{2}})}{BL},$$

in which D = maximum rate of run-off, in inches per 24 hours, to be expected from the rainfall P ; C = a coefficient depending solely upon the physical character of the soil, and determined by experiment; M = the ratio of total run-off to total rainfall for the precipitation P , varying with evaporation, deep percolation, lateral seepage from the drainage channels, and duration of flood; P = the depth of rainfall in inches in 24 hours (4 in. for Jefferson County); F = the average slope of the ground surface of the drainage area, in feet per mile; L = the mean length of the drainage area in miles; and B = one-half the mean width of the drainage area in miles. For drainage areas that contain storage reservoirs, a special calculation must be made to eliminate the effect of the reservoirs. Where the main watercourse is formed by the junction of two or more large tributaries, the formula is to be applied to each tributary separately, and the proper value of the run-off depth for the entire area will be the weighted mean of the values for the parts. . . .

"The general plan proposed for the drainage of that part of Jefferson County which can be wholly or partially drained by gravity consists in (1) dividing that part into its natural drainage units, (2) straightening and enlarging all the present water courses that will become the main outlets or arteries for a complete drainage system, and (3) constructing systems of parallel ditches, spaced one-half mile apart and running generally with the greatest slope of the land, reaching to the boundaries of each district. The plan proposed for the remainder of the county consists in (1) dividing it into convenient pumping districts, (2) straightening and deepening certain water courses and constructing the proposed Intercoastal Canal, all of which will serve as outlets for the pump discharges, (3) building levees to prevent the overflow of those districts by tides, backwater from the river, or run-off from higher lands, (4) constructing systems of parallel ditches spaced 1 mile apart and reaching to all parts of each district, and (5) erecting pumping plants to lift the water from such inclosures over the protection levees."

The proposed plan of drainage includes thirty-two drainage districts and water areas and areas outside of the districts covering 17,590 acres, all areas totaling 611,900 acres of which 530,670 acres will be benefited. The plan makes necessary 1,630.3 miles of ditches and the total cost is estimated at \$5,598,249 or \$10.55 per acre.

Road building in swamps, E. KRÜGER (*Mitt. Ver. Förd. Moorkultur Deut. Reiche*, 32 (1914), No. 18, pp. 353-357).—Problems involved in the construction of roads in swamp land under different conditions of drainage are discussed.

Machinery for construction and maintenance: State, municipal, contractors, traction haulage of stone, care of machinery; instructions to engineer and operator, T. R. AGG (*Good Roads, n. ser.*, 9 (1915), No. 1, pp. 21-24, figs. 2).—Principles applicable to the selection, operation, and maintenance of road-building machinery are discussed.

Motor-vehicle registrations and revenues, 1914 (*U. S. Dept. Agr., Office Sec. Circ. 49* (1915), p. 1).—This report, prepared by the Division of Road Economics of the Office of Public Roads of this Department, gives data for each State with reference to the 1,666,984 automobiles, 44,355 motor trucks, 152,945 motor cycles, and 1,812 cars for hire, licensed in 1914, the number of operators'

licenses, and the revenues. The total fines amounted to \$101,364, and the gross registration revenues to \$12,270,035.78.

Trial of machine plowing in rice fields, A. TARCHETTI (*Gior. Risicult.*, 4 (1914), Nos. 5, pp. 65-80; 7, pp. 103-107; 8, pp. 122-128; abs. in *Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 9, pp. 1207-1209).—Trials of mechanical cultivation in rice fields in which eight machines competed are reported. The machines included motor-hauled plows, self-contained motor plows, cable-hauled plows, and rotary diggers. The average length of furrow was about 1,000 ft. and a plat of about 7½ acres was assigned to each machine. Of the cable-drawn outfits, one with a 13-horsepower oil motor and a two-wheeled windlass truck was given first place. Of the direct traction outfits, one with a 24-horsepower motor was given first place.

Manila-rope fastenings (*Engin. Rec.*, 70 (1914), No. 26, p. 706, figs. 7).—Tests to destruction of nine ordinary methods of fastening manilla rope with reference to tensile strength indicated that eye-splices are the most satisfactory, considering the high strength they develop and their relative cost.

RURAL ECONOMICS.

Rural social problems, C. J. GALPIN (*Bul. Univ. Wis. No. 711* (1914), pp. 51, figs. 23).—This is the report of the fourth annual country-life conference of Wisconsin and presents a digest of significant facts, methods, and enterprises discussed.

Country-life week (*Ohio State Univ. Bul.*, 19 (1914), No. 3, pp. 5f).—The addresses at this conference related to the shifting of the rural population, relationship between the church and rural problems, and recreational and social needs of rural communities.

The church at the center, W. H. WILSON (*New York: Missionary Education Movement of the United States and Canada, 1914*, pp. 98, pls. 4, figs. 2).—This book outlines the function of the country church and indicates, by citing typical instances, how the church has been used as a means of improving rural conditions.

The making of a country parish, H. S. MILLS (*New York: Missionary Education Movement of the United States and Canada, 1914*, pp. XVIII+126, pls. 4, fig. 1).—There is given in this book the history of the development of a country parish at Benzonia, Mich. The organization as finally developed consisted of a large, central congregation with a number of branches conveniently located to the farm homes in other parts of the parish, but closely related to the central congregation in all of their activities.

Working and living conditions of women employed in agriculture, H. SEUFERT, ELLY ZU PUTLITZ, and PRIESTER (*Schr. Aussch. Förd. Arbeiterinnen-Interessen, 1914*, Nos. 4, pp. XII+355; 5, pp. 169; 6, pp. 213).—These reports describe the conditions existing in Wurttemberg, Baden, Alsace-Lorraine, Rhine "Pfalz," Mecklenburg, and Brandenburg among the native and foreign hired women agricultural workers, and of the wives and daughters of the small farmers. They note the influences of trade conditions and of the factory and household industries, and the possibilities of bettering the condition of these classes.

Report on home industries in the highlands and islands (*Rpt. Bd. Agr. Scot., Home Indus. Highlands and Islands, 1914*, pp. IX+207, pl. 1, figs. 12).—This report shows the development of home industries beginning with the fifteenth and sixteenth centuries, describes the function of home work in connection with tweed manufacture, Shetland hosiery, lace making, wickerwork, basket making, and kelp gathering, and points out the function of the board of

agriculture in improving these industries and the effects of the truck system. The report, in commenting on the effect of rural home industries upon the economic life of the people, says: "Where the crofts are small or poor, and where there is a large cottar population, home industries are necessary for the support of the people, while any considerable extension of such occupations will have a material effect in raising the standard of comfort. The nature of the work in the vicinity of the home constitutes adaptation of the people to a refinement which, from the point of view of agricultural production, is an unkindly one."

Abandoned and unoccupied farms for sale in Pennsylvania, N. B. CRITCHFIELD and L. H. WIBLE (*Penn. Dept. Agr. Bul. 252 (1914), pp. 48, pls. 3*).—This bulletin contains a list of farms for sale, together with a description showing the location in regard to schools and markets and the character of the land and buildings.

International annual of agricultural legislation (*Inst. Internat. Agr. [Rome], Ann. Internat. Leg. Agr., 3 (1913), pp. VI+1113*).—This report contains abstracts and quotations of laws with references, concerning methods of gathering agricultural and commercial statistics; the regulation of commerce in agricultural produce, fertilizers, and live stock; appropriations for agricultural purposes; taxation and exemption of agricultural property; regulations concerning the production of plants and animals and industries connected therewith; control of plant and animal diseases; cooperative organization, insurance, and agricultural credit; relationships of the agricultural landowner, tenant, and laborers; rural sanitation; and police duties in rural districts.

Rural credits in Ireland, W. FROST (*U. S. Senate, 63. Cong., 2. Sess., Doc. 607 (1914), pp. 12*).—This contains a review of the report already noted (*E. S. R., 32, p. 286*).

Long-time farm loans, B. B. HARE (*U. S. Senate, 63. Cong., 2. Sess., Doc. 421 (1914), pp. 12*).—The author has outlined the system of extending credit to farmers as found in New Zealand. This country issues and sells bonds, the proceeds from which are loaned to settlers for periods varying according to the character of the security offered. He points out how the system might be adopted in South Carolina, and that it is in effective operation in eight American States.

Cotton warehouses: Storage facilities now available in the South, R. L. NIXON (*U. S. Dept. Agr. Bul. 216 (1915), pp. 26*).—The author concludes that in storage capacity the present warehouses are ample, but that these warehouses are poorly distributed. The best warehouses are not available to farmers. The dealers or middlemen not only control the best storage houses but have better financial connection. He calls attention to the fact that a large standard storage house pays ample dividends while many of the owners of small warehouses actually lose money on their investment. He considers it desirable that the farmers cooperate in building their own warehouses, and advises that all warehouses should conform fully to the standards recognized by the underwriters' associations, as this will save cost in construction, in handling, and in insurance. A proper system of warehouses would simplify the financial system and eventually free the southern cotton farmer from the present disastrous credit system. He also believes that cotton mills should encourage storing by paying a premium for cotton in good condition. The estimated number of warehouses in the cotton belt at the beginning of the 1913-14 season was 3,145, with a storage capacity of 9,344,520 bales, flat; 12,486,920 bales as offered, or 15,738,825 bales compressed.

A system of accounting for cooperative fruit associations, G. A. NAHSTOLL and W. H. KERR (*U. S. Dept. Agr. Bul. 225 (1915), pp. 25*).—There is outlined

in this bulletin a system of accounting devised to meet the requirements of the smaller organizations handling deciduous fruits and produce on a commission basis. Inasmuch as the organization acts in the capacity of an agent for the growers, the author claims the accounting system should be so arranged that the history of each lot of fruit or produce delivered can be easily and quickly traced from the time it is turned over to the organization for shipment until the returns are paid to the producer. The system provides for the filing together of all papers pertaining to the same shipment in a separate folder or envelope where they will be readily accessible for reference. They are kept in this folder or envelope until the receipt of the remittance from the sales is received. The accounting system calls for nine forms, as follows: The receipt, the manifest, the bulletin, the invoice, the car envelope, the journal, the record of cash, the account sales, and the ledger. The bulletin indicates how the books are to be set up and closed and the function of each form in the accounting system.

A system of accounts for farmers' cooperative elevators, J. R. HUMPHREY and W. H. KERR (*U. S. Dept. Agr. Bul. 236 (1915), pp. 30*).—This bulletin outlines a system of accounting for cooperative elevators in which the complete system will require fifteen forms, as follows: (1) Cash, journal, purchase and sales record; (2) record of grain receipts; (3) record of grain purchases; (4) record of grain shipments and sales; (5) record of hedges; (6) record of sales to arrive; (7) patronage ledger; (8) grain and merchandise report; (9) manager's report; (10) grain check; (11) scale ticket; (12) storage ticket; (13) sales ticket; (14) cash receipt; and (15) cost analysis. The author gives the forms, together with a brief statement of the function of each form and how it is to be used.

The agricultural outlook (*U. S. Dept. Agr., Farmers' Bul. 672 (1915), pp. 28*).—This number shows the estimated condition of winter wheat and rye on April 1, 1915, the approximate commercial apple crop of 1914, condition of apples in cold storage April 1, 1915, and progress of the apple movement, condition of Florida and California crops, trend of prices of farm products, and losses and condition of live stock.

The 1914-15 beet-sugar crop in the United States amounted to 722,054 short tons, and was produced from 483,400 acres, yielding 5,288,500 tons of beets. The Louisiana cane-sugar production amounted to 242,700 short tons.

According to C. M. Daugherty, the available information indicates that the United States, British India, and Canada have increased their winter wheat acreage about 8,500,000 acres. How much of this increase is offset by a decrease in acreage of the contending countries of Europe is not known, but it is concluded that these various influences are likely to leave the world's wheat acreage little, if any, larger than that of last year. His article concludes with a statement showing the average quantity of wheat, rye, barley, and oats sown per acre in the principal grain-producing countries.

F. Andrews states that a recent inquiry of the Bureau of Crop Estimates shows that the average distance from market is 6.5 miles for farms of the United States. The number of possible round trips per day averages for all farms 2.1, and for the more remote farms 1.6 trips. The average size of a wagonload of cotton in the United States is 3 bales, or 1,500 lbs., while the average wagonload of wheat is 53.5 bu., or 3,200 lbs. He estimates that it would require about 6,358,000 days for one wagon to haul from the farms the marketed portion of an average corn crop, 6,857,000 for wheat, and 2,532,000 for cotton.

T. F. Powell believes that the lack of proper assembling methods is one of the chief difficulties encountered in the successful solution of the marketing problem. In localities where suitable common or cold-storage facilities are

available, the growers of farm products would find the concentration and storage-in-transit privileges two of the most desirable means for bringing about the widest distribution.

Fifth census of Canada, 1911.—**Agriculture** (*5. Census of Canada, 4 (1911), pp. CII+428*).—This volume of the census contains statistical data showing by districts the number of farm holdings, the land classified by tenure and purpose to which devoted, area in crops, number of fruit trees, live stock on farms, and value of land, buildings, implements, crops, and live stock. Comparative data is shown for the larger geographic divisions. A copy of the census schedule is also included.

Report of the department of agriculture of Norway for 1914 (*Aarsber. Offentl. Foranst. Landbr. Fremme, 1914, I, pp. 81*).—This report gives statistical data showing the area and production of crops by minor geographic divisions for 1914, with comparative data for earlier years.

[**Statistics of agriculture in Switzerland**] (*Statis. Jahrb. Schweiz, 22 (1913), pp. 72-91*).—These pages contain statistical data showing by cantons the area, production, and value of the principal agricultural products, the production of butter and cheese, and the number of live stock. See also a previous note (E. S. R., 31, p. 895).

[**Agricultural statistics of Russia**] (*Rec. Données Statis. et Écon. Indus. Agr. Russie et Pays Étrangers, 8 (1915), pp. XIV+640*).—This annual report shows statistical data relating to the area, production, value of the principal crops, the number of live stock, foreign trade, prices, domestic movement of agricultural products, wages of agricultural laborers, and information concerning rural credit and special agricultural industries. This information is by minor subdivisions and for 1913, with comparative data for earlier years.

[**Agriculture in the Commonwealth of Australia**], G. H. KNIBBS (*Off. Yearbook Aust., 7 (1901-1913), pp. 220-385, figs. 6*).—This portion of the yearbook contains information concerning land tenure and settlement, number of live stock, area in crops, and agricultural production. A large number of statistical tables accompany the text which give information for individual States and for a series of years. See also a previous note (E. S. R., 31, p. 492).

Some impressions of agriculture in Australia, A. D. HALL (*Jour. Farmers' Club [London], 1915, Jan., pp. 19*).—This pamphlet contains an address describing the agricultural conditions in Australia as observed by the author, with special reference to methods of carrying on the farm operations, of handling sheep, and of solving farm labor problems. The address is followed by discussions.

[**Agriculture in New Zealand**], M. FRASER (*Statis. Dominion New Zeal., 3 (1913), pp. 1-6, 92-104*).—These pages of the annual statistical report contain information concerning the status of land settlement, production of crops and live stock, and the manufacture of agricultural products.

AGRICULTURAL EDUCATION.

[**Statistics of**] **agricultural and mechanical colleges** (*Rpt. Comr. Education [U. S.], 1913, II, pp. 271-313*).—This chapter contains notes on changes in courses and methods of instruction, gifts, buildings and improvements, and legislative appropriations in 1913 to the land-grant colleges of this country, and a compilation from official sources of general statistics, courses of study, attendance, degrees, value of funds and equipment, revenue and disbursements, and additions to equipment of these colleges for the fiscal year ended June 30, 1913.

Duplication in separate agricultural colleges and state universities, T. H. MACBRIDE (*Trans. and Proc. Nat. Assoc. State Univs. U. S. A., 12 (1914), pp. 163-182*).—The author reviews the beginnings of the three higher state institutions of education in Iowa, viz, the University of Iowa, the State Teachers College, and the State College of Agriculture and Mechanic Arts, and discusses the alleged duplication of work in these institutions. He inquires whether it does not appear that the whole question suggested by the topic, that of duplication in any group of state institutions, “depends entirely upon circumstances; not upon past history alone, but upon present convenience; upon the purpose of the people and the community to be served; upon what you are going to do, as well as upon the resources, wealth, and ambition of the commonwealth itself.”

Rural education, G. PORTS (*So. African Jour. Sci., 11 (1914), No. 3, pp. 57-76*).—In this address before the South African Association for the Advancement of Science the author considers the problem of rural education in elementary and secondary schools and certain aspects of higher education which bear on the problem. He calls attention to the teaching of rural subjects, such as school gardening, nature study, agriculture, and the natural sciences, and the extent to which they are being taught in South Africa, and concludes that the main reforms needed to insure a satisfactory system of rural education in South Africa are (1) “more representation for agriculture and the natural sciences on the university council, (2) that the study of the natural sciences in the university colleges should cease to be discouraged, (3) more departmental instructors in nature study and science in the education departments, (4) more teaching of nature study, school gardening, botany, and zoology, and all on the most approved lines, at the training colleges, (5) a matriculation at least as liberal as the present senior certificate, especially in regard to the natural sciences, (6) more botany and zoology in the secondary schools, and (7) more nature study, both systematic and correlated, and school gardening, in the primary schools.”

Report of an agricultural tour in Europe, America, and Japan during 1912-13, L. C. COLEMAN (*Dept. Agr. Mysore, Gen. Ser. Bul. 4 (1914), pp. 53*).—This bulletin contains an account of general observations in connection with institutions and organizations for the development of agriculture in Europe, America, and Japan, visited by the author with the chief object of studying methods of agricultural education. The results of this study have been previously noted (*E. S. R., 31, p. 296*).

Department of rural and agricultural education (*Addresses and Proc. Nat. Ed. Assoc., 52 (1914), pp. 877-907*).—The papers presented before this department of the National Education Association at its convention in St. Paul, Minn., July 4-11, 1914, included the following:

Rural demonstration schools and study-center work for rural teachers, H. H. Seerley (pp. 878-881).—Accounts are given of the demonstration schools that have been established in ten rural independent school districts to serve as centers for training teachers graduated from the special rural teacher course at the State Teachers College, Cedar Falls, Iowa; and of the teacher study centers organized for the improvement of rural teachers in service.

A beginning in rural high-school work and township supervision, Helene E. Glissman (pp. 882-886).—The development of the community spirit in the past five years by the Garfield Township (Iowa) High School is described.

The use of raw materials in teaching agriculture, W. S. Welles (pp. 886-890).—The author urges a discussion on teaching of agriculture through raw materials and in the field for boys, using the text-book only as a source of help when

needed. Several suggestions are offered in the way of specific direction for such work.

The course in agriculture for training teachers in normal training high schools, J. L. McBrien (pp. 890-895).—In this symposium by educators interested in this subject the following suggestions stand out prominently: (1) The elimination of some subjects from the old traditional high-school course in order to give sufficient time in which to teach manual training, domestic science, and agriculture to the prospective rural teachers in normal training high schools; (2) in order to give agricultural education and rural economics proper dignity in the high-school course, colleges and universities must give due entrance credit therefor when properly taught in the high school; (3) the most available agencies for training teachers for the rural schools are the public high schools that are qualified to give normal training; (4) the proper agencies for training the directors of normal training work in high schools, including the work in agricultural education, are the state normal schools; and (5) the greatest problem in agricultural education is the training of a sufficient number of teachers qualified to give such instruction in rural schools.

The course in agriculture for training teachers in normal training high schools, A. V. Storm (pp. 895-898).—Having reached the conclusion that because of the inability of the normal schools to furnish an adequate supply of teachers for the rural schools, such teachers must be largely prepared by the local high schools, the author discusses the difference in organization of the high-school normal course in various States and the methods of agricultural instruction for rural teachers.

The federated boys' and girls' club work, O. H. Benson (pp. 898-905).—Leadership in country life, club work and its objects, essentials, requirements, and results, evidences of good club work, school extension, school credit for club work, point of view and team work, local organization, club policies, school and home gardens, the need of club leaders, the importance of follow-up work, and the club and the consumer, are considered.

What recognition should be given vacation and other out-of-school work, J. W. Crabtree (pp. 905-907).—The author gives brief statements of the results of school credit for vacation and other out-of-school work and of the reasons justifying such credit. He also describes some of the work for which credit has been given at the State Normal School, River Falls, Wis., including a course of self-boarding, requiring 3 hours each semester in the home economics department, and from 3 to 5 hours' credit on farm practice to boys who spend the vacation at work on the farm, in the dairy, creamery, canning factory, etc.

The use of land in teaching agriculture in secondary schools, E. MERRITT (*U. S. Dept. Agr. Bul. 213 (1915), pp. 12*).—This bulletin is based on questionnaires sent out on the use of land in the teaching of agriculture in the secondary schools, including the advantages and disadvantages and management of the school farm. The data have been previously noted from another source (*E. S. R.*, 31, p. 799).

Suggestions and requirements for teaching of agriculture, manual training, cooking, and sewing in state graded schools, C. P. CARY (*Madison, Wis.: State Dept. Pub. Instr., pp. 48, figs. 10*).—This bulletin contains outlines of work in agriculture, manual training, cooking, and sewing, together with lists of the equipment, reference books, etc., necessary to meet the requirements of the legislative act of 1913 providing \$100 additional state aid for instruction in these subjects in state graded schools in Wisconsin.

Agricultural course for rural high schools (In *A Manual Containing Courses of Study For the High Schools of West Virginia*. Charleston, W. Va.:

Dept. Free Schools, 1912, pp. 60-70).—This is a suggested outline of a 4-year course in agriculture, followed by a more detailed outline of the subject matter for each semester.

Corn and its uses (*Chicago: American Manufacturers' Association of Products from Corn, pp. 12*).—These five lessons on the use of corn and its products have been prepared for the use of colleges and domestic science, normal, and high schools.

Agricultural competition for boys and girls in New York State, E. M. TUTTLE (*Cornell Countryman, 12 (1914), No. 2, pp. 109-115, figs. 4*).—The author discusses the preparation for boys' and girls' agricultural competitions, kinds of contests, follow-up work, and the exhibit and school fair as valuable in the development of country life teaching. "Effort is being made in New York to have the opportunity for better country living opened to all school children as a part of the daily work of the school rather than through isolated clubs." A year ago over 50 of the 207 district superintendents conducted agricultural competitions of some kind, and this year at least half have taken leadership in the movement.

How to organize a club and keep up interest, T. J. NEWBILL (*State Col. Wash. Dept. Ext. Bul. 8 (1914), pp. 15*).—This bulletin discusses the objects to be sought, and offers suggestions for the organization of a club, keeping up interest, prizes, and club meetings. A list of helpful publications is included.

MISCELLANEOUS.

Twenty-sixth Annual Report of Georgia Station, 1913 (*Georgia Sta. Rpt. 1913, pp. 309-319*).—This contains the organization list, reports by the president of the board of directors and the director of the station on its work during the year, and a financial statement for the fiscal year ended June 30, 1913.

Twenty-seventh Annual Report of Georgia Station, 1914 (*Georgia Sta. Rpt. 1914, pp. 259-272*).—Data corresponding to the above are presented for the fiscal year ended June 30, 1914.

Twenty-fifth Annual Report of North Dakota Station, 1914 (*North Dakota Station Rpt. 1914, pts. 1, pp. 21; 2, pp. 41*).—Part 1 of this report contains the organization list, a report of the director, and a financial statement for the fiscal year ended June 30, 1914. The portion of the report on the pure seed law is abstracted on page 138 in this issue.

Part 2 comprises the report of the food commissioner on food, drugs, and sanitation, and is abstracted on page 164.

Java and the Philippines, E. B. COPELAND (*Philippine Agr. and Forester, 4 (1915), No. 1, pp. 1-28*).—An account of the organization of governmental aid to agriculture in Java, based largely on the author's personal observations, and discussed with special reference to conditions in the Philippines.

NOTES.

Maryland College and Station.—William Stanley has been elected a stockholder member of the board of trustees, vice George Calvert resigned. Reuben Brigham, in charge of publications and publicity for the past two years, has been appointed assistant state leader in charge of boys' club work. Kenneth Cole has succeeded W. E. Hanger as assistant in agronomy in the station.

Minnesota University and Station.—Most of the state appropriations have been considerably reduced for the ensuing biennium, the total for the university being about \$1,100,000 less than for the present biennium. The reductions are largely in the appropriations for new buildings and extension work. There is also some reduction in station maintenance which will require the elimination of projects on tobacco, weed eradication, and agricultural engineering. The maintenance appropriations for the substations, however, were increased; at Crookston from \$39,900 to \$45,400, at Morris from \$25,000 to \$34,500, at Grand Rapids from \$7,000 to \$10,000, at Duluth from \$6,100 to \$7,600, at Waseca from \$3,900 to \$4,400, and at the fruit breeding farm at Zumbra, from \$2,000 to \$4,000.

An addition to the home economics building was authorized at a cost of \$45,300, as well as \$30,000 for repairs in the heating plant and \$8,750 for other improvements, including the remodeling of the old home economics building for soils work. A farm engineering building and a dormitory at Morris, to cost \$45,000 and \$15,000 respectively, are provided and \$2,500 for the purchase of additional land. Farm cottages are authorized at Crookston, Morris, and Zumbra. There is \$15,000 for county agent work and \$30,000 for the hog cholera campaign, of which \$10,000 is for alterations in the plant. The total for agricultural work is about \$1,341,050, with \$213,814 additional from federal funds.

Recent appointments include Robert C. Ashby, formerly of the Washington College and Station, as assistant professor of animal husbandry, Jean MacKinnon as assistant professor of nutrition, and Lucile Wheeler as assistant professor of foods and cookery.

Missouri University and Station.—The department of soils has been authorized to locate three additional soil experiment fields, the first on the Lindley loam (the rough timber land) of north central Missouri, the second on the Clarksville silt loam in the south central Missouri Ozarks, and the third on the Waverly silt loam on the lowlands of southeast Missouri.

A summer forestry camp is being maintained on a part of the 50,000 acres of forest land belonging to the university.

Until further notice the hog-cholera serum is to be sold to citizens of the State for immediate use at 1.2 cts. per cubic centimeter, or 1.4 cts. in case the field demonstrator is sent to apply the serum. Dr. J. B. Gingery has been appointed superintendent of the hog-cholera serum laboratory and will have charge of the manufacture and distribution of the serum.

Other appointments include E. H. Rucker and Percy Werner, both 1915 graduates of the university, as assistants, the former in poultry husbandry,

vice C. A. Webster, resigned, and the latter in dairy husbandry. F. L. Duley, who received the master's degree this year, has been appointed research assistant in soils.

Montana College and Station.—Recent appointments effective June 15 include D. C. Wood, a 1915 graduate of the University of Missouri, as assistant professor of farm management and R. S. Jones as assistant in chemistry.

Nebraska University.—R. C. Jensen, instructor in dairy husbandry, resigned July 1 to take up commercial dairy work in South Dakota.

Cornell University and Station.—The legislature has granted increases to the college of agriculture aggregating \$119,557, of which \$66,557 is for maintenance, \$35,000 to complete the heating plant, \$8,000 for the summer school, and \$10,000 for improvements and miscellaneous purposes. This increase will permit of one additional professor, three assistant professors, three instructors, and sixteen assistants on the general staff and one assistant on the extension staff.

The new soils building has been named Caldwell Hall in honor of the late Prof. G. C. Caldwell, professor of agricultural chemistry and chemist for many years. A series of additions to the greenhouses is under construction as well as a tool shed and new pig and sheep barns to cost about \$15,000. Plans are being drawn for the new plant industry building and preliminary plans for a hall of zoology and a rural community service building.

A plan has been ratified for the exchange for one or two terms of instructors with others of equal grade and in similar departments at the University of Wisconsin. One of the objects sought is the furnishing to these men of an opportunity to obtain a wider viewpoint through association with men and methods of another institution.

Instruction is to be offered in bee keeping. Dr. A. A. Allen, an instructor in the arts college, has been appointed assistant professor of ornithology in the college of agriculture, mainly for new courses in economic ornithology.

A. R. Mann has been granted a year's leave of absence for graduate work in the University of Chicago in rural sociology and related lines. He will be succeeded as registrar and secretary by Cornelius Betten, professor of biology and registrar at Lake Forest College. Leave of absence for a half year was granted to Profs. J. E. Rice and W. A. Stocking.

North Dakota College and Station.—E. F. Ladd has been given the degree of LL.D. by the University of Maine.

Pennsylvania College and Station.—Recent appointments include the following 1915 graduates of the college as assistants: Paul S. Baker in agronomy, beginning June 1, and E. R. Hitchner in bacteriology and E. A. Siegler and R. S. Spray in botany, all beginning September 1. W. G. Edwards, who received the degree of master of science in botany this year, has been appointed instructor in botany and forestry beginning July 1, L. O. Overholts, instructor in botany beginning August 1, and A. Leland Beam, teaching fellow in agriculture, beginning September 1.

Tennessee University and Station.—The forty-second annual meeting of the East Tennessee Farmers' Convention was held in the assembly hall on the station farm May 18 to 20 with an attendance of about 2,500. The convention was divided into five sections, namely, live stock, dairy, horticulture, homemakers (women), and boys' corn clubs.

Recent appointments include Oscar M. Watson as instructor in horticulture and horticulturist, and the following members of the extension staff: Hugh Davis Tate, assistant director of agricultural extension; DeWitt T. Hardin, district agent for East Tennessee; James M. Dean, district agent for Middle

Tennessee; Hubert Nichols, district agent for West Tennessee; John C. McAmis, specialist in agronomy; Robert M. Murphy, specialist in animal husbandry; Campbell A. Hutton, specialist in dairy husbandry; Miss Virginia P. Moore, girls' canning club agent; and Leo John Brosmer, specialist in poultry husbandry.

Utah College and Station.—The institution recently celebrated its twenty-fifth anniversary with special exercises and a historical pageant. President Sanborn, the first president and director of the institution, was among those present and participated in the exercises.

An appropriation of \$55,000 for a new chemistry building, made by the legislature two years ago but suspended by the governor, has now been released and the building is under way. An appropriation of \$6,000 for a sewage system and \$30,000 for an addition to the power plant were approved by the governor, but other appropriations were vetoed, including an increase to the station.

The entrance requirements for all college courses have been raised from 14 to 16 units commencing with the present academic year.

Charles W. Porter, who received the Ph. D. degree from the University of California in May, has returned as head of the college work in chemistry. H. W. Stucki has retired on account of ill health and has been succeeded as assistant agronomist by Howard Maughan and he in turn by N. I. Butt of the class of 1915. John Stewart retired at the end of the college year to engage in commercial work.

Lewis A. Merrill, for many years agronomist, but subsequently engaged in commercial work, was killed June 1 in an automobile accident in Salt Lake City. He was a graduate of the college in 1895 and had also studied at the Iowa State College and the Ohio State University. He had been in charge of farmers' institutes and agricultural extension work in Utah, giving special attention to dry farming, and had been professor of animal husbandry in Brigham Young University, editor of several Utah agricultural publications, and prominently associated with the National Dry Farming Congress. He was 41 years of age.

Vermont University and Station.—Walter H. Crockett, for many years editor of several Vermont papers, and for some time official reporter for the legislature, has been appointed editor of university publications, including those of the college of agriculture, the station, and the extension service. G. C. Cunningham, since 1910 associate plant pathologist, has been appointed plant pathologist for New Brunswick and Prince Edward Island.

Washington College and Station.—Dr. J. W. Kalkus, assistant veterinarian, has been appointed veterinarian of the station, vice Dr. S. B. Nelson, who will devote his entire time to his college duties and the secretaryship of the Cascade International Live Stock Association.

Agriculture in the New York Constitutional Convention.—An agricultural conference was held in Albany May 25 to discuss the question of securing the recognition of agriculture as a broad and fundamental phase of the State's work and the inclusion in the new constitution of a clause defining the scope and work of the State Department of Agriculture. The conference was the result of a call by the State agricultural advisory board, and later broadened by an additional call from the commissioner of agriculture to cover practically all of the agricultural interests of the State. Among the various activities represented were the New York State College of Agriculture at Cornell University, the New York State Experiment Station, the secondary agricultural schools, the state departments of agriculture and education, the grange, the

agricultural press, various agricultural and horticultural societies, the dairy-men's and breeders' associations, and other related bodies.

The conference was addressed by President J. G. Schurman, of Cornell University, and Hon. Seth Low, of the constitutional convention, and by several others. It was pointed out that at the present time over 150 departments, boards, commissions, and similar agencies are authorized to carry on the State's business and the idea was suggested of a plan of reorganization into a few great departments. The conference adopted resolutions advocating the establishment by a provision in the constitution of a State Department of Agriculture, and appointed a committee of ten with Dean Galloway as chairman to consider the scope and functions of such a department. At an adjourned meeting of the conference, held June 21, this committee submitted a series of resolutions, requesting the establishment of the department of agriculture coordinate with the other state departments, "the chief design and duties of which shall be to administer the regulatory laws relating to agriculture and agricultural production, marketing and distribution, lands, forests, fish, and game, and to instruct the people in regard to the meaning and application of such laws." These resolutions were adopted by the conference.

Massachusetts Agricultural Development Committee.—According to a note in *New England Homestead*, an agricultural development committee is being organized with one member each appointed from the Massachusetts College, the state grange, the state boards of agriculture and education, and three members designated by them. This committee is to outline a plan for studying and mapping the agricultural resources of the State and developing agriculture and country life in a comprehensive way, and to recommend a form of organization and work for state-supported agencies necessary to this development, and for correlating the various organizations, both public and private, designed to benefit country life. It is also to index and codify all state laws on the subject.

Agricultural Work in Cyprus.—The buildings of the department of agriculture comprise a main building containing the offices, lecture rooms for the students of the agricultural school, entomological and chemical laboratories, workshops for students learning bee keeping and basket making, and outbuildings used for the experimental distillation of oils, etc.

The department maintains seven large and several smaller gardens throughout the island and a model farm at Athalassa, near Nicosia, which is giving increasing attention to the breeding of animals. It also directs agricultural experiments in different districts; gives instruction in agriculture to teachers during the summer vacations both in the classroom and by means of outdoor demonstrations; and in collaboration with the department of education has established about 50 school gardens which are under its general guidance and observation.

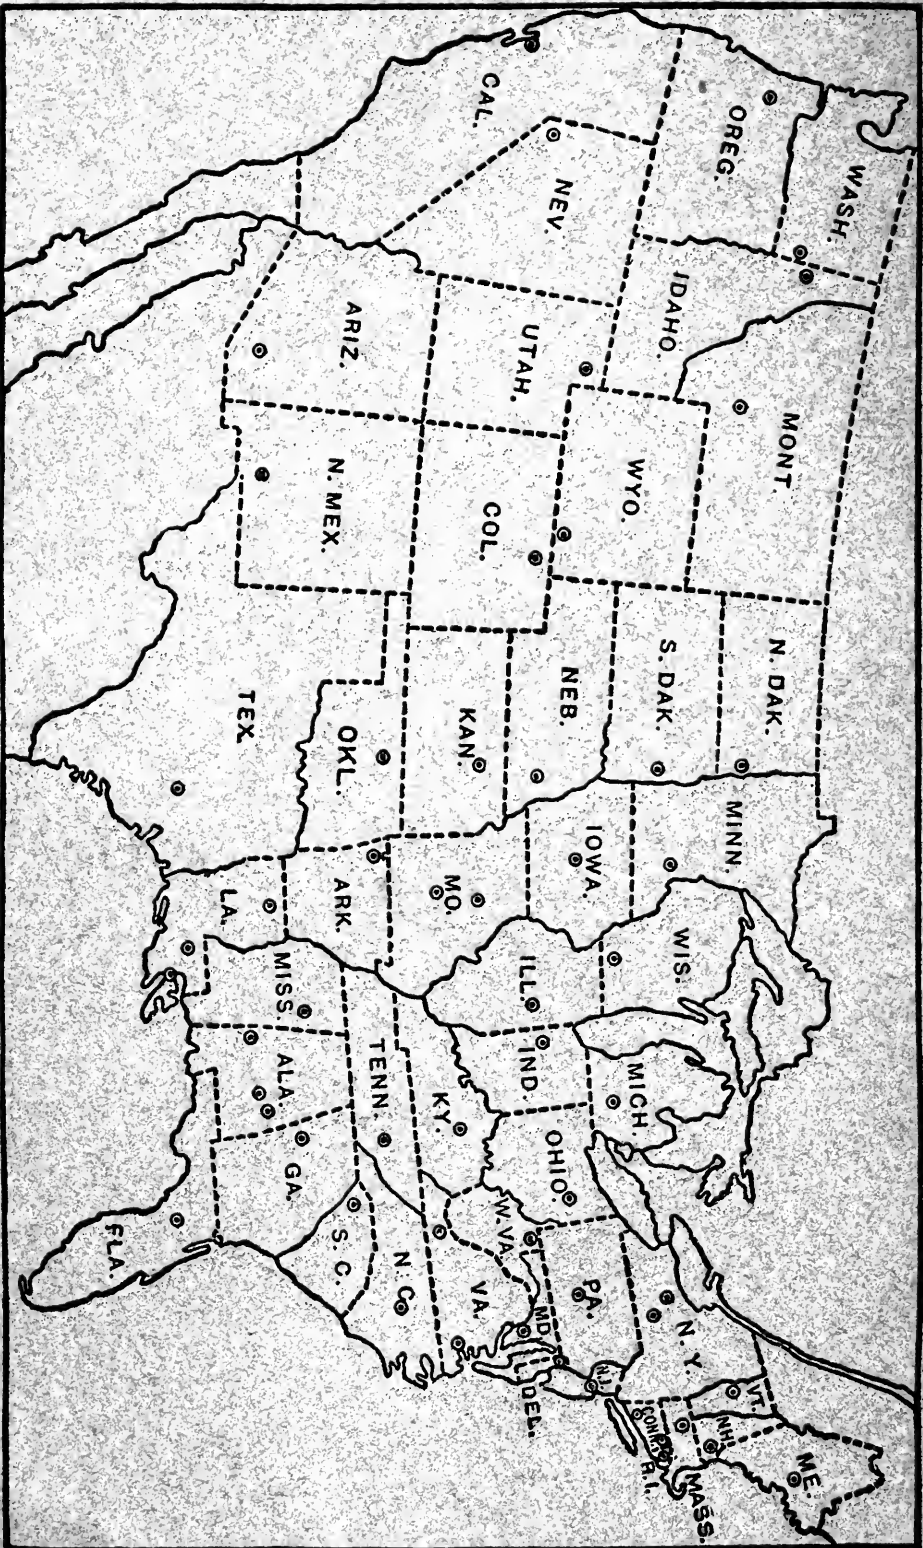

A series of weekly lectures on agricultural subjects is given at the Theological College, Larnaca, and the officers of the department, when traveling in their districts, advise farmers in regard to field and garden operations.

The experimental garden at Nicosia is being reorganized to serve as an experimental garden, a model orchard for practical instruction both to the students of the agricultural school and the public, a nursery garden for raising fruit seedlings for propagation, and a public promenade.

Notes on the production of tropical plants, De Wildeman.....	221
Obligate symbiosis in <i>Calluna vulgaris</i> , Rayner.....	221
<i>Andropogon halepensis</i> and <i>A. sorghum</i> , Piper.....	221
Additional evidence of mutation in <i>E. nothera</i> , Bartlett.....	221
Cultural bud mutations in subterranean portions of <i>Solanum caldasii</i> , Heckel..	222
The effect of salt on the growth of <i>Salicornia</i> , Halket.....	222
The total amino nitrogen in the seedlings of the Alaska pea, Thomspson.....	222
The significance of sugar in tubers of <i>Solanum tuberosum</i> , Butler.....	223

	Page.
Concentration of the nutrient solution and rate of growth of plants, Stiles.....	223
The summer rest of bulbs and herbaceous perennials, Howard.....	223
The rest period in pot-grown woody plants, Howard.....	223
The relative transpiration of white-pine seedlings, Burns.....	224
The visible effects of the Schumann rays on protoplasm, Bowie.....	224
The later researches on anthocyan, Keegan.....	224
Micro-organisms in silage, Mundy.....	224
An improved nonabsorbing porous cup atmometer, Shive.....	224

FIELD CROPS.

Dry farming investigations in western North Dakota, Thysell et al.....	225
Dry farming in Egypt, Alchevski.....	225
[Report on the progress of farm crops investigations].....	225
Growing field root, vegetable, and flower seeds in Canada, Malte and Macoun.....	226
Farm crops, Zavitz.....	226
Work in the nurseries and distribution of plants, Birkinshaw.....	227
[Field experiments], Birt.....	227
[Field experiments], Basu.....	227
Growing forage crops for hogs, Snapp.....	227
Native pasture grasses of the United States, Griffiths et al.....	227
Pasture problems: Response of individual species under manures, Stapledon.....	227
Tanks for determination of water requirements of grasses, von Seelhorst.....	228
Grasses and clovers on the Murrumbidgee irrigation area, McDiarmid.....	228
Experiments on manuring grass at Moorlands Farm, Warwickshire, Parke.....	228
Universal hay tonnage table, Chestnut.....	228
Western hay tonnage table, Chestnut.....	228
Grain inspection in Canada, Magill.....	228
The peas and beans of Burma, Thompstone and Sawyer.....	229
Soy beans and cowpeas, Kiesselbach.....	229
Soil physics and moisture in relation to alfalfa, McNeely and Kable.....	229
Effect of frequent cutting on water requirement of alfalfa, Briggs and Shantz.....	230
Barley in Great Plains area: Relation of cultural methods, Chilcott et al.....	230
Field beans, a profitable West Virginia crop, Cook.....	231
Hardier spineless cactus, Griffiths.....	231
Corn in the Great Plains area: Relation of cultural methods, Chilcott et al.....	231
A new and prolific variety of cotton, Carver.....	232
[Flax growing], Bolley.....	232
Fiber flax, Miles.....	232
Oats in the Great Plains area: Relation of cultural methods, Chilcott et al.....	232
Potato breeding and selection, Stuart.....	233
Report of the Prickly Pear Experimental Station, Dulacca, White.....	233
The prickly-pear problem in Australia, Juritz.....	233
Some observations on Upper Burma paddy (grown under irrigation), Thompstone.....	234
The transplanting of [rice], McGowan.....	234
Notes on the hydrocyanic acid content of sorghum, Willaman and West.....	234
Soy beans, an important West Virginia crop, Cook and Kemp.....	235
Saccharose formation in the sugar beet, Colin.....	235
Sweet potato [experiments], Watts.....	235
The early agricultural history of timothy, Piper and Bort.....	235
A text-book on tobacco, Werner.....	235
Relation between dry matter and winter resistance of winter wheats, Sinz.....	235
Hard wheats winning their way, Carleton.....	235

HORTICULTURE.

[Progress report on horticultural investigations].....	235
Division of horticulture.—Summary of results, 1914, Macoun et al.....	236
The university farm garden, Dacy.....	237
Cabbage, cauliflower, turnip, rape, and other crucifers, Brooks.....	238
How to grow muskmelons, Lloyd.....	238
Arboriculture in Spain, Priego.....	238
Annual report on the Fruit Experiment Station, Shillong, 1914, Holder.....	238
[Final reports of the Royal Commission on the Fruit Industry].....	238
New or noteworthy fruits, III, Hedrick.....	238
Experimental results in young orchards in Pennsylvania, Stewart.....	238
Making old orchards profitable, Greene.....	240

	Page.
Stock influence on vintage quality and other characters of apples, Barker.....	240
The cacao tree in the State of Bahia, Zehntner.....	240
Citrus fertilization experiments in Porto Rico, Kinman.....	241
Drug plants under cultivation, Stockberger.....	241
Experiments in hybridizing Japanese flowers, Jenny.....	242
Dwarf evergreens, Nash.....	242
Lime and sulphur solutions, Stone.....	242

FORESTRY.

The National Forests and the farmer, Graves.....	242
The farm woodlot problem, Smith.....	242
The new Massachusetts forest taxation law, Rane.....	242
Natural reforestation in mountains of northern Idaho, Humphrey and Weaver. [Report of progress on] forestry.....	242
The preservation of structural timber, Weiss.....	243
The deterioration of lumber.—A preliminary study, Pratt.....	243

DISEASES OF PLANTS.

Physiological relations of powdery mildews to their hosts, Reed.....	244
Studies in the genus <i>Phytophthora</i> , Rosenbaum.....	244
The <i>Verticillium</i> wilt problem, Carpenter.....	244
Classification of local rusts, Bennett.....	245
<i>Puccinia graminis</i> and host plants immune to its attack, Stakman.....	245
Grain smut infections and control, Reed.....	245
A bacterial leaf spot disease of celery, Jagger.....	245
Downy mildew of cucumbers, Stone.....	245
The control of onion smut, Stone.....	245
Leaf spot and some fruit rots of peanut, Wolf.....	245
Effect of temperature on the common potato scab organism, Shapovalov.....	245
The use of sulphur for the control of potato scab, Lint.....	246
Seedling diseases of sugar beets and relation to root and crown rots, Edson.....	246
<i>Phoma beta</i> on the leaves of the sugar beet, Pool and McKay.....	246
Blossom-end rot of tomatoes, Brooks.....	247
Resistance to <i>Cladosporium fulvum</i> in tomato varieties, Norton.....	247
Loss from mosaic disease of tomato, Norton.....	247
Orchard experiments in 1914, Cook and Martin.....	247
Hosts of brown rot <i>Sclerotinia</i> , Norton.....	247
Apple fruit spot and quince blotch, Brooks and Black.....	247
Apple leaf spot, Brooks and De Meritt.....	247
Apple rust or cedar rust in West Virginia, Giddings and Berg.....	247
Treatment of apple canker diseases, Whitten.....	248
A nursery disease of the peach, Cook and Schwarze.....	248
A wilt disease of Japanese and hybrid plums, Higgins.....	248
Studies on <i>Plasmopara viticola</i> , Gregory.....	248
Citrus canker, Massey.....	248
A new rust of economic importance on cultivated snapdragon, Peltier and Rees.....	248
A <i>Nectria</i> parasitic on Norway maple, Cook.....	249
Thrombotic disease of maple, Rankin.....	249
A mutation in <i>Phyllosticta</i> , Crabill.....	249
The perfect stage of <i>Phyllosticta parvix</i> , Stewart.....	249
Longevity of pycnospores and ascospores of <i>E. parasitica</i> , Heald and Studhalter.....	249
An unreported fungus on the oak, Schwarze.....	250
Notes on soil disinfection, Hartley.....	250
Nematodes and their relationships, Cobb.....	250

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Field mice as farm and orchard pests, Lantz.....	250
Our shore birds and their future, Cooke.....	250
Eleven important wild duck foods, McAtee.....	251
Mortality among waterfowl around Great Salt Lake, Utah, Wetmore.....	251
Effect of temperature and moisture on the rate of insect metabolism, Headlee.....	252
On the valuation of lime-sulphur as an insecticide, Tartar.....	252
Insecticide formulas, Woodworth.....	252
Twenty-ninth report of the State entomologist, 1913, Felt.....	252

	Page.
Additional notes on Porto Rican sugar-cane insects, Jones.....	253
The California pear thrips in Maryland, Scott.....	253
Status of spraying for plant lice in apple orchards, Parrott and Hodgkiss.....	253
Controlling plant lice in apple orchards, Hall.....	253
Four aphids injurious to the apple, Pickett.....	253
Control of the San José scale in Missouri, Haseman.....	253
Notes on Coccidæ found in Peru, Rust.....	254
Report on the gipsy moth work in New England, Burgess.....	254
Wilt or gipsy moth caterpillars, Glaser.....	254
The squash-vine borer, Chittenden.....	255
The verbena bud moth, Fink.....	255
The serpentine leaf-miner on cotton, McGregor.....	255
List of zoophagous Itonididæ, Felt.....	255
<i>Arthrocnodax constricta</i> n. sp., Felt.....	255
Losses to rural industries through mosquito bites that convey malaria, Van Dine..	255
Introduction of tachinid parasite of sugar cane weevil borer in Hawaii, Swezey..	256
On the original habitat of <i>Stomoxys calcitrans</i> , Muir.....	256
Susceptibility of <i>Pollenia rudis</i> to nicotine, Parrott.....	256
The probable best method of rearing certain scarabæid larvæ, Girault.....	256
<i>Agrius politus</i> infesting roses, Weiss.....	256
A new pest of cane in Fiji (<i>Sphenophorus nebulosus</i>), Illingworth.....	256
Some coccinellid statistics, Ewing.....	256
Notes on the rice water weevil (<i>Lissorhoptrus simplex</i>), Webb.....	257
Effect of temperature on oviposition of <i>Phytonomus posticus</i> , Parks.....	257
Relation of Arizona wild cotton weevil to cotton in arid West, Coad.....	257
Notes on the life history of <i>Prospaltella permiciosi</i> , Tower.....	257
Capture of living insects by cornfield ant (<i>Lasius niger americanus</i>), Flint.....	258
Description of a new sawfly injurious to strawberries, Rohwer.....	258
The economic status of the fungus diseases of insects, Glaser.....	258
Harvest mites, or "chiggers," Chittenden.....	258

FOODS—HUMAN NUTRITION.

Air, water, and food from a sanitary standpoint, Woodman and Norton.....	258
Progress in food chemistry, Beckurts, Frerichs, and Beck.....	258
Preservation of meat, Gurini.....	259
Pork and pork fat and their use in the household, Herter and Wilsdorf.....	259
Composition of corn meal manufactured by different processes, Winton et al..	259
The use of rice flour in bread making, Novelli.....	260
Bitter and sweet cassava—hydrocyanic acid contents, Collins.....	260
Ash content of canned vegetables, with special reference to peas, Morgan.....	260
[Food and drug inspection].....	260
Ohio food and drug laws.....	261
Meat and food inspectors' examinations, Billing and Walker.....	261
Selection of household equipment, Atwater.....	261
The school lunch service, Brown.....	261
Memorandum on providing meals for children in public schools, Selby-Bigge..	261
Prevention of beri-beri by modifications in the diet, Chamberlain.....	261
The metabolic relationship of the proteins of glucose, Janney.....	261
The influence of the plane of protein intake on growth, McCollum and Davis.....	262
Comparative nutritive value of certain proteins in growth, Osborne et al.....	262
The influence of natural fats upon growth, Osborne et al.....	262
Purin metabolism of man.—III, Decomposition of purin compounds, Sivéu.....	263
Metabolism of vegetarians as compared with nonvegetarians, Benedict and Roth	263
The metabolism of athletes, Benedict and Smith.....	263
The basal metabolism of normal men and women, Benedict and Emmes.....	264
Factors affecting basal metabolism, Benedict.....	264
A respiration apparatus for small animals, Benedict.....	265
Corrections in bomb calorimetry, Huntly.....	265

ANIMAL PRODUCTION.

Animal husbandry.....	265
Some factors affecting fetal development, Evvard.....	266
On the variation in the growth of mammalian tissue in vitro, Walton.....	267
The English rabbit and Mendelian unit-character constancy, Castle and Hadley..	267
Breeding of farm animals, Harper.....	267
The jack bean (<i>Canavalia ensiformis</i>), Barnstein.....	267

	Page.
Beet residues for farm stock, Lindsey.....	267
Ensiling potatoes with a lactic acid culture, Air and Mayr.....	268
Factors affecting range management in New Mexico, Wooton.....	268
Meat production in Argentina and effect on United States, Melvin and Rommel.....	268
Meat production in Australia and New Zealand, Joss.....	268
Raising the dairy calf, Woodward.....	268
Feeding sour milk to young calves, Woodward.....	269
Calif-rearing experiments in Hungary, Kerekes.....	269
Notes on degeneration in the teeth of oxen and sheep, Jackson.....	270
The woolgrower and the wool trade, Marshall and Heller.....	270
Suggestions from Australasia to American sheep raisers, Marshall.....	270
Breaking and training colts, Stambaugh.....	271
Average and frequency curves, Potts.....	271
Sex-linked inheritance in poultry, Lefevre.....	271
Changes in the secondary sexual characters of Gallinæ, Pézard.....	272
Sexual differentiation of pigeon's eggs.....	272
The Campines, edited by Platt.....	273
The White Leghorn, Hadley.....	273
Chickens: Milk feeding and influence on growth and mortality, Rettger et al.....	273
The poultry industry in New York State.....	273
The egg and poultry demonstration-car work, Pennington et al.....	273
Edible snails, Rust.....	274

DAIRY FARMING—DAIRYING.

Dairy husbandry.....	274
Development and present state of dairying in Sweden, Haglund.....	274
A study of three thousand advanced register records.....	275
Champion cows of each breed.....	275
Rations for dairy stock, Lindsey.....	275
Feeding dairy cows cassava meal, Lucas.....	275
Influence of grazing and of dry-stall feeding on milk, Brunovsky.....	275
Relation of quality of proteins to milk production, Hart, Humphrey et al.....	275
The cost of milk production, Hopper and Robertson.....	276
Cost of food in production of milk in Kent and Surrey.....	276
Milk and cream.....	277
Condensed milk, McGill.....	277
Evaporated milk, McGill.....	277
Devonshire "clotted" cream, Sadler.....	277
Applications of bacteriology to the dairy industry, Fascetti.....	277
Micro-organisms and Brindza cheese, Gratz and Vas.....	277
Production of a nutritive beverage from skim milk, Eichloff.....	278

VETERINARY MEDICINE.

[Report of the veterinary department], Connaway et al.....	278
Studies from the Rockefeller Institute for Medical Research.....	279
Some diseases discussed in the light of the vitamin theory, Reinhardt.....	279
Some important animal parasites affecting Ohio live stock, Mote.....	279
Revised check list of parasites of domesticated animals in India, Gaiger.....	279
Abderhalden's protective ferments, Brahm.....	279
The nature of the meiotagmin reaction with malignant tumors, Izar.....	280
Abderhalden's reaction and its relation to antithrombin in blood, De Waele.....	280
Preparation and standardization of vaccines, antitoxins, and serum, Fitch.....	280
The pharmacological action of some serum preservatives, Voegtlin.....	280
Studies on complement action, Browning and Mackie.....	280
Investigations of the nature of anaplasms, Dias and Aragão.....	281
Status of bacilli from fish meal which give a positive Ascoli reaction, Zingle.....	281
Investigations of foot-and-mouth disease, Loeffler.....	281
Foot-and-mouth disease, its nature, cause, and treatment, compiled by Smith.....	281
An improved method for the detection of mangeacar, Sheather.....	281
The relapse in piroplasmosis, Carpano.....	281
Piroplasmosis of Rhodesian sheep, as observed by Bevan, Wenyon.....	282
Laboratory studies on tetanus, Francis.....	282
Antigenic properties of East African trypanosomes, Schilling.....	282
Effect of daylight and drying on tubercle bacilli, Findlay and Martin.....	282
Histological studies on serous tuberculosis of bovines, Joest and Marjanen.....	282

	Page.
The significance of fowl tuberculosis for the pig, Christiansen.....	282
Organ tuberculosis in pigs caused by avian type of bacillus, Christiansen.....	283
The iodine content of tuberculous tissues, Lewis and Krauss.....	283
Besredka's antigen in tuberculosis diagnosis, Bronfenbrenner and Rockman..	283
Value of a new skin test for diagnosis of tuberculosis, Bronfenbrenner.....	283
Tuberculin in tuberculous and nontuberculous organisms, Ruppel and Joseph..	283
Tuberculosis protective vaccination with antiphymatol, Krautstrunk.....	284
The tuberculosis problem in rural communities, Knopf.....	284
Contribution to the serodiagnosis of infectious abortion in bovines, Kloubok..	284
A note on <i>Syngamus laryngeus</i> from cattle in the Philippine Islands, Hall.....	284
Hog cholera and paratyphoid of pigs, Miessner.....	285
What is hog cholera? Hutyra.....	285
Remarks on the hog cholera question, Joest.....	285
Immunization against erysipelas in hogs, Burgkart.....	285
Filariasis in native horses, Wirth.....	285
The use of neosalvarsan, Furi.....	286

RURAL ENGINEERING.

Irrigation and soil conditions in Sierra Nevada foothills, Robertson and Nelson..	286
[Irrigation experiments on the Koppenhof experimental field], Richter.....	286
[Irrigation experiments on the Bromberg experimental field], Richter.....	286
The water economy of the soil, Richter.....	287
Studies in water supply, Houston.....	287
River discharge, Hoyt and Grover.....	287
Surface water supply of the Yukon-Tanana region, Ellsworth and Davenport..	287
Report on the surface water supply of New Mexico, 1913, French.....	288
The inverted weir, Rettger.....	288
Report upon the Cypress Creek drainage district, Arkansas, McCrory et al.....	288
Excavating plant for heavy drainage work in Arkansas.....	288
The economy of farm drainage, Marsden.....	288
Clean water and how to get it on the farm, Trullinger.....	289
Annual report on highway improvement Ontario, 1913, McLean.....	289
Traffic factors, Eastwood.....	289
Relation of road maintenance to traffic, Sohler.....	290
Notes on the selection of pavements for heavy-traffic roads, Shirley.....	290
State management of public roads, its development and trend, Pennybacker..	290
Standard concrete culverts recommended by Michigan Highway Department..	291
Making fences, walls, and hedges, Butterfield.....	291
Mechanical cultivation in Belgium, Diftloth.....	291
The effect of varying the percentage of water in concrete.....	292

RURAL ECONOMICS.

The organization of a rural community, Carver.....	292
Concerning the organization of agricultural enterprises.....	292
Information on rural economy and administrative organization of agriculture....	292
[Winter agricultural work], Hofmeister.....	292
The cost of production on Missouri farms, Johnson and Foard.....	292
Market distribution.....	293
Retail public markets, Branch.....	294
Farmers' market bulletin.....	294
Cooperative marketing, and financing of marketing associations, Bassett et al..	294
Departmental committee on agricultural credit in Ireland.....	294
[Transportation of agricultural products in France].....	294
Movement from city and town to farms, Holmes.....	294
The American farm woman as she sees herself, Mitchell.....	294
Conference on rural life and work.....	295
The organization of the agricultural statistical service in various countries....	295
Monthly crop report.....	295
Annual international report on agricultural statistics for 1911-12.....	295
[Agricultural statistics].....	295
[Agriculture in Argentina].....	295
Agricultural statistics of British India.....	295
[Agricultural population of British India].....	295
Live stock in Germany.....	296

AGRICULTURAL EDUCATION.

	Page.
[Agricultural] instruction.....	296
[Agricultural education under the direction of the chamber of agriculture]....	296
[School gardening and nature study].....	296
The growth and influence of the nature-study idea, Comstock.....	296
Boys' and girls' contest clubs, Bailey.....	296
Elementary agriculture, Nolan.....	297
Outlines in agriculture, domestic science, and manual training.....	297
Laboratory exercises in principles of agriculture, Hopt and Spafford.....	297
Hotbeds: Their construction and use, Minear.....	297
Peppers, Powell, Creswell, and Tracy.....	297
Identification of potato varieties, Fitch.....	297
Studies of trees, Levison.....	297
Farm forestry, Akerman.....	298
A manual of exercises in forest mensuration, Winkenwerder and Clark.....	298
Modern methods of testing milk and milk products, Van Slyke.....	298
The nature-study course of the elementary school, Caldwell.....	298
The nature-study course of the school of observation and practice, Schively....	298
Nature study, Churchill.....	298
Nature study and agriculture.....	298
Nature study at the Van Vlissingen School, Brennan.....	298
Home work for winter months for canning club girls of Tennessee, Turner....	298
Homemakers' clubs for negro girls, Sibley.....	299

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1914.....	299
Report on the agricultural experiment stations, 1913.....	299
Twenty-sixth Annual Report of Maryland Station, 1913.....	299
Work and progress of the station, 1914.....	299
Monthly bulletin of the Western Washington Substation.....	299
[Index to Wyoming Station publications, 1907-1914], Anderson.....	299

LIST OF EXPERIMENT STATION AND DEPARTMENT PUBLICATIONS REVIEWED.

<i>Stations in the United States.</i>	Page.	<i>Statistics in the United States—Con.</i>	Page.
Alabama Tuskegee Station:		New York State Station:	
Bul. 26, 1915.....	232	Bul. 400, popular ed., Mar., 1915.....	220
California Station:		Bul. 402, Apr., 1915.....	253
Bul. 252, May, 1915.....	243	Bul. 403, Apr., 1915.....	238
Bul. 253, May, 1915.....	286	Tech. Bul. 41, Apr., 1915.....	201
Circ. 128, Apr., 1915.....	252	North Carolina Station:	
Connecticut Storrs Station:		Farmers' Market Bul., vol. 2, No. 2, Apr., 1915.....	294
Bul. 80, Apr., 1915.....	273	North Dakota Station:	
Illinois Station:		Bul. 110, Feb., 1915.....	225
Circ. 139 (second ed., rev.), Feb., 1915.....	238	Circ. 6, Apr., 1915.....	232
Circ. 179, Apr., 1915.....	253	Ohio Station:	
Iowa Station:		Bul. 280, Dec., 1914.....	
Circ. 20, Mar., 1915.....	240	Pennsylvania Station:	
Maine Station:		Bul. 134, Apr., 1915.....	238
Off. Insp. 67, Feb., 1915.....	277	Porto Rico Station:	
Maryland Station:		Bul. 18, May 14, 1915.....	241
Twenty-sixth An. Rpt., 1913..	299	Washington Station:	
Massachusetts Station:		West. Wash. Sta. Mo. Bul., vol. 3—	
Circ. 48, Dec., 1914.....	267	No. 2, May, 1915.....	299
Circ. 49, Feb., 1915.....	238	No. 3, June, 1915.....	299
Circ. 50, Mar., 1915.....	275	West Virginia Station:	
Circ. 51, Mar., 1915.....	245	Circ. 15, Mar., 1915.....	247
Circ. 52, Mar., 1915.....	245	Circ. 16, Apr., 1915.....	220
Circ. 53, Apr., 1915.....	242	Circ. 17, Apr., 1915.....	237
Circ. 54, Apr., 1915.....	218	Circ. 18, Apr., 1915.....	231
Missouri Station:		Circ. 19, Apr., 1915.....	227
Bul. 125, Feb., 1915.....	292	Circ. 20, Apr., 1915.....	235
Bul. 126, Mar., 1915.....	212	Wisconsin Station:	
Bul. 127, Mar., 1915.....	213	Bul. 249, Feb., 1915.....	206
Bul. 128, Apr., 1915.....	213	Wyoming Station:	
Bul. 129, Apr., 1915.....	214	Index Bul. E, Mar., 1915.....	299
Bul. 130, Apr., 1915.....	214		
Bul. 131 (An. Rpt. 1914), Apr. 1915 . . . 215, 224, 225, 235, 242, 244, 245, 248, 265, 271, 274, 278, 299		<i>U. S. Department of Agriculture.</i>	
Bul. 132, Apr., 1915.....	253	Jour. Agr. Research, vol. 4, No. 2, May, 1915.....	217, 234, 245, 246, 254
Research Bul. 15, Apr., 1915...	223	Bul. 195, Potato Breeding and Selection, W. Stuart.....	233
Research Bul. 16, Apr., 1915...	223	Bul. 196, Methods Followed in the Commercial Canning of Foods, A. W. Bitting.....	210
Nebraska Station:		Bul. 198, Report Upon the Cypress Creek Drainage District, Desha and Chicot Counties, Ark., S. H. McCrory et al.....	288
Bul. 149, Apr. 5, 1915.....	268	Bul. 201, Native Pasture Grasses of the United States, D. Griffiths, G. L. Bidwell, and C. E. Goodrich.....	227
Bul. 150, Apr. 6, 1915.....	229		
New Hampshire Station:			
Sci. Contrib. 5, Apr., 1912....	247		
Sci. Contrib. 6, Oct., 1912....	247		
Sci. Contrib. 7, Apr., 1913....	223		
Sci. Contrib. 8, Oct., 1914....	247		
New Mexico Station:			
Bul. 93, Mar., 1915.....	229		
New York Cornell Station:			
Bul. 357, Mar., 1915.....	276		

<i>U. S. Department of Agriculture—Con.</i>		Page.	<i>U. S. Department of Agriculture—Con.</i>		Page.
Bul. 204, Report on the Gipsy Moth Work in New England, A. F. Burgess.....		254	Office of Experiment Stations: Rpt. Work and Expenditures of Agricultural Experiment Stations, 1913.....		299
Bul. 205, Eleven Important Wild-Duck Foods, W. L. McAtee....		251	Scientific Contributions: ^a Additional Evidence of Mutation in <i>Cenothera</i> , H. H. Bartlett.....		221
Bul. 206, The Woolgrower and the Wool Trade, F. R. Marshall and L. L. Heller.....		270	The Availability of Nitrogen in Kelp, J. A. Cullen.....		206
Bul. 211, Factors Affecting Range Management in New Mexico, E. O. Wootton.....		268	The Economic Status of the Fungus Diseases of Insects, R. W. Glaser.....		258
Bul. 215, Composition of Corn (Maize) Meal Manufactured by Different Processes and the Influence of Composition on the Keeping Qualities, A. L. Winton et al.....		259	Hardier Spineless Cactus, D. Griffiths.....		231
Bul. 217, Mortality Among Waterfowl Around Great Salt Lake, Utah, A. Wetmore.....		251	A Note on <i>Syngamus laryngeus</i> from Cattle in the Philippine Islands, M. C. Hall....		284

ABSTRACT NUMBER.

No. 3.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL CHEMISTRY—AGROTECHNY.

International catalogue of scientific literature. D—Chemistry (*Internat. Cat. Sci. Lit.*, 10 (1913), pp. VIII+934; 11 (1914), pp. VIII+966).—The tenth and eleventh annual issues of this catalogue (E. S. R., 27, p. 718), which contain subject and author indexes for material received between October, 1910, and October, 1911, and October, 1911, and October, 1912, respectively.

Fibrin, A. W. BOSWORTH (*New York State Sta. Tech. Bul.* 41 (1915), pp. 3-6; *Jour. Biol. Chem.*, 20 (1915), No. 1, pp. 91-94).—While working with blood certain observations seemed to indicate that fibrin might possess some chemical properties quite similar to those of casein reported by L. L. Van Slyke and A. W. Bosworth (E. S. R., 29, p. 9).

It was found that "fibrin can combine with both bases and acids to form definite compounds. Fibrin combines with four equivalents of base to form a compound which is neutral to phenolphthalein. Fibrin combines with bases to form a series of three acid salts which contain one, two, and three equivalents of base, respectively. All the combinations of fibrin with sodium, potassium, and ammonium are soluble. The calcium fibrinates containing three and four equivalents of calcium are soluble, the calcium fibrinates containing one and two equivalents of calcium being insoluble. Fibrin combined with one equivalent of acid is insoluble, and combined with more than one equivalent of acid is soluble. Pure fibrin, unlike casein, is not strong enough as an acid to decompose calcium carbonate. The molecular weight of fibrin is about 6,666. Carbon dioxide precipitates fibrin from a solution of calcium fibrinate, but not from a solution of sodium, potassium, or ammonium fibrinate."

The nature of the free amino groups in proteins, D. D. VAN SLYKE and F. J. BIRCHARD (*Jour. Biol. Chem.*, 16 (1914), No. 4, pp. 539-547).—"In all the native proteins investigated the amount of free amino nitrogen is equal to one-half the lysin nitrogen, no deviation exceeding the limit of experimental error of the amino and lysin determinations being found in any case, with the possible exception of gliadin, in which the difference is 0.7 per cent. The period required for complete reaction of the proteins with nitrous acid (thirty minutes) is longer than that required by the α -amino groups (three to four minutes), but corresponds to that found for lysin, with a w -amino group free. The facts support the following conclusions:

"(1) One of the two amino groups of lysin, the w -group, exists free in the protein molecule. (2) This group represents, within at most a fraction of a

per cent of the protein nitrogen, the entire amount of free NH_2 determinable in the native proteins by the nitrous acid method. The α -amino groups, which constitute the remaining and greater part of the free amino nitrogen found after complete hydrolysis, are, in the intact protein molecule, practically all condensed into peptid linkings. (3) With the primary albumoses the relations are different. The free NH_2 in hetero- and protoalbumose exceeds half the lysin nitrogen, by 3 and 4.2 per cent, respectively, of the total protein nitrogen, indicating that an appreciable portion of the α -amino groups is uncovered in even the primary digestion products."

Newer investigations on the protein metabolism of yeast and mold fungi, F. EHRLICH (*Ztschr. Angew. Chem.*, 27 (1914), No. 8, Aufsatzteil, pp. 48-52).—A detailed and critical discussion of the subject, especially in the light of the author's findings.

The constituents of the flowers of *Anthemis nobilis*, F. B. POWER and H. BROWNING, JR. (*Jour. Chem. Soc. [London]*, 105 (1914), No. 621, pp. 1829-1845).—The flower heads of the composite plant, *A. nobilis*, known as the Roman or English camomile, are used to a considerable extent as a medicine and are recognized by the United States, British, and other national pharmacopœias. The material used in this investigation was collected from plants grown in Belgium.

"Apart from the essential oil yielded by distillation with steam, the flowers have been found to contain the following definite compounds: (1) 3:4 dihydroxycinnamic acid; (2) apigenin, $\text{C}_{15}\text{H}_{10}\text{O}_5$; (3) a glucosid of apigenin, $\text{C}_{21}\text{H}_{20}\text{O}_{10}\cdot\text{H}_2\text{O}$ (melting point 178 to 180°), which yields a hexa-acetyl derivative, $\text{C}_{33}\text{H}_{22}\text{O}_{16}\cdot 4\text{H}_2\text{O}$, melting at 144 to 146°; (4) cholin, $\text{C}_5\text{H}_{15}\text{O}_2\text{N}$; (5) *i*-inositol, $\text{C}_6\text{H}_{12}(\text{OH})_6$; (6) triacontane, $\text{C}_{30}\text{H}_{62}$; (7) taraxasterol, $\text{C}_{29}\text{H}_{47}\cdot\text{OH}$ (melting point 217 to 219°); (8) a phytosterolin (melting point 280 to 283°), consisting chiefly of sistosterol-*d*-glucosid, $\text{C}_{27}\text{H}_{46}\text{O}_6$; (9) a mixture of fatty acids, consisting of cerotic, stearic, palmitic, oleic, and linoleic acids. The flowers contained, furthermore, a considerable quantity of sugar, which yielded *d*-phenylglucosazone (melting point 208 to 210°). The amount of fatty and resinous material, from which some of the above-mentioned substances were obtained, was equivalent to about 7.4 per cent of the weight of flowers employed.

"The so-called 'anthemic acid' of previous investigators was evidently a very indefinite product, while the 'anthesterol' of Klobb was doubtless a mixture, consisting chiefly of the compound which has been designated by the authors as taraxasterol.

"The bitter taste of camomile flowers appears to be due to dark-colored, amorphous material, and not to any well-defined constituent. It was found, for example, that the portion of the alcoholic extract which is soluble in water yielded, when extracted successively with ether and amyl alcohol, viscous products which possessed an intensely bitter taste."

Investigations on oil of black sage, C. E. BURKE and C. C. SCALIONE (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 10, pp. 804-806, figs. 2).—The oil of black sage (*Ramona stachyoides*), a plant which grows abundantly in California, was studied, first with the idea of determining the yields of camphor and cineol at slightly different seasons of the year, and secondly to determine definitely the other constituents and whether or not any of the constituents were present in sufficient amounts to be commercially important.

Analyses of the oil of black sage showed pinene 6 per cent, cineol 30, dipentene, terpinene, etc., 25, thujone 8, camphor 25, and resinous material 5 per cent. The results also give a good indication as to the variation of the constituents of the oil with the season.

See also a previous note by Rabak (*E. S. R.*, 26, p. 612).

Oils of the Coniferæ.—II, The leaf and twig, and bark oils of white fir, A. W. SCHORGER (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 10, pp. 809, 810).—This continues previous work (E. S. R., 33, p. 18).

The approximate composition of the oils of white fir (*Abies concolor*) is given as follows: *l*-*a*-pinene 12 in leaf and twig oil and 9 per cent in bark oil; *l*-B-pinene 42 and 60 per cent; ester as bornyl acetate 6.5 and 2.5 per cent; free borneol 9.5 and 4.5 per cent; and "green oil" 3 and 5 per cent, respectively. The leaf and twig oil fraction boiling at 170 to 180° C. showed 15 per cent *l*-phellandrene, while the bark oil fraction at the same temperature showed dipentene 12 to 13 per cent. Furfural was present only in traces in the leaf and twig and in the bark oils, and *l*-camphene was noted only in the leaf and twig oil. The material unaccounted for in the leaf and twig oil was 4 per cent, and in the bark oil 7 per cent.

Milk—its milk sugar, conductivity, and depression of freezing point, LILIAS C. JACKSON and A. C. H. ROTHERA (*Biochem. Jour.*, 8 (1914), No. 1, pp. 1-27).—In this paper the results of measurements of the electrical conductivity, percentage of milk sugar, and depression of the freezing point are reported as a basis for drawing certain physiological deductions and interpretations rather than as a means for the identification and characterization of different milks.

"In milks secreted from different quarters of the cow's udder and from the right and left breasts in women the electrical conductivity and percentage of milk sugar show a strict reciprocity, provided that the secretion of the milk samples corresponds to the same period. In this case the milk samples are secreted against the osmotic pressure of the blood with its variation over that period. They will all have the same osmotic pressure, and if in one sample the sugar is higher than in another then the electrical conductivity will be lower. The reciprocity of milk-sugar content and electrical conductivity is well seen in the milks from a pathological gland which is slowly recovering and becoming normal. In a comparison of the milks of different species of animals the reciprocity between milk sugar and electrical conductivity is evident.

"It is shown that the milk secreted under the stimulus of removal (milking or natural suckling) differs in character from that secreted previously. The contention is that the condition of the blood has not kept absolutely constant and that the reflex milk is secreted against a slightly different blood from that against which the previously formed milk was secreted.

"Morning and evening samples of cows' milk have been compared. The evening milk generally has the higher conductivity, but exceptions exist.

"The exact effect of the proteins of cows' milk in diminishing the electrical conductivity has been estimated, the value found being a diminution of 2.76 per cent of the conductivity for every 1 per cent of protein in the milk. The dialysis experiments employed for determining this effect showed no difference between raw fresh milk and the same boiled for one hour. Also, there was no evidence that boiling has any effect on soluble calcium salts in a state of ionization.

"The effect of climatic changes upon a Holstein herd of cows has been studied. The generalization holds that hot, dry weather increases the electrical conductivity of the milk, whilst wet or cold weather diminishes it. The climatic conditions affect the cows and so indirectly their milk."

On the phosphorus content of starch, A. W. THOMAS (*Biochem. Bul.*, 3 (1914), Nos. 11-12, pp. 403-406).—Positive experiments confirm the conclusions of Ford^a and Fouard^b that it is impossible to free starch entirely of phosphorus.

^a *Jour. Soc. Chem. Indus.*, 23 (1904), No. 8, pp. 414-422.

^b *Compt. Rend. Acad. Sci. [Paris]*, 144 (1907), No. 9, pp. 501-503.

Gravimetric estimation of nitrites, N. BUSVOLD (*Chem. Ztg.*, 38 (1914), No 3, p. 28).—Finding the methods of Lunge, Gerlinger, and Fischer unsatisfactory, one based on the reaction of nitrous acid with bromic acid was studied, as follows: From 1.4 to 1.5 gm. of silver bromate is dissolved in a 750-cc. Erlenmeyer flask in 100 cc. of water and 110 cc. of twice-normal acetic acid solution is added and heated at 80° C. until solution takes place. Then from a dropping funnel provided with a burette tip, 200 cc. of nitrite solution containing 1 gm. of sodium nitrite is allowed to flow dropwise, amid shaking, into the flask until a faint green-colored precipitate of silver bromid is produced. After the funnel has been rinsed out three times with water 30 cc. of sulphuric acid, 1:4, at 85° is added, heated until the fluid becomes clear and the precipitate a light yellow, filtered through a Gooch crucible, and washed with 1 liter of boiling water. The silver bromid is dried at 130° and weighed.

Parallel analyses rarely differed over +0.001, which corresponds to an error of 0.1 per cent, whereas with the Lunge permanganate method it was difficult to get a greater degree of accuracy than 0.3 per cent. Theoretically, above 0.907 gm. of silver bromid corresponds to 1 gm. of sodium nitrite, and an equivalent of 0.8936 gm. of silver bromid was found, which equals 98.5 per cent of sodium nitrite. The permanganate method gave 98.3 per cent.

Observations on the separation and determination of phosphoric acid as ammonium-magnesium phosphate, H. LESCOEUR (*Bul. Soc. Ind. Nord. France*, 42 (1914), pp. 93-97; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 59, *Referatenteil*, p. 459).—The first part of this paper deals with the separation of phosphoric acid as ammonium magnesium phosphate. Attention is called to Varington's method in which the precipitation of calcium, iron, and aluminum phosphates with the magnesium phosphate is prevented by the addition of citric acid. The process as conducted by Joulie is described.

The second portion of the paper, which deals with the weighing of phosphoric acid as ammonium magnesium phosphate, emphasizes the fact that the phosphate precipitates often contain an excess of magnesium. The quantity of magnesium chlorid solution used in the precipitation is in direct proportion to the magnesium content of the precipitate. If, however, the precipitate is dissolved in hydrochloric acid and reprecipitated with ammonia, the pure substance is obtained.

The chemical analyses of soils, A. MITSCHERLICH (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 327-335).—A discussion of existing chemical methods of soil analyses.

The continuous extraction methods are given the preference, because they employ the same strength of acid throughout the entire procedure and have no interference from salts which have previously gone into solution. The author's carbonic-acid-extraction method is discussed in this connection. Before an international method is accepted it is held that we must be sure that it rests on a plant physiological basis, and the results obtained by it must bear some relation to crop yield. The author's quantitative formulation of the law of minimum is proposed as a basis for such a method. It is said that most of the methods in use for determining the permeability of soils by water do not give duplicate results.

Contribution to the complete chemical analysis of soils, A. A. J. VON SIGMOND (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 336-362).—It is stated that extraction of soil with boiling concentrated hydrochloric acid for two hours, or with sulphuric acid, will not serve as a measure for determining weathered soil constituents (weathering complexes, weathering silicates, soil zeolites, or zeolitic soil constituents). Sandy grains of soil from 2 to 0.02 mm. in size

were appreciably attacked when boiling in concentrated hydrochloric acid (specific gravity 1.115) for one hour.

Comparisons were also made of the methods usually employed for dissolving soil constituents, including the Hilgard official, boiling for one hour with hydrochloric acid (specific gravity 1.115), and the Russian, with 10 per cent hydrochloric acid (Gedroits) methods. The greatest solubility of soil constituents was obtained with Hilgard's method and the least by the Russian method. The Hilgard method not only showed the highest potassium oxid, aluminum oxid, and silicic oxid content, but also the largest amount of magnesium oxid, ferric oxid, and sulphuric acid. The official method was in some respects second to Hilgard's method. Biotite, chlorite, calcite, apatite, corundolite, magnetite, and augite when boiled with hydrochloric acid (1.115 specific gravity) for one hour were dissolved, but not microcline, orthoclase, plagioclase, muscovite, tourmaline, amphibole, epidote, hypersthene, staurolite, cyanite, rutile, zircon, ilmenite, and granatite. Treatment with a 10 per cent solution of hydrochloric acid for 10 hours in the water bath dissolved all the minerals soluble in hydrochloric acid of a specific gravity of 1.115, and had also some effect on microcline. Treatment with hydrochloric acid of a specific gravity of 1.115 for 10 hours dissolved all minerals soluble in the same strength of hydrochloric acid in the one-hour period of boiling and had some effect on microcline, plagioclase, muscovite, and amphibole. By treating with hydrochloric acid of a specific gravity of 1.115 according to Hilgard's method for 120 hours in the water bath orthoclase, plagioclase, and the substances soluble in the same strength of hydrochloric acid by boiling for one hour were dissolved, and microcline, muscovite, and amphibole were affected. By the 10-hour treatment and the 120-hour treatment granatite was increased, and by the 120-hour treatment with hydrochloric acid staurolite was increased. Crude clay removed from a soil by means of a centrifuge when subjected to hydrochloric acid (specific gravity 1.115) for 1 and 120 hours, respectively, showed that the greatest solution of the monoxids took place by the 120-hour exposure. An anomaly was noted in the case of soluble silicic acid, however, because less was found after the 120-hour exposure than after the 1-hour treatment.

The characterization of soils on the basis of the chemical analysis is discussed.

Report on the work of the International Commission for chemical soil analysis, A. A. J. VON 'SIGMOND (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 271-279).—A compilation of the most important determinations to be made for judging soils. The references to the literature are given.

The fundamental questions in preparing soil solutions for chemical analysis, A. A. J. VON 'SIGMOND (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 279-296).—For purposes of completeness these data on methods were submitted with the above report.

Contribution to methods of soil analyses, R. ALBERT and O. BOGS (*Internat. Mitt. Bodenk.*, 4 (1914), No. 2-3, pp. 181-198).—A report on attempts to simplify existing methods for humus, moisture, and specific gravity of soil.

It was found that the Knop method for humus does not show a sharp end point and the glass parts of the apparatus are often attacked and must be frequently replaced. If the sample of soil is rubbed up gently in a porcelain mortar the method will yield very satisfactory results. The amount of carbon dioxid produced multiplied by 0.471 equals the humus content of the soil. The Wahnschaffe suggestion to keep soil in contact with sulphuric acid before the regular oxidation process is deemed a disadvantage rather than an advantage.

Figures obtained by the elementary analysis method according to Dennstedt^a were generally higher than those given by the Knop method. Only in the case

^a Anleitung zur vereinfachten Elementaranalyse, Hamburg, 1906, 2. ed., pp. 99, figs. 20.

of lime soils were the results comparable. Evidently it is advisable to determine the calcium content of each soil before making a humus determination by this method. The interference of carbonate may be obviated by evaporating the soil with an aqueous solution of sulphurous acid. The advantages of the Dennstedt method are said to lie in the fact that the results are more accurate and one can determine at the same time the loss in weight of a soil by incineration.

Physically bound water of the soil was determined by four methods, viz. in the toluol drying oven at 105° C. (for 3, 6, 9, and 12 hours), in a vacuum desiccator over phosphorus pentoxid according to Mitscherlich, at 105° C. in the air bath to constant weight, and by the Schwalbe distillation method.⁹ It is concluded that for sandy soils drying in the air bath to constant weight between 105 and 106° C. will yield satisfactory results. In loam clay and moor soils the method of Mitscherlich or the distillation method of Schwalbe will serve best. As the latter method is exact enough for ordinary purposes, in view of the simplicity and speed with which it may be conducted, it is given preference over the Mitscherlich procedure.

For determining the specific gravity the von Wrochem^b modification of the Erdmenger and Mann method was found preferable to the pycnometer with water, and the pycnometer with oil of turpentine. In this method 20 gm. of the powdered substance in an absolutely air dry condition is placed in a 50 cc. flask containing 25 cc. of pure oil of turpentine run in from a 50 cc. burette. The mixture is then rotated several times to remove air from the soil pores and the flask is filled to the 50 cc. mark. The number of cubic centimeters of turpentine remaining in the burette divided by the weight of the soil employed equals the specific gravity of the soil.

A new test for soil acidity. E. Tatoc (*Wisconsin Sta. Bul.* 249 (1915), pp. 16, pl. 1, figs. 4).—A popular description of the test previously noted (E. S. R., 32, p. 610) with simple directions for making it. In order that the test may be carried out on the farm or field a compact form of apparatus has been devised which is illustrated. "The apparatus with accessories fits snugly into a small carrying case 5½ by 7½ by 9 in."

The availability of nitrogen in kelp. J. A. CULLEN (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 7, pp. 581, 582).—In view of the widespread interest in kelp as a source of American potash some information as to the value and nature of the nitrogenous substances present in this plant is reported. The methods used were the official alkaline permanganate method (E. S. R., 23, p. 9) and some modifications of it. The neutral permanganate method noted by Street (E. S. R., 23, p. 706) could not be used on account of a bulky residue and the resistance to filtration.

The official alkaline permanganate method, in its present form, was not suited for kelp, but by using increased amounts of potassium permanganate a higher availability was obtained. If an adequate amount of potassium permanganate is used to oxidize all the organic matter present, all, or nearly all, of the nitrogen is found available.

The chemical examination of water, sewage, foods, and other substances. J. E. PEARIS and T. R. HODGSON (*Cambridge, Mass.: Harvard University Press*, 1914, pp. 228).—This is intended as a text-book for the use of students of public health, health officers, and food chemists. Chemical analysis of water, sewage,

^a Ztschr. Agnew. Chem., 21 (1908), Nos. 9, pp. 400-402, fig. 1; 45, pp. 2311, 2312.

^b Mitt. K. Materialprüfungsamt Gross-Lichterfelde West, 22 (1904), No. 5, pp. 217-220, figs. 3.

and sewage effluents is considered in the first chapter, but the bulk of the text deals with the chemical examination of miscellaneous food products. Selected analytical methods which have been employed by the authors in their laboratory are described, and information is given regarding the natural properties of foods, the detection of poisonous metals, and preservatives in foods. Chapters are also devoted to gas and urine analysis.

The determination of carbon by the wet method. F. H. THINS (*Chem. Ztg.*, 38 (1914), No. 11, pp. 115, 116, figs. 2).—An improvement of the author's method which allows the estimation of halogen and nitrogen at the same time with the carbon. The products of oxidation obtained with potassium dichromate sulphuric acid mixture are passed over heated lime to absorb the halogen and part of the carbon dioxide and then through a weighed soda lime tube to absorb the remaining carbon dioxide. If iodine is present silver nitrate is added to the oxidation flask to retain the iodine as silver iodide. In this case bromine and chlorine are not retained.

Triketohydrindene hydrate: A method for the quantitative estimation of the NH_2COOH group. E. HERZFELD (*Biochem. Ztsch.*, 53 (1914), No. 3-4, pp. 249-259).—The method consists of evaporating the substance under examination with triketohydrindene hydrate or ninhydrin (E. S. R., 26, p. 504) and taking up the residue with alcohol. The extinction coefficient of the solution is measured by the spectrophotometer. The method has been applied to the dialyzate obtained in the Abderhalden method for diagnosing pregnancy (E. S. R., 31, pp. 275, 276).

The determination of invert sugar in the presence of saccharose. E. SAILLARD (*Jour. Fabric. Sucre*, 55 (1914), No. 3, p. 1; *abstr. in Chem. Ztg.*, 38 (1914), No. 41, *Repart.*, p. 195).—In the presence of sucrose, as Possz has long since shown, only solutions containing a small amount of free alkali or none at all should be used in making the determination. It is claimed that Bertrand's method does not yield reliable results in the presence of sucrose.

Modification of Clerget's method for the estimation of sugar in molasses. V. STANIZ (*Ztsch. Zuckerind. Böhmen*, 33 (1914), No. 9, pp. 429-440, fig. 1; *abstr. in Jour. Chem. Soc. [London]*, 106 (1914), No. 621, II, pp. 516, 517).—In the process described the molasses is decolorized, clarified with bromine and polarized in the presence of definite quantities of citric acid and potassium chlorid. The bromine has no effect upon sucrose and invert sugar.

Two citrate solutions are employed and are prepared by mixing 380 gm. of potassium hydroxid with 250 cc. of water. When about three-fourths of the hydroxid has dissolved, the solution is decanted and 400 gm. of citric acid mixed with 500 cc. of water added to it. The remaining hydroxid is then dissolved in water and added to the citrate solution until the latter is feebly alkaline to phenolphthalein: the solution is now cooled and diluted to 1 liter (neutral citrate solution). Five hundred cc. of this solution is then mixed with 250 cc. of hydrochloric acid (specific gravity 1.158), and diluted to 1 liter (acid citrate solution). A double-normal quantity of the molasses is dissolved in water and diluted to 200 cc. Fifty cc. of this solution is transferred to a 100-cc. flask, 20 cc. of the acid citrate solution is added, and the mixture is diluted to 100 cc. with saturated bromine water: after filtration, the solution is polarized in a 200-mm. tube. A second quantity of 50 cc. of the molasses solution is now treated with 10 cc. of hydrochloric acid (1:1), inverted, cooled to 20°, 10 cc. of neutral citrate solution is added, and the solution is diluted to 100 cc. with bromine water. The reading is taken after the lapse of 20 minutes. An inversion-constant of 132.6 is employed in calculating the quantities of sucrose and invert sugar from the readings obtained at 20°."

Maple sap products and the Canadian standards, J. F. SNELL (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 10, pp. 507-515, figs. 2).—This discusses the history of the maple sugar industry (briefly), methods of manufacture, adulteration of maple sirup, composition of maple sugar sand, history of standards of maple products and the standards at present adhered to, methods of analysis, existing standards, value of the conductivity test for examining maple products (E. S. R., 31, p. 610), a scheme of rapid analysis (E. S. R., 31 p. 611), maple sugar making as an agricultural industry, analytical values of pure maple sirup, Canadian census returns on maple sap products in 1910, and a comparison of maple with other farm products in the Province of Quebec for 1911.

Detection of added water in milk by a simplified molecular concentration constant, L. MATHIEU and L. FERRÉ (*Ann. Falsif.*, 7 (1914), No. 63, pp. 12-21; *abs. in Jour. Soc. Chem. Indus.*, 38 (1914), No. 4, p. 214).—"The simplified molecular concentration constant denotes the sum of the weight of crystallized lactose and of the sodium chlorid expressed as the isotonic equivalent of lactose. For instance, a milk containing 54.5 gm. of lactose and 1.4 gm. of sodium chlorid per liter would give a constant of $54.5 + (1.4 \times 11.9) = 71.2$, since 1 gm. of sodium chlorid is the isotonic equivalent of 11.9 gm. of lactose. The constant must be corrected for the volume of the fat and casein; the volume of the calcium phosphate may be neglected. This correction, taking extreme cases, varies from 1.03 to 1.1 and in the majority of milks it is 1.07; that is to say, the constant found as above must be multiplied by 1.07 to give the true value. With most milks the value of the constant lies between 74 and 79 and will fall below 73 when the milk contains from 5 to 8 per cent of added water."

Uniform acidity degree for the testing of milk, W. MORRES (*Milchw. Zentbl.*, 43 (1914), No. 9, pp. 229-233).—A criticism of existing standards and methods for the acidity of milk. The A. Marshall modification of the Dornic method which consists of using 9 cc. of milk and titrating with 1 decinormal sodium hydroxid solution is recommended. By this procedure a direct result is given.

Estimation of the fat content according to Kooper and total solids determination according to Mai and Rheinberger in cheese, KLOSE (*Milchw. Zentbl.*, 43 (1914), No. 9, pp. 225-229).—In a comparative study of the Kooper (E. S. R., 30, p. 207), the Wendler neu-sal (E. S. R., 30, p. 208), and the Bondzynski and Ratzlaff (E. S. R., 16, p. 440) procedures for determining fat in cheese of various kinds, the highest results were obtained by the last-named method, followed by the Kooper method. The results by the Wendler neu-sal were most unfavorable.

A study of methods for total solids included those of Mai and Rheinberger and the sea-sand method (drying the cheese in sea sand to constant weight without preliminary drying). In the Mai and Rheinberger method three-quarters of an hour of distillation did not always give the correct result. The temperature at which distillation is done is of great moment and should not exceed 200° C., as otherwise it yields low results. It is further necessary, in order to get results comparable with those given by the sea-sand method, to allow the petroleum layers to become thoroughly clear.

A new method for the determination of zinc in treated wood, M. H. BEDFORD and R. PFANSTIEL (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 10, p. 811, figs. 2).—The various methods proposed for determining zinc in wood treated with zinc chlorid are based upon the manner in which the organic matter is destroyed. In the case of hardwoods, particularly red oak, it was found that certain organic compounds were not destroyed by some of the ordinary processes. A modification of the methods in use was therefore attempted, the present investigation being carried out entirely with red oak.

"The details of the procedure adopted are as follows: Three gm. of red oak sawdust, previously dried at 110° C., is treated with 1 cc. of zinc chlorid solution equivalent to 0.035 gm. of metallic zinc and dried at 110° . The sawdust is then mixed with 35 gm. of sodium peroxid and fired in the bomb. After the explosion the bomb is cooled in water, and distilled water added through the plug. The contents are dissolved by heating on a water bath. The solution is then transferred to a beaker, acidified with concentrated hydrochloric acid, and boiled for a few minutes. Two gm. of citric acid, 10 cc. concentrated nitric acid, and 5 cc. of 8 per cent ferric chlorid solution are added. The solution is then made alkaline and 2 cc. excess of concentrated ammonium hydroxid is added. After dilution to 400 cc., the solution is titrated at 80° with potassium ferrocyanid. An outside indicator of equal parts of glacial acetic acid and glycerin is used.

"The potassium ferrocyanid solution is made by dissolving 5 gm. of the salt in 1 liter of water and is standardized against the zinc chlorid solution under the same conditions as exist in the charge. A blank is also run on 3 gm. of the untreated wood and subtracted from each determination. It is necessary to keep the conditions the same throughout the titration. An excess of ammonia is necessary to keep the solution from turning blue, but a large excess prolongs the end point. The time required for a determination is about 25 minutes. The accuracy of this method is shown by a set of six consecutive determinations."

Apple sirup and concentrated cider: New products for utilizing surplus and cull apples. H. C. GORE (*U. S. Dept. Agr. Yearbook 1914, pp. 227-244, figs. 2*).—The first part of this paper gives directions for preparing apple sirup, from cull and other apples too small for retail sale, for home use on the farm and on a commercial scale. Essentially the process consists in treating the expressed apple juice with milk or carbonate of lime (the latter is preferred for sirup making in the home) for the purpose of removing malic acid, and after clarification condensing to the proper concentration. In the commercial manufacture of sirup, especially as a by-product of a steam cider mill, the juice after neutralizing is treated with finely bolted infusorial earth (17.5 lbs. to 100 gals. of neutralized juice) and filtered through a filter press. The filtered juice is then evaporated to the proper consistency.

The cost of making sirup on a commercial scale as nearly as can be determined is probably slightly greater than making sirup from cane or sorghum. The cost of sirup exclusive of investment and depreciation charges, and of fuel and labor, which vary in different localities, is about 45 cts. per gallon. The malate of lime may eventually be sold to chemical firms preparing malic acid.

Some recipes for cooking and candy making developed in the Office of Nutrition Investigations are included.

The second part of the paper deals with the concentration of sweet cider by freezing as a fall activity for ice and cold-storage plants in apple sections. In experiments on a commercial scale in concentrating apple juice by artificial freezing during the apple-bearing seasons of 1913 and 1914, in connection with a cider mill located near a commercial ice-making plant in the apple-growing regions of Oregon, it was found that 5 gal. of apple juice could be reduced to 1 gal. of sirupy cider concentrate. "It was found that while the concentrated cider would not keep indefinitely under household conditions, its larger percentage of sugars and acids kept it from fermenting as quickly as ordinary cider. When kept cool, as in a household refrigerator, concentrated cider, it was found, would not spoil for many weeks. When kept at or below 32° F. in cold storage it was found that concentrated cider could be kept from one season

to the next and thus make fresh cider available [by simply diluting the sirup with water] as a beverage during the summer months."

The method calls for but slight additions to the ordinary equipment of an ice-making or cold-storage plant. A brief description of the manufacture of this concentrated cider on a commercial scale and the machinery necessary is given. The estimate of the cost per gallon for the preparation of cider concentrated by freezing—that is, for raw material, freezing, labor, filtering, power, interest, depreciation, superintendence, and other charges—is about 50 cts. per gallon.

Methods followed in the commercial canning of foods, A. W. BITTING (*U. S. Dept. Agr. Bul. 196 (1915), pp. 79, pls. 3*).—A revision of the Bureau of Chemistry Bulletin 151 noted previously (*E. S. R., 27, p. 313*), incorporating a summary of results of experiments carried out, especially in the experimental laboratory established at San Francisco in 1912, during the seasons of 1912 and 1913. "The general plan of the experimental work in canning involved the use of underripe, prime ripe, overripe, and spoiled fruits of all the varieties canned, to determine the appearance and effect upon the finished product. . . . The object throughout all the experiments has been to duplicate factory operations and not to attempt to make mathematical standards." Certain phases of the manufacturing processes have been enlarged upon.

Microscopical studies on cotton, A. HERZOG (*Chem. Ztg., 38 (1914), Nos. 114-115, pp. 1089-1091, figs. 3; 116-117, pp. 1097-1100, figs. 6*).—The first portion of this work deals exclusively with the dead or unripe cotton fiber. This type of fiber is thin-walled and when woven into cloth has a tendency to show up as knots. Part 2 of the work considers the beard fiber of cotton, and part 3 discusses the determination of the mercerizing capacity of cotton fibers with the microscope.

METEOROLOGY.

Popular misconceptions concerning the weather, A. H. PALMER (*Pop. Sci. Mo., 86 (1915), No. 2, pp. 128-141*).—The author points out, among other things, that, contrary to popular belief, the weather is not influenced by phases of the moon or the position of the planets; there is no connection between weather and earthquakes or magnetic disturbances; forests have much less influence on weather than has been supposed; the climate is not changing; there is no known relation between the weather of one day, season, or year and that of the following day, season, or year; while storms follow pretty well-defined tracks, they have no one starting point; there is no such thing as Indian summer as popularly understood; animals have no previous knowledge of weather changes; concussions do not cause precipitation; cold waves are not generally produced from the descent of cold air from above, but are "caused primarily by the horizontal transportation of huge masses of cold air from the cold continental interior, and are heightened by the increased radiation from the ground through clear, dry air thus brought in;" night air is not essentially different from day air; the importance of ozone in the air is popularly overestimated; the so-called equinoctial storm is a fiction; thunderstorms do not follow valleys; and lightning may strike many times in the same place.

Emphasis is laid upon the fact that too much importance is generally attached to mean and not enough to extreme conditions of the weather. Attention is called to the fact that there is rather widespread misconception as to the sources of rainfall and hail.

Story of the thermometer and its uses in agriculture, A. H. THIESSEN (*U. S. Dept. Agr. Yearbook 1914, pp. 157-166, figs. 4*).—This article discusses the his-

tory and construction of the thermometer and explains its use in candy making and cooking, in the dairy, in the incubator, and in orchards, as well as occasional uses, such as in the detection of fever in farm animals.

The variation with meteorological conditions of the amount of radium emanation in the atmosphere, in the soil gas, and in the air exhaled from the surface of the ground at Manila, J. R. WRIGHT and O. F. SMITH (*Phys. Rev.*, 2. ser., 5 (1915), No. 6, pp. 459-482, fig. 1).—In continuation of observations previously reported (*E. S. R.*, 31, p. 511), an attempt was made to determine definitely to what extent the amount of radium emanation in the air is dependent on weather conditions. The methods used were substantially the same as those employed in the previous observations.

As a result of observations extending over about 13 months, the variation of the radium-emanation content of the atmosphere was found to follow quite closely the variations in rainfall and wind movement. "The ratio of the maximum to the minimum for the year was found to be approximately as 10:1. The mean of the monthly means gives for the radium equivalent of the emanation per cubic meter of air a value of 71×10^{-12} gm. The month of January shows the highest monthly mean for the radium-emanation content, the minimum value for the rainfall, and a low value for the total wind movement. The month of July gives the lowest monthly mean for the emanation content, the maximum value for the rainfall, and the highest total wind movement. Every other month of the year shows a very similar relation. No direct connection has been discovered between the emanation content and atmospheric pressure or humidity. The effect of the direction of the wind seems at best very indefinite."

The emanation content was considerably greater during the night than during the day. "Observations for the interval from 11 p. m. to 5 a. m. gave a mean value 3.31 times greater than the mean value for the interval from 11 a. m. to 5 p. m. This variation has been found to be closely related to the variation in the total wind movement during the period, a high value of the wind movement corresponding to a low value of the emanation content.

"The rate at which radium emanation is exhaled from the surface of the ground shows a decided decrease after periods of heavy rain. This decrease has been found in some cases to be almost 60 per cent of the rate of exhalation for fair weather."

The radium-emanation content of soil gas was determined at depths of 30, 70, and 120 cm., respectively. The variation in the radioactivity of the gas collected at a depth of 30 cm. was found to follow closely the variation in the emanation exhaled from the surface of the soil, a decrease in the exhalation resulting in a corresponding increase in the emanation content of the soil gas. Soil gas collected at depths of 70 and 120 cm. showed only slight variations with the weather conditions. "The average value of the emanation content for the gas collected from the 120-cm. pipe was found to be a 304.5×10^{-12} gm. per liter, or over 4,000 times the mean value for atmospheric air. The mean value for the 30-cm. pipe was only about one-seventh that for the 120-cm. pipe."

[Meteorological observations], R. O'CONNOR ET AL. (*Ann. Rpt. Dept. Agr. Trinidad and Tobago, 1913-14*, pp. 34, 61-67).—Tables show the rainfall during the year ended March 31, 1914, at River Estate, from 1862 to 1913, inclusive, at the Royal Botanic Gardens, and for the calendar year 1913 at other places in Trinidad and Tobago, as well as various meteorological observations during 1913 and preceding years at the St. Clair Experiment Station, Trinidad.

Weather conditions (*Union So. Africa Dept. Agr. Rpt. 1913-14*, pp. 287-291).—The general weather conditions in the Union of South Africa during the

year ended March 31, 1914, are described and tables showing rainfall at various places in the country are given. It is stated that during the period named "the weather over the Union as a whole was characterized by practically the same features as during the preceding twelve months, viz. a shortage of rainfall, unusual warmth, hot, drying winds during spring, with unseasonable late frosts in the east and center of the Cape Province."

Relative reliability of long-time rainfall observations, F. H. MILLARD (*Engin. News*, 73 (1915), No. 25, p. 1212, figs. 2).—Studies of a 63-year rainfall record at Milwaukee, Wis., and of a 100-year record at New Bedford, Mass., to observe the maximum and minimum average rainfall per year obtained by combining consecutive years into groups of varying lengths, brought out the fact that "the variations above the average are considerably larger than the variations below the average, and that if one is to observe for a short period only, the variation above the average is likely to be appreciably larger than the variation below the average. . . . In one case the maximum single year exceeded the average by over 60 per cent, while the minimum year was less than the average by 40 per cent. In the other case the figures show a variation of 40 per cent above the average for the maximum and 26 per cent below the average for the minimum. Taking 10-year periods, the maximum is only 16 per cent greater than the average, while the minimum is 13 per cent less in one case, the maximum being 17 per cent greater and the minimum 7 per cent less in the other case."

Average rainfall in the light of the New Bedford record, N. M. STINEMAN (*Engin. News*, 73 (1915), No. 25, p. 1213, fig. 1).—Studies of a 100-year rainfall record at New Bedford, Mass., to determine the value of records of much shorter duration are reported.

It was found that a 5-year record based on the New Bedford record is too short to give dependable results. The 10-year curve is more regular than the 5-year curve, but the 20-year averages vary from 4.2 per cent below the 100-year average to 6 per cent above. "Hence, during the entire century it would not have been possible to select any 20 successive years in which the average rainfall would have deviated by more than 6 per cent from the 100-year average."

Rainfall and production, L. McCook (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 5, pp. 389, 390, pls. 2).—Two charts, showing graphically the variations in annual rainfall and yields of wheat and number of sheep in Queensland from 1873 to 1914, are given and briefly discussed.

The charts show the depressing effect on wheat yield of the droughts of 1888 and 1902, especially the latter, which followed six years of low average rainfall. The drought of 1888 had little effect on sheep production, but that of 1902 was disastrous. There was slow but steady expansion of wheat production and a more rapid increase in sheep production up to 1891. Thereafter wheat production rapidly increased while sheep production declined.

SOILS—FERTILIZERS.

Soil experiments on the level prairies of northeast Missouri, M. F. MILLER, C. B. HUTCHISON, and R. R. HUDELSON (*Missouri Sta. Bul.* 126 (1915), pp. 317-354, figs. 6).—These experiments were begun in one case in 1905 and in two cases in 1907. The soil on which the experiments were made is known as the Putnam silt loam, which includes practically all of the level prairie lands of northeast Missouri. "The surface soil consists of a gray to dark gray silt loam, from 8 to 10 in. deep, underlain by an ashy gray silt faintly mottled with yellow. . . . Beneath this is a clay subsoil, beginning abruptly at an average depth of about 18 in., which is made up of two layers. The upper layer is a

stiff, almost impervious, chocolate brown to grayish brown clay faintly mottled with red and from 6 to 10 in. in thickness. The lower layer is a silty clay, gray in color, mottled with yellow and brown. . . .

“The chemical analyses of the soil from this area show it to have a comparatively large supply of potassium and a fair supply of phosphorus. It is somewhat low in nitrogen and in vegetable or organic material. . . . These analyses also show that the soil is acid. . . . Another characteristic of the soil in question is the presence of a heavy clay layer in the subsoil which . . . interferes with drainage and air supply.”

The experiments were made on three fields in four series of five, nine, and eight $\frac{1}{2}$ -acre plats. The fertilizer treatments included the use of green manures, bone meal, rock phosphate, muriate of potash, ground limestone, and barnyard manure. The experiments indicate that when quick profits are necessary readily available forms of phosphorus would best be added to the soil.

“The important considerations in handling soils of this type are the adoption of a good crop rotation; the application of 2 or 3 tons of ground limestone, thoroughly worked into the soil, and followed by additional applications of 1 ton every six years; the use of all the manure possible to secure at a cost not exceeding \$1.50 per ton, including hauling and spreading it on the field—this to be applied chiefly before the corn crop; and, finally, the application of 150 to 200 lbs. of steamed bone meal or acid phosphate to be drilled in with the wheat where this crop is used in the rotation.”

Soil experiments on the dark prairies of central and northeast Missouri, M. F. MILLER, C. B. HUTCHISON, and R. R. HUDELSON (*Missouri Sta. Bul. 127 (1915), pp. 355-384, figs. 7*).—The soil on which these experiments were conducted is the Grundy silt loam, which occupies the undulating to gently rolling prairie of northeast and north-central Missouri. It “consists of a very dark brown to nearly black silt loam, 9 to 12 in. deep, gradually becoming lighter in color with increasing depth. The subsoil consists of a dark drab, plastic clay loam changing at 30 in. to a yellow gray silty clay mottled with brown.”

The experiments were conducted on three fields, in three, four, and one series of five, eight, and five plats, respectively. The fertilizer treatment on the first field included the use of green manures, ground limestone, bone meal, and muriate of potash, and on the second field rock phosphate and barnyard manure were used in addition. The rotation on the second field was one of corn, oats, wheat, and clover, substituting cowpeas for the clover in case of clover failure. The experiments on the third field were planned chiefly as a test of the effect of catch and cover crops on soil fertility, and included also a test of bone meal and rock phosphate in combination with pasturing.

The results of the experiments indicate that this soil is deficient in both nitrogen and organic matter and that the supplies of phosphorus and potassium, while considerably above those of an average soil, are largely in unavailable forms. The soil is also acid.

Some profit was derived from all the treatments except cowpeas drilled in the corn at the last cultivation for a green-manure crop. “The use of manure and lime have both brought consistent and valuable net returns, while good average net returns have also been secured from the use of phosphorus, and fair returns from the use of potassium.”

Specific recommendations for the management of this soil to increase its productiveness are given.

Soil experiments on the rolling glacial land of north Missouri, M. F. MILLER, C. B. HUTCHISON, and R. R. HUDELSON (*Missouri Sta. Bul. 128 (1915), pp. 385-401, figs. 4*).—The soil on which these experiments, begun in 1907, were con-

ducted consists of weathered glacial till and is classified as typical Shelby loam. "The surface soil is a very dark brown loam to fine sandy loam, changing at about 10 in. to a light brown or grayish brown heavy loam faintly mottled with reddish brown. The subsoil below 18 in. is a light brown or yellowish brown stiff sandy clay, usually mottled brown and gray in the lower portion. The surface soil and the lower subsoil contain more sand than the middle portion of the soil section."

The experiments were made on four series of seven plats. The fertilizer treatment included the use of green manures, barnyard manure, bone meal or rock phosphate, potassium chlorid, and ground limestone. The rotation practiced consisted of corn, oats, wheat, and clover, with cowpeas substituted when clover failed.

The results of the experiments and of chemical analysis indicate that this soil is somewhat acid, is low in its supply of nitrogen, organic matter, and phosphorus, and is apparently well supplied with potassium. Additions of bone meal and potash brought good returns and lime brought fair returns, while the use of complete fertilizers and lime nearly doubled the cost of treatment.

Specific recommendations for the management of this soil to increase its productiveness are given.

Soil experiments on the red limestone upland of southwest Missouri, M. F. MILLER, C. B. HUTCHISON, and R. R. HUDELSON (*Missouri Sta. Bul. 129 (1915)*, pp. 403-421, figs. 5).—This is the second report on soil experiments which have been previously described (*E. S. R.*, 23, p. 21). It is stated that the most marked return secured from the soil treatments given in these experiments has been with phosphates, the second with potash, and the third with lime.

A careful system of rotation including an abundance of legumes with free use of phosphates and some potash is suggested as the best treatment for this type of soil. "Rock phosphate may be used as a part of the phosphate application where much organic matter is added to the soil. From 800 to 1,000 lbs. per acre may be used once in 6 to 8 years. This should be supplemented with readily available phosphates and some potash, applied before wheat."

Soil experiments on the gray prairie of southwest Missouri, M. F. MILLER, C. B. HUTCHISON, and R. R. HUDELSON (*Missouri Sta. Bul. 130 (1915)*, pp. 423-442, figs. 4).—This is a second report on experiments begun in 1906 (*E. S. R.*, 23, p. 20).

The soil on which the experiments were conducted is the Cherokee silt loam, which is said to be derived chiefly from a fine argillaceous shale. "It is from 8 to 10 in. in depth, of a gray color, and somewhat ashy in appearance. From 10 to 18 in. in depth it is a lighter gray in color with a yellowish tinge. At about 20 in. it abruptly becomes heavy and sticky and is somewhat mottled with reddish brown. From 20 to 30 in. in depth this mottled plastic layer is very heavy. Below 40 in. the texture is somewhat coarser. . . . The chemical analysis of this soil shows it to be deficient in all the main elements of fertility, particularly in nitrogen. The shortage of phosphorus and potassium is distinct but not quite so marked." The soil in general is acid. The subsoil contains less nitrogen and potassium and more phosphorus than the surface soil and is only slightly more acid.

The experiments were made on three series of seven $\frac{1}{8}$ -acre plats. The fertilizer treatment included the use of green manures, bone meal, muriate of potash, and ground limestone. The rotation consisted of corn, cowpeas, wheat, and clover, with oats substituted for wheat and cowpeas for clover in several cases.

The eight years' experiments show that "the most profitable system of soil management tried is one using green manure catch crops to supply organic matter and nitrogen, bone meal to supply phosphorus, and chlorid (muriate) of potash to supply available potassium. Lime has not proved profitable as an average of the entire period, though it was profitable during the first two or three years." The results of seven years' tile draining experiments show that "the increased yields. . . with tile laid at intervals of 6 rods, have paid the cost and a fair rate of interest on the investment." The results of blasting experiments on this soil showed that an average annual increase in crops valued at \$1.60 per acre was obtained, while the cost of the blasting was \$12 to \$15 per acre.

Specific recommendations for the management of this soil to increase its productiveness are given.

[Soil experiment fields] (*Missouri Sta. Bul. 131 (1915), pp. 492, 493, fig. 1*).—For several years the station has maintained experimental fields in different parts of the State. Twelve of these are known as soil fields, being devoted primarily to the study of soil problems. The results obtained on these fields have been reported in detail from time to time in bulletins of the station (see above). The more important of these results are briefly summarized as follows:

"(1) Phosphorus is the element which can be applied with the largest net return on Missouri soils. (2) The best form of phosphate to apply under average conditions is one of the available phosphates, such as bone meal or acid phosphate. Rock phosphate brings slower returns and is adapted largely to the man who has time to wait for results and capital to invest. (3) Lime brings a small but rather consistent return on practically all the fields under experiment. These fields, however, are those more likely to need lime than a great many soils in Missouri. (4) Barnyard manure is worth about \$1.65 per ton as measured by crop increase and as an average of all experiments conducted."

Sketch of the geology and soils of the Cahuilla Basin, E. E. FREE (*Carnegie Inst. Washington Pub. 193 (1914), pp. 21-33, pls. 3*).—The author deals with the descriptive and historical geology of the basin and discusses the origin and character of the soils.

The two soil types represented in the basin are the desert soils of the slopes and the river alluvium soils of the Colorado Delta. The former are mainly sandy and gravelly, are mineralogically very heterogenous, and are amply supplied with useful soil-forming minerals. The alluvial soils are similarly diverse and fertile, but differ in that their mineral particles are somewhat weathered and are more uniform in size. Practically all of them are silts or very fine sands, their chief fault, aside from the frequent presence of alkali in the silts, being too great heaviness and difficulty of working. The sandy soils are seldom alkaline.

It is stated that the submergence of the soils by the waters of the Salton Sea seems to have had little effect upon their alkali content. It is also stated that no direct influence of the soils upon the local distribution of vegetation was discernible.

The colloidal properties of the acid soils of Japan, T. TADOKORO (*Jour. Col. Agr. Tohoku Imp. Univ., 6 (1914), No. 5, pp. 117-129, figs. 2*).—In continuation of previous work along the same line (E. S. R., 32, p. 318), the author reports experiments in which he compared the colloidal properties of neutral sand, clay, and humus soils with those of acid soils as determined in the previous experiments.

In the experiments with the neutral soils it was found that the increase of the volume by swelling on treatment with reagents, the adsorptive power for coloring matter, and the absorption coefficient for ammonia were greatest

in the humus soil and least in the sandy soil. The differences between sandy and clay soils as regards adsorption of coloring matter were very great. The increase in adsorption of coloring matter with variations in its concentration were least in the sandy soil. The hygroscopicity was greatest in clay and least in the sandy soil.

The degree of swelling of mineral acid soils was generally greater than that of neutral soil rich in humus. This difference was greatest on treatment with sodium carbonate and caustic soda solutions. On the other hand, the volume of swelling of some of the acid soils was less than that of neutral soils poor in humus.

The variations in the volume of swelling on treatment with reagents, according to the type of reagent, were much greater with mineral acid soils than with neutral soils. This is taken to indicate that the mineral acid soils contain considerable quantities of colloidal substances showing movable, unstable forms.

The hygroscopicities of the different mineral acid soils were not markedly different from those of neutral soils, but the relation of the volume of swelling to hygroscopicity for mineral acid soils was generally greater than for neutral soils, excepting in the case of acid soil rich in humus.

The adsorptive power of mineral acid soil for coloring matter was generally greater than that of neutral soil. The relations of adsorptive power to hygroscopicity for mineral acid soils were generally greater than for neutral soils excepting in the case of acid soil rich in humus. The ammonia absorbing power of acid soil was generally greater than that of neutral soil, but there was little difference between the smallest values of the former and the greatest values of the latter. The increase of the coefficient of ammonia absorption was not greater for acid soil rich in humus and for neutral soil than for mineral acid soil.

How great is the surface of a gram of surface soil? P. EHRENBURG (*Fühling's Landw. Ztg.*, 63 (1914), No. 23, pp. 725-735).—The author briefly reviews the work of others on the subject, and points out that while the results obtained by most investigators as to the surface of a gram of soil correspond closely those obtained by Mitscherlich on the basis of hygroscopicity are quite different.

From computations based on the assumption that the thickness of the surface film of hygroscopic water in soils is equal to the diameter of a molecule of water, it is concluded that the results obtained by Mitscherlich are, on this basis, double what they should be. Other data are reviewed which would indicate that the thickness of the surface film of hygroscopic water more nearly approaches the sum of the diameters of ten molecules, and it is stated that if computed on this basis the results obtained by Mitscherlich would correspond approximately to those obtained by other investigators.

It is further stated that according to his studies there are always many unknown factors present affecting the determination of the absolute surface of a soil, and that the results obtained can, therefore, give only an approximate indication of the actual facts.

Investigations on the influence of plant roots on the structure of the soil, M. BERKMANN (*Untersuchungen über den Einfluss der Pflanzenwurzeln auf die Struktur des Bodens.* Diss. K. Tech. Hochsch. München, 1913, pp. 55, figs. 6).—This article has been noted from another source (E. S. R., 30, p. 120).

The gases of swamp rice soils.—II, Their utilization for the aeration of the roots of the crop, W. H. HARRISON and P. A. SUBRAMANIA AIYER (*Mem. Dept. Agr. India, Chem. Ser.*, 4 (1914), No. 1, pp. 17, pl. 1, figs. 2).—In continuation of previous work (E. S. R., 30, p. 515) a series of experiments made to de-

termine the action of the soil surface film on the soil gases and the nature of the agents to which the changes produced could be ascribed are reported.

It was shown in the previous report that the gases formed in swamp rice soil apparently have an important connection with the aeration of the roots of the crop. It was found in the later experiments that "the organized film in contact with the surface of swamp rice soils utilizes the soil gases in such a manner as to bring about an increased oxygen output from the film leading to a correspondingly increased root aeration. The film contains bacteria which possess (1) the power to oxidize methane and hydrogen, and (2) to assimilate directly methane and carbon dioxide. These changes either directly or indirectly result in the production of CO₂ which is in turn assimilated by the green algae with the evolution of oxygen. . . .

"The practice of green manuring, by increasing the output of the soil gases, brings about an increased activity on the part of the film resulting in an increased oxygen production and root aeration. An important indirect function, then, of green manuring is to bring about a greater root aeration and so induce greater root development and cropping power.

"The oxygen concentration of the water entering the soil appears to be one of the main factors which regulates the growth of the crop."

Effect on soil moisture of changes in the surface tension of the soil solution brought about by the addition of soluble salts, P. E. KARRAKER (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 2, pp. 187-192, figs. 2*).—Experiments are described in this paper, the results of which indicate that changes in the surface tension of the soil solution arising from the application of fertilizer salts are of no importance in affecting the moisture condition of the soil.

The effect of different methods of preparing a seed bed for winter wheat upon yield, soil moisture, and nitrates, L. E. CALL (*Jour. Amer. Soc. Agron., 6 (1914), No. 6, pp. 249-259, figs. 2*).—Investigations, extending over five seasons, on the influence of different methods of preparing the seed bed for winter wheat upon conservation of moisture, liberation of plant food as indicated by available nitrogen, and the growth of the crop as determined by the production of grain and straw are reported. The soil used is a dark brown silt loam about 10 in. deep, the subsoil to a depth of at least 6 ft. being a reddish-brown silty clay loam.

The results obtained demonstrate the value of working ground plowed early, and also show the importance of early plowing even though it is impossible to work the ground as quickly as it should be worked after the plowing is done. "Ground worked early, regardless of the method of working, has usually produced a comparatively high yield, while ground worked late, regardless of the method, has usually resulted in a low yield. . . .

"There is very little, if any, correlation between the amount of moisture in the soil at seeding and the yield of wheat secured. . . . Those plats which produced high yields used nearly if not quite all of the available moisture in the soil, while the low-yielding plats left in the soil from 1.5 to 5 per cent of available moisture. Apparently, the low yield was not the result of a deficient supply of moisture."

The yield of wheat bore a close relation to the nitrates in the soil at seeding. Fertilization with sodium nitrate did not increase the yield of wheat on the field plowed in July, but on corn ground, where a seed bed was prepared for wheat by double disking the ground after the corn crop was harvested, fertilization with the same quantity of sodium nitrate increased the yield nearly 100 per cent. "It appears, therefore, that on late-plowed ground or on ground

otherwise worked late, nitrogen was not liberated in sufficient quantities to supply the crop with the amount necessary for the maximum growth, and under such conditions a lack of nitrogen has been responsible for the low yields of wheat secured. On the other hand, where the ground was prepared early in the season, sufficient nitrogen was liberated to supply the needs of the plant and additional nitrogen in the form of nitrate of soda did not increase the yield."

The action of liquid manure as a nitrogenous fertilizer, A. STUTZER (*Mitt. Deut. Landw. Gesell.*, 30 (1915), No. 6, pp. 68-70).—Briefly summarizing the results of experiments by various investigators, the author reaches the conclusion that liquid manure is a satisfactory nitrogenous fertilizer on heavy and medium soils which have the necessary absorptive capacity for ammonia and potassium carbonate. It, however, is not well suited to light nonacid sandy soils which have little absorbent power for ammonia. In such soils the liquid manure produces a persistent alkaline reaction, which is likely to cause burning of the plants. The best results with liquid manure are obtained on mildly acid humus soils.

Poultry manures, their treatment and use, W. P. BROOKS (*Massachusetts Sta. Circ. 54* (1915), pp. 4).—A revision of Circular 36 (E. S. R., 32, p. 322).

Imports and exports of fertilizer materials (*U. S. Dept. Com., Bur. Foreign and Dom. Com., Ser. 1914-15, No. 6, pp. 455, 456, 458, 478; Com. Rpts., No. 42* (1915), p. 694).—The following table gives a summary for the calendar years 1913 and 1914 of imports and exports by the United States of the principal fertilizing materials, as reported by the U. S. Department of Commerce:

Imports and exports (in long tons), of fertilizing materials by the United States, 1913 and 1914.

Materials.	1913		1914	
	Amount.	Value.	Amount.	Value.
IMPORTS.				
	<i>Tons.</i>		<i>Tons.</i>	
Bone dust and bone ash.....	34,619	\$836,682	36,022	\$890,672
Guano.....	19,105	538,183	25,562	762,688
Kainit.....	465,850	2,207,018	329,611	1,550,879
Manure salts.....	223,292	2,150,190	168,426	1,842,649
Muriate of potash.....	213,762	7,120,055	168,509	5,740,893
Sulphate of potash.....	39,538	1,633,114	36,264	1,568,704
Nitrate of soda.....	625,862	21,630,811	543,715	15,228,671
Sulphate of ammonia.....	58,281	3,957,307	74,121	4,475,603
All other substances.....		4,995,690		5,055,355
Total imports.....	1,680,309	45,069,050	1,382,230	37,116,114
EXPORTS.				
Phosphate rock, untreated:				
High-grade hard rock.....	473,533	4,735,330	281,806	2,818,060
Land pebble.....	891,263	5,255,416	681,241	3,948,079
All other phosphates.....	1,712	5,834	1,067	5,513
Total phosphates.....	1,366,508	9,996,580	964,114	6,771,652
All other fertilizers.....	72,747	1,666,755	63,554	1,311,227
Total exports.....	1,439,255	11,663,335	1,027,668	8,082,879

During the fiscal year ended June 30, the imports of calcium cyanamid were approximately 15,000 tons in 1913 and 30,000 in 1914; of basic slag 15,000 tons in 1913 and 10,000 in 1914; of crude phosphates 24,000 tons in each year; and of apatite 3,000 and 100 tons, respectively. The potash salts imported contained 228,757 tons of actual potash (K₂O) in 1913 and 176,354 in 1914.

“The decrease in imports of potash salts extends to other groups used in the chemical and other manufacturing industries. Carbonate of potash fell from 21,500,000 lbs. in 1913 to 16,000,000 lbs. last year [1914]; nitrate of potash, from 10,000,000 to 2,250,000 lbs.; caustic potash, from 8,500,000 to 7,250,000 lbs.; and other salts, except the cyanid, from 6,000,000 to 5,000,000 lbs. Cyanid of potash slightly increased, from 1,000,000 to about 1,250,000 lbs.”

Fertilizer markets (*Oil, Paint and Drug Reporter*, 87 (1915), No. 11, pt. 2, pp. 46, 47).—This is a concise review of the fertilizer trade of the United States during 1914, giving data for production, consumption, and prices for nitrate of soda, sulphate of ammonia, fish scrap, phosphate rock, and potash salts.

The chemistry of base goods fertilizer, E. C. LATHROP (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 3, pp. 228-233).—This article is based upon investigations which have already been noted from another source (E. S. R., 32, p. 217).

The preparation of fertilizer from municipal waste, J. W. TURRENTINE (*U. S. Dept. Agr. Yearbook 1914*, pp. 295-310, pl. 1).—This article discusses the composition and availability of sewage, street sweepings, dead animals, and garbage, as well as the processes and possibilities of converting these waste products into useful fertilizers.

It is estimated that the 199 cities of the United States having a population of more than 30,000 each, produce 3,600,000 tons of wet sewage sludge, or 720,000 tons of dry sludge, yearly, capable of producing 7,200 tons of ammonium sulphate worth \$480,000. The same cities produce over 5,000,000 tons of street sweepings, containing 0.44 per cent of nitrogen, 0.1 per cent of phosphoric acid, and 0.21 per cent of potash. The dead animals from these cities are capable of producing 25,000 tons of tankage worth \$500,000 and containing about 8 per cent of nitrogen and 10 per cent of bone phosphate. The present annual production of garbage tankage is roughly estimated at 150,000 tons, valued at \$975,000. This is obtained from 1,200,000 tons of raw garbage rendered in about 25 plants. The garbage collected in 1909 in the cities having a population of 30,000 or over amounted to 2,700,000 tons, capable of yielding 400,000 tons of dry tankage worth \$2,500,000.

Electro-manufacture of nitrates, M. ADAMS (*Jour. Electricity*, 34 (1915), No. 10, pp. 190-192, fig. 1).—Some of the leading processes used for this purpose are briefly described, and the possibility of their profitable utilization in Nevada for the production of nitric acid to be combined with the abundant natural supplies of sodium carbonate for the manufacture of sodium nitrate is discussed.

Ammonification of cyanamid, F. LÖHNIS (*Ztschr. Gärungsphysiol.*, 5 (1914), No. 1, pp. 16-25; *abs. in Chem. Abs.*, 9 (1915), No. 8, p. 1085).—Investigations are briefly reported which show that there are at least 14 fungi capable of transforming cyanamid nitrogen into ammonia. About one-half of these appear to be species of *Penicillium* and about one-half of the nitrogen present is transformed in cultures. In soils the cyanamid nitrogen is almost completely transformed, first into ammonia and later into nitrate, and this change is more rapid in sterilized than in unsterilized soil. It is suggested that the first step in this change, viz. the formation of urea, is due to the action of the colloid constituents of the soil, and that the further steps, ammonification and nitrification, are due to the action of different kinds of organisms.

Field experiments on the action of different nitrogenous fertilizers, GERLACH ET AL. (*Ber. Landw. Reichsanst. Innern*, No. 34 (1914), pp. 229).—The results of comparative tests of sodium nitrate, ammonium sulphate, lime nitrogen, calcium nitrate, calcium nitrite, and liquid manure on rye, oats, barley, wheat, potatoes, and beets by the experiment stations of Bernburg, Bremen, Breslau, Bromberg, Halle, and Jena are reported in detail.

Sodium nitrate produced about the same result whether applied in one dose or in two. Taking the average action of the sodium nitrate on rye, barley, oats, potatoes, sugar beets, and fodder beets as 100, the average of the action of ammonium sulphate on these crops and on wheat in addition was 84, of lime nitrogen on the same crops as in the case of ammonium sulphate 76, of calcium nitrate on the same crops 99, of calcium nitrite on oats, potatoes, and sugar beets 90, and of liquid manure on barley, oats, potatoes, and fodder beets 64.

As the average of all of the results, it was found that 61 per cent of the nitrogen applied in the form of sodium nitrate was recovered in the crop. Taking the recovery of nitrogen from sodium nitrate as 100, the recovery in the case of ammonium sulphate was 78, of lime nitrogen 65, of calcium nitrate 91, of calcium nitrite 54, and of liquid manure 57. The percentage of nitrogen in the crop was very slightly influenced by nitrogenous fertilizers. This was especially true in the case of the roots and tubers, but also true of leaves and vines. The influence of the nitrogenous fertilizers on the quality of the product was scarcely noticeable.

The action of different nitrogenous fertilizers, GERLACH (*Fühling's Landw. Ztg.*, 64 (1915), No. 1, pp. 1-7).—The results here reported are noted for the most part in the above.

The action of common salt in combination with ammonium sulphate, SCHNEIDEWIND (*Landw. Wchschr. Sachsen*, 17 (1915), No. 1, pp. 3, 4).—Field experiments with beets and wheat in which ammonium sulphate was used in combination with kainit and with 40 per cent potash salt mixed with twice its weight of common salt are briefly reported. The results indicated that the combination of ammonium sulphate with kainit is fully as effective and more economical.

The Perlis phosphate mines (*Indische Mercur*, 38 (1915), No. 8, pp. 133-135).—This article discusses the origin, extent, composition, and fertilizing value of the phosphates occurring in Perlis, the northernmost State of Siam. Analyses reported show that the phosphate contains about 21 per cent of phosphoric acid, about 10 per cent of which is soluble in 2 per cent citric acid, 2.7 of ferric oxid, 4.7 of alumina, 27 of lime, 0.43 of potash, and 0.32 of nitrogen, largely nitrates.

Double superphosphate, E. BERNARD (*Kiserlet. Közlem.*, 17 (1914), No. 5, pp. 709-724).—This article discusses briefly double superphosphates in general, but deals especially with the properties of a double superphosphate prepared by the author's method. This superphosphate is moderately hygroscopic, due to the presence of free phosphoric acid (about 11 per cent). The water-soluble phosphoric acid amounts to from 40 to 43 per cent, and the sum of the water-soluble and citric acid soluble phosphoric acid to from 44 to 46 per cent.

Ground limestone for sour soils, F. H. HALL (*New York State Sta. Bul.* 400, popular ed. (1915), pp. 8, fig. 1).—This is a popular edition of Bulletin 400, previously noted (E. S. R., 33, p. 26).

The fertilizer law and rules and regulations for its enforcement, B. H. HITE (*West Virginia Sta. Circ.* 16 (1915), pp. 11, fig. 1).—The text of the West Virginia fertilizer law enacted in 1901 and the rules and regulations promulgated under its provisions are given.

AGRICULTURAL BOTANY.

Department of botanical research, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book*, 13 (1914), pp. 63-104, figs. 5).—This is a progress report of the investigations carried on by members of the staff, collaborators, and re-

search associates, the greater part of the work being conducted at the desert laboratory near Tucson, Ariz. The investigations include further studies of physical, chemical, and biological phenomena in connection with the Salton Sea; an analysis of the effect of climatic complexes and various external factors upon plants; studies on photolysis, respiration, hydration, and growth; and various special investigations of Cactaceæ and other desert plants.

Notes on the production of tropical plants, E. DE WILDEMAN (*Notes sur des Productions Végétales Tropicales. Antwerp: E. Stockmans & Co., 1914, pp. 175*).—Compiled and original notes are given on a number of economic tropical plants, agricultural practices, plant diseases, etc., the substance of the several articles having already been presented in various publications.

Obligate symbiosis in *Calluna vulgaris*, M. C. RAYNER (*Ann. Bot. [London], 29 (1915), No. 113, pp. 97-133, pl. 1, figs. 4*).—This investigation was conducted to determine the precise ecological conditions associated with small, well defined communities of *C. vulgaris* in a restricted area of England.

In common with other members of the family Ericaceæ, *C. vulgaris* was found to possess a characteristic root mycorrhiza. The infection by the mycorrhizal fungus, it is said, takes place shortly after germination, the source of infection being the testa of the seed. The infection does not cease with the formation of the mycorrhiza associated with the roots, but affects all parts of the young seedling and most of the mature plant as well. The embryo and endosperm of the resting seed seem to be free from infection. It was found possible to sterilize the seed and germinate seedlings free from fungal and bacterial infection, but where the appropriate fungus was not present, seedlings did not develop roots and their growth was checked, although they remained alive for several months. The mycorrhizal fungus has been isolated and grown in pure cultures, and sterile seedlings inoculated, thus completing the synthesis of the fungus and the plant. It has not been found possible to replace the stimulus to development which follows seedling infection by supplying various organic nitrogenous substances to the plant.

A bibliography is given.

Andropogon halepensis* and *A. sorghum, C. V. PIPER (*Proc. Biol. Soc. Wash., 28 (1915), pp. 25-43*).—The results are given of a study of many forms of these grasses under cultivation, besides herbarium material in this country, at Kew, and Berlin. These two species of grass are generally treated as distinct species, although there have been published statements indicating that the latter species is derived from the former under cultivation.

As a result of his investigations the author considers a more satisfactory treatment of the plants to be to recognize them as two distinct species, *A. halepensis*, perennial plants possessing rootstocks, 5 subspecies or varieties of which are recognized, and *A. sorghum*, annual plants which become perennial in frostless regions and are without rootstocks. Of the latter species the author enumerates 11 varieties.

Additional evidence of mutation in *Oenothera*, H. H. BARTLETT (*Bot. Gaz., 59 (1915), No. 2, pp. 81-123, figs. 17*).—Studies are reported on mutants of *O. pratincola*, a small, recently described self-pollinating species from Kentucky, which were brought to maturity and have yielded a second generation.

The author states that this form is in a condition comparable with that of *O. lamarckiana*, the most striking of the mutations (called *O. pratincola nummularia*) occurring in strains from 7 wild mother plants out of 8 selected at random. Two of these strains give mutations in both the F_1 and F_2 generations from the parent plant and a third strain showed mutations only in the F_2 generation. The mutant appears with a fairly uniform frequency of 1 to every 300

to 400 of the seeds planted, a ratio not agreeing with the Mendelian hypothesis. The new form is better adapted than is the parent form to withstand influences unfavorable to germination.

The author thinks that selective germination and differential mortality among dormant seeds may be important factors in natural selection. He also holds that mutation is a process distinct from Mendelian segregation, and that the phenomena exhibited by *O. lamarckiana*, *O. biennis*, and *O. pratensis* can not be attributed to heterozygosis.

Cultural bud mutations in subterranean portions of *Solanum caldasii*, E. HECKEL (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 1, pp. 24-28).—In continuance of previous articles (E. S. R., 30, pp. 433, 529, 730), the author reports that he has obtained, from the same stock of *S. caldasii*, tubers some of which resembled the wild ancestors while others resembled in several respects cultivated varieties. This is considered a case of mutation.

The effect of salt on the growth of *Salicornia*, A. C. HALKET (*Ann. Bot. [London]*, 29 (1915), No. 113, pp. 143-154, pl. 1, figs. 4).—A series of experiments was conducted with *Salicornia* and *Suaeda* seedlings which were cultivated in the presence of various amounts of sodium chlorid, some being grown in soil treated with solutions containing various percentages of sea salt, while others were grown in nutritive solutions to which definite quantities of sodium chlorid were added.

The author found that *Salicornia oliveri* and *S. ramosissima* grow better in the presence of sodium chlorid than in its absence, the greatest growth taking place when between 2 and 3 per cent of this salt was present. With higher percentages of salt there was a decrease in the growth of the plants. The effect of sodium chlorid on the growth of *Suaeda maritima* was not so marked, the plants growing as well in its absence as when a small quantity (1 per cent) was present. Both *Salicornia ramosissima* and *Suaeda maritima* were found able to resist the presence of a large amount of sodium chlorid, the plants remaining alive and green with the salinity of water in the soil at times as high as 17 per cent, although they were not able to make any growth.

The growth of *Glyceria maritima* was found to decrease with an increase of salinity in the soil.

The total amino nitrogen in the seedlings of the Alaska pea, T. G. THOMPSON (*Jour. Amer. Chem. Soc.*, 37 (1915), No. 1, pp. 230-235).—An account is given of a study of the formation and distribution of amino acids and the acid amids in seedlings of the Alaska pea at various stages of growth (especially in the very young seedlings).

The author states that there is a steady increase in the percentage of amino nitrogen and a notable increase thereof on the first and the fifth day. This is explained as probably due to the rapid transformation of the seed and the requirement for a greater quantity of this sort of plant food to build up the highly elaborated nitrogenous material in leaves, stems, and roots. In case of seven-day seedlings it was found that the plumules contained a much greater amount of amino nitrogen, supposedly serving as a food supply for the newly forming leaves and stems.

Analysis of leaves and of stem near the top and near the roots of the plant showed that the total nitrogen remains fairly constant in the leaves, but that there is a noticeable decrease in the amino nitrogen. With increase in age the leaves and stems near the top and bottom show a decrease in both total and amino nitrogen when expressed in terms of dry material. The amino nitrogen in the stems near the lower part of the plant shows a slightly smaller percentage than is noted in the sample taken near the leaves. Results from the

older plants were somewhat impaired by difficulty in freeing them from foreign materials, but apparently they contain a smaller percentage of amino nitrogen than do the stems.

A note on the significance of sugar in the tubers of *Solanum tuberosum*, O. BUTLER (*New Hampshire Sta. Sci. Contrib.* 7 (1913), pp. 110-118, pl. 1, figs. 2).—A reprint of an article previously noted (E. S. R., 29, p. 219).

On the relation between the concentration of the nutrient solution and the rate of growth of plants in water culture, W. STILES (*Ann. Bot.* [London], 29 (1915), No. 113, pp. 91-96).—The results of a study with rye and barley in water cultures indicate that the variation over a fairly wide range of the concentration of the nutrient solution of rye and barley growing in water culture produces relatively little effect on the amount of dry matter produced. Below a certain concentration it is said there was a definite falling off in the rate of growth. The concentration of the soil solution, as estimated by Cameron (E. S. R., 26, p. 122), is said to be high enough to produce healthy plants. Frequent changing of the nutrient solution of water cultures, it is claimed, produces decidedly better growth of the plants. It is considered necessary to calculate the probable error of the results obtained in experiments with water cultures in order to determine the significance of differences between results from different sets of cultures.

An experimental study of the rest period in plants.—The summer rest of bulbs and herbaceous perennials, W. L. HOWARD (*Missouri Sta. Research Bul.* 15 (1915), pp. 25, pls. 4).—This is a second report (E. S. R., 23, p. 526) and relates to the summer rest of bulbs and herbaceous perennials.

From results of experiments with ether and other agents as described, it is concluded that most or all bulbous plants have a pronounced summer rest period, which is difficult to shorten or to break during its earlier stages with the means which prove effective in case of woody plants, but it is believed that this may be practicable by employment of temperatures not over 60° F. after treatment. Desiccation followed by injection with ether and Knop's solution, and combinations of these, seem to be the most effective treatments tested for shortening the rest period.

Experiments with a large number of species of herbaceous perennial plants showed that for most of these freezing was perhaps the best treatment for forcing early growth, but its effects were not cumulative. In case of plants already in leaf its effects were sometimes harmful, as were also those of etherizing, which proved very stimulating in some cases.

It is believed that several species of herbaceous perennials have a rest period, but that they may be aroused by proper treatments, frost, desiccation, and ether appearing to be the most effective agents.

An experimental study of the rest period in plants.—Pot-grown woody plants, W. L. HOWARD (*Missouri Sta. Research Bul.* 16 (1915), pp. 27, figs. 12).—This is the third report of this series, giving results of more recent work than that above noted. The author states that rest period studies with woody plants can be as safely carried out with twigs 12 to 15 in. long as with trees or shrubs growing in pots. It is held that the rest period and its interruption relates to the bud itself rather than to roots, cambium, or any tissue of trunk or branches. The roots of potted plants are not affected directly by the ether treatment.

It is considered probable that dormancy of plants depends upon suspension of enzym activity, awakening upon its resumption. It is thought that practically all woody forms rest for a longer or shorter period of time, and that all can be aroused by proper treatment, some more difficultly than others. Quickly responsive species are considered to be in a state of enforced and unnatural rest, due

to unfavorable growing conditions. When dormant woody plants are treated, growth first begins in the buds, regardless of root connection. Latent buds on old wood force with great irregularity. Ether is perhaps the most reliable rest breaking agent yet employed. Species vary greatly as regards dosage required.

The relative transpiration of white pine seedlings, G. P. BURNS (*Plant World*, 18 (1915), No. 1, pp. 1-6).—This is a detailed account of a paper previously noted (E. S. R., 30, p. 726), in which the author concludes that the differences in size and chemical composition of three groups of white pine seedlings under no shade, half shade, and full shade, are to be sought along the line of photosynthesis and assimilation rather than along the line of absorption and transpiration.

The visible effects of the Schumann rays on protoplasm, W. T. BOVIE (*Bot. Gaz.*, 59 (1915), No. 2, pp. 149-153).—A brief account is given of the violent visible effects of the Schumann rays (1,250 to 2,000 Angstrom units or 0.125 to 0.200 microns in wave length) on protoplasm.

Vesicle formation and the bursting of spores are considered to point strongly to changes in osmotic relations or in imbibition. These, it is thought, may be connected with the fact pointed out previously (E. S. R., 29, p. 130) that the longer ultraviolet light waves have the power to break down proteins. These rays are thought to possess a similar power in greater degree.

The later researches on anthocyan, P. Q. KEEGAN (*Chem. News*, 111 (1915), No. 2882, pp. 87, 88).—The author reviews some recent publications in which different opinions are expressed regarding the origin of anthocyanin, and gives a summary of his own conclusions regarding this matter, in which he states that plants producing phloroglucol tannins yield original reds only. Those plants producing caffetannin are said to yield original blues only. Plants which produce gallotannin seem inclined to display vivid violets or warm purplish blues, but never cold true blues.

It is claimed that there is only one anthocyanin pigment in plants producing caffetannin. The red appearing on stems or petals is here due to acid only. Yellow flowers owe their color to carotin or its diffused oxidized product, xanthophyll, and in rare instances to a flavone. White flower color often incloses a very dilute solution of anthocyanin. He claims that Grafe's opinion that a special chromogen of anthocyanin can not exist is incorrect so far as the specific hereditary tendency of the protoplasm to form certain kinds of tannin is concerned.

Micro-organisms in silage, EMMA B. MUNDY (*Missouri Sta. Bul.* 131 (1915), pp. 470, 471).—A study was made of *Monascus purpureus* or red mold, which is common in silage. It is stated that growth is vigorous on a neutral or slightly acid medium and feeble on an alkaline one, organic acids such as lactic and acetic being more favorable than inorganic acids such as hydrochloric. Oxygen is absolutely essential, but liquid and agar media do not seem particularly favorable. It grows well on a number of complex organic compounds, as certain sugars; also abundantly on such starchy materials as rice.

A variety of factors influence the production of the characteristic carmine red pigment, which is not necessarily correlated with abundant growth. The pigment, the solubility of which is discussed, is not due to simple oxidation, but is thought to be an end product of metabolism.

An improved nonabsorbing porous cup atmometer, J. W. SHIVE (*Plant World*, 18 (1915), No. 1, pp. 7-10, fig. 1).—A description is given of a form of porous cup atmometer in which the instrument is modified in such a way as to be self-contained and at the same time to reduce the liability of breakage and the difficulty of adjustment.

FIELD CROPS.

Dry-farming investigations in western North Dakota, J. C. THYSELL, H. C. MCKINSTRY, R. S. TOWLE, and A. J. OGAARD (*North Dakota Sta. Bul. 110 (1915), pp. 155-207, figs. 11*).—This bulletin presents a study of the annual and seasonal precipitation; evaporation; length of frost-free period; the soil moisture storage and reduction as affected by various crops; and rates of seeding and methods of tillage derived from data obtained at the stations at Dickinson, Hettinger, Edgeley, and Williston, N. Dak., in cooperation with the U. S. Department of Agriculture in determining the best methods of soil cultivation and crop rotation for the conservation of moisture and maintenance of humus.

It is noted that on account of the lack of an underground water table ordinary methods of cultivation which would develop a mulch are of no avail as a means of storage of soil moisture. Cultivation to prevent the growth of weeds proved more effective. In studying the reduction of soil moisture by plant growth it is shown that wheat roots penetrated to the sixth foot and corn roots to the fifth, as evidenced by the reduction of the moisture supply.

The following conclusions have been reached: "Climatic conditions are the chief determining factors in crop production in western North Dakota. The amount of rainfall during the growing season is a better criterion of crop production than is the annual rainfall. Available records show the average frost-free period to be 129 days at Edgeley, 119 days at Williston, and 110 days at Dickinson. Even with alternate cropping, water is seldom stored to a greater depth than that from which annual crops can recover it.

"While stored water may be of value in supplementing rainfall, it is unable in itself to mature a crop in western North Dakota. Shallow soils are not as responsive to tillage as are deeper soils. Prevention of the growth of weeds is a much more important function of cultivation than is the maintenance of a mulch. Summer tillage has a certain value as insurance against crop failure. It has not, however, increased average yields over those obtained by other methods enough to warrant giving it more than a secondary and temporary place in the agriculture of this section.

"The application of barnyard manure has shown marked value. Sod crops should not enter into short rotations. Neither fall nor spring plowing has a marked advantage of one over the other in the average of a series of years. Disking land upon which a crop of corn has been raised, and kept free from weeds, is as good a preparation for the succeeding grain crop as plowing."

Dry farming in Egypt, ALCHEVSKI (*Bul. Dir. Gén. Agr. Com. et Colon. Tunis, 18 (1914), No. 80, pp. 583-587*).—This article describes irrigation experiments conducted with wheat and barley in wooden tanks of 1 square meter surface and 1 cubic meter capacity. The amounts of water used ranged from 100 to 700 liters per tank.

In the case of the barley a constant yield was not reached. The yields of grain increased regularly with the increase in irrigation water and ranged from 23 to 247 gm. per tank. In the case of the wheat the constant weight was reached with the application of 600 liters of water per tank. The wheat yields ranged from 92 to 304 gm. of grain per tank. The maximum amount of water used reached 1 cubic meter per square meter of soil surface.

[Report on the progress of farm crops investigations] (*Missouri Sta. Bul. 131 (1915), pp. 475-477, 484-486, fig. 1*).—In experiments with cowpeas and soy beans by J. C. Hackleman it is noted that rows spaced from 30 to 36 in. apart gave the best seed production and that 60 lbs. of seed per acre gave the largest hay yield. Canada peas and oats gave the best mixture for spring forage

crops, and rape or Canada peas for a single crop. Sorghum showed best for a summer forage, and rye or rye and vetch for a fall crop. Crimson clover was not so satisfactory as vetch. In alfalfa experiments Northern seed is noted as being superior to commercial seed, especially that from subtropical and warm humid climates.

From results of 25 years of crop rotation experiments, in charge of M. F. Miller and C. A. Le Clair, it is stated that "a rotation alone even including legumes is not sufficient to maintain soil fertility providing all crops are removed. Rotation maintains productiveness very much better than continuous cropping of any kind. A rotation of corn, oats, wheat, clover, timothy, manured at the rate of seven tons annually maintains the productiveness of the soil and is also financially profitable. It was found profitable to apply manure to continuously cropped land. Continuous fertilizing with commercial fertilizers on continuous wheat at a rate sufficient to supply plant food for a 40-bu. crop annually maintains the productiveness as high as does the seven tons of manure annually. Continuous timothy with manure has been one of the most profitable treatments."

As results of studying the effect of various crop rotations on the physical character of the soil, by M. F. Miller and C. A. LeClair, it is noted that "the system of cropping does not influence the mechanical composition of the upper 4 ft. of soil. A system of rotation may influence the water retaining power of the surface soil by influencing the amount of organic matter present. The system of cropping apparently has no appreciable effect on the movements of air or water in the subsoil."

Experiments in the associated growth of corn and cowpeas have shown that "when cowpeas are grown with corn either between the rows or in the row, the nitrates of the soil are not greatly reduced below the amounts present when corn or cowpeas are grown alone. Cowpeas grown with corn does not seriously exhaust the soil moisture, although more water is used than in the case of corn alone. The average height of the corn plant is shortened about a foot when cowpeas are grown in the corn. The number of leaves on the corn plants grown with cowpeas is greater at the time of harvest than on the plants where corn is grown alone, but the yield of corn is slightly decreased when cowpeas are grown with corn."

It appears from data gathered in a study of the development of the maize plant, by J. C. Hackleman and A. R. Evans, "that the most important period in the growth of the corn plant, from the standpoint of soil moisture, is the period from the time the corn is usually 'laid by' until the ear is practically formed. There is a direct relation between the amount of moisture present in the soil and the amount of growth. Clay loam soil gives a larger root development than sandy loam. The growth of the vegetative part above the ground is not necessarily in proportion to the root growth."

"In a system of continuous wheat growing followed by cowpeas the same year [this experiment being conducted by C. A. LeClair], the effect of removing cowpeas from the land results in a gradual decrease in the wheat yield, according to data collected during a period of twelve years. Better results are secured when the cowpeas are disked in rather than when plowed under."

Growing field root, vegetable, and flower seeds in Canada, M. O. MALTE and W. T. MACOUN (*Canada Expt. Farms Bul.* 22, 2. ser. (1915), pp. 15).—This gives general suggestions as to methods of producing seeds of mangels, sugar beets, turnips, carrots, swede beets, parsnips, cabbage, cauliflower, onions, celery, and flowers.

Farm crops, C. A. ZAVITZ (*Ontario Dept. Agr. Bul.* 228 (1915), pp. 80, figs. 17).—This gives the results of tests, chiefly variety tests, of farm crops, includ-

ing cereals, legumes, root crops, and forage crops, and states the yields for varying periods of years for different classes of crops.

Work in the nurseries and distribution of plants, F. BIRKINSHAW (*Imp. Dept. Agr. West Indies, Rpt. Agr. Dept. St. Vincent, 1913-14, pp. 2-10*).—This briefly notes progress in manurial experiments with cotton, arrowroot, and cassava, breeding and selection experiments with cotton, and cultural trials of peanuts, sugar cane, and sweet potatoes.

[**Field experiments**], A. G. BIRT (*Ann. Rpt. Agr. Expts. Assam, 1914, pp. 7-27*).—This reports work continued from previous years at the Jorhat Experiment Station, covering variety tests of sugar cane and manurial tests with applications of air-slaked lime, ground limestone, wood ashes, and flour phosphate, and green manuring with cowpeas to rice and barley. The use of lime is noted as being essential for successful crops on the soils tested, and ground limestone showed a quick action that made it of value.

[**Field experiments**], B. C. BASU (*Ann. Rpt. Agr. Expts. Assam, 1914, pp. 32-49*).—This reports work for the year at the Upper Shillong Station.

In potato experiments cut seed showed an increased yield of from 3 to 4 per cent over whole seed tubers. In a test of seed rate it was found that 12 maunds (984 lbs.) per acre gave more satisfactory results than either 14 or 16 maunds. The yields ranged from 236 to 253 maunds per acre.

Rotation experiments, manurial experiments on peaty soils, and trials of new fodder and other plants are briefly noted as new work.

Growing forage crops for hogs, R. R. SNAPP (*West Virginia Sta. Circ. 19 (1915), pp. 4*).—This offers suggestions for the production and use of forage suited to West Virginia conditions and gives a table showing time of seeding and use of forage crops covering a 12-month period.

Native pasture grasses of the United States, D. GRIFFITHS, G. L. BIDWELL, and C. E. GOODRICH (*U. S. Dept. Agr. Bul. 201 (1915), pp. 52, pls. 9*).—This bulletin briefly comments upon the conditions which seem to make investigation of range forage plants a necessity, and discusses and describes 135 native grasses of the continental United States.

Chemical analyses, both original and compiled, as available, show the percentage of moisture, ash, ether extract, crude fiber, nitrogen-free extract, protein, and pentosans for each species, and it is noted that a sample of each has been preserved as a herbarium specimen.

Pasture problems: The response of individual species under manures, R. G. STAPLEDON (*Jour. Agr. Sci. [England], 6 (1914), No. 4, pp. 499-511*).—This article examines in detail the behavior of a few typical species of grasses under the action of manures and gives results of a study of the action of these species in relation to the types of grass land on which definite experiments have been carried out.

“The effect of manurial treatments has been gauged on meadows by comparing the weight of the produce from the several plats, on pastures by comparing the live weight increase of stock, or by comparing the milk yield of cattle fed upon the plats. Analyses have been made at several stations to show the action of manures on the botanical composition of the herbage on plats variously treated.”

The types of soils that were considered were calcareous soils over Great Oolite, residual clay over Oolite, good second-class pastures on Ordovician shales, and heath. Tabulated data are given regarding *Agrostis stolonifera*, *A. vulgaris*, *Festuca ovina*, *Dactylis glomerata*, *Lolium perenne*, *Bromus erectus*, and *Trifolium repens*.

In concluding it is noted that the factors which are always operative and which will tend to exaggerate or diminish the action of the manures are the

botanical composition of the herbage of the plats (before the manures are added) in relation to the type of grass land to which they belong, and the prevailing meteorological conditions. Factors which are indirectly dependent on the nature of the manures added are the rôle the manure exercises in merely disturbing the prevailing equilibrium, and the effect the treatment may have on the physical, chemical, and biological properties of the soil. Factors which are dependent on the chemical composition of the manures added are the individual appetites of the several species for the particular plant foods in the form they are added, and the physiologically depressing effect particular manures may produce on individual species.

A bibliography of 11 titles is included.

Experiment tanks for the determination of the water requirements of the principal meadow and pasture grasses. C. VON SEELHORST (*Jour. Landw.*, 62 (1914), No. 4, pp. 337-344, fig. 1).—This article describes concrete sunken tanks and methods employed for the determination of water requirements of grasses.

Grasses and clovers on the Murrumbidgee irrigation area.—A spring trial, R. W. McDIARMID (*Agr. Gaz. N. S. Wales*, 26 (1915), No. 2, pp. 127-129).—This article gives results of the first season's growth of spring sowings of the following grasses and clovers: Strawberry clover (*Trifolium fragiferum*), Chilian clover (*T. pratense perenne*), Egyptian clover (*T. alexandrinum*), white Dutch clover (*T. repens*), Rhodes grass (*Chloris gayana*), *Phalaris bulbosa*, Texas blue grass (*Poa arachnifera*), prairie grass (*Bromus unioloides*), perennial rye (*Lolium perenne*), tall fescue (*Festuca arundinacea*), Hungarian brome grass (*B. inermis*), cocksfoot (*Dactylis glomerata*), Sudan grass (*Andropogon sorghum*), and panic grasses (*Panicum flavidum* and *P. bulbosum*). Among these it is noted that Rhodes grass, Sudan grass, panic grass, Hungarian brome grass, and tall fescue were most successful. The clovers were unsuccessful.

Results of experiments on the manuring of grass carried out at Moorlands Farm, Kineton, Warwickshire. E. PARKE (*London*, 1913, pp. 3).—This article gives results of the twelfth season of experiments on the manuring of grass, carried out at Moorlands Farm, Kineton, with the cooperation of Dr. Bernard Dyer.

It is stated that in general "the unmanured land is still conspicuous for the poor, wiry nature of the grass and the abundance of plants which, in a pasture, may be regarded as weeds. On all the manured plats, on the other hand, there is an abundant growth of rich grass. Where phosphates, or phosphates and potash salts, have been continuously applied without nitrogen, the growth of plants of the clover kind is most conspicuous; while on the plats on which nitrate of soda has been continuously used without phosphates or potash (a mode of manuring which on general principles is not to be recommended), the grasses, as distinguished from clovers, are most prominent. The best herbage, however, in which clovers and grasses appear to flourish with equal vigor and luxuriance, is still found on the plats on which both phosphates and nitrate are used every year."

Universal hay tonnage table. MOLLIE D. CHESNUT (*Torrington, Wyo.: Author*, 1915, pp. 32).—Tables are given showing the number of tons of hay in a stack, according to the required measurement of round stacks, and based upon United States Government rules.

Western hay tonnage table. MOLLIE D. CHESNUT (*Author: 1914*, pp. 12).—A table showing the tonnage when width, overthrow, and length of stack are given for alfalfa and wild hay, with rules for computation.

Grain inspection in Canada. R. MAGILL (*Ottawa: Govt.*, 1914, pp. 64, figs. 34).—This describes and illustrates the methods of sampling, weighing, and testing grain in western Canada.

The peas and beans of Burma, E. THOMPSTONE and A. M. SAWYER (*Dept. Agr. Burma Bul. 12 (1914), pp. 107*).—This bulletin gives the results of an extended survey of the peas and beans of Burma covering almost four years, during which period several hundred samples of beans were examined. Aside from the botanical names and descriptions, the locality and local names of the plants are given. The genera studied include *Cajanus*, *Canavalia*, *Cicer*, *Crotalaria*, *Cyamopsis*, *Dolichos*, *Glycine*, *Lathyrus*, *Lens*, *Mucuna*, *Pachyrhizus*, *Phaseolus*, *Pisum*, *Psophocarpus*, *Sesbania*, *Vicia*, and *Vigna*.

Soy beans and cowpeas, T. A. KIESSELBACH (*Nebraska Sta. Bul. 150 (1915), pp. 31, figs. 7*).—This bulletin discusses the value of soy beans and cowpeas for Nebraska farmers, and gives general directions for their production as hay, grain, and silage crops and results of tests covering periods of varying lengths. The average yields of eight varieties of soy beans from 1909 to 1914 ranged from 13.39 to 15.87 bu. per acre for the different varieties. The average yields for all varieties for the different years ranged from 6.11 to 22.84 bu. per acre. A summary shows the comparative yields of corn, wheat, oats, and Haberlandt soy beans at the station to have been 42, 36.5, 49.5, and 16 bu. as a 6-year average.

Inoculating soy beans at the station, either by the culture or soil method, failed to increase the yield materially. The average yield of the four earliest varieties tested was 1 bu. more per acre when the rows were 28 in. apart than when 35 in., but these results were reversed for the four latest maturing varieties.

Soy beans in cooperative farmers' tests showed unsatisfactory results in general.

Soil physics and soil moisture in relation to first year's growth of alfalfa, L. R. MCNEELY and G. W. KABLE (*New Mexico Sta. Bul. 93 (1915), pp. 42, figs. 18*).—This gives the results as regards the growth of alfalfa in 1914 of various soil moisture and cultural conditions. Four classes of soils were used, viz. (1) 6 ft. or more of sandy loam, (2) 4 to 5 ft. of sandy loam over gravel, (3) 2 to 4 ft. of sandy loam over gravel, and (4) 2 ft. of sandy loam over gravel. Methods of surface treatment consisted in drilling alfalfa, planting in rows 30 in. apart, and fallowing. Irrigation treatments consisted in applying water in 2, 3, 4, and 5 in. depths at each application in such a way as to maintain about a 7 per cent moisture content.

The yields on the different classes of soil differed only slightly, ranging from 4,401 to 4,882 lbs. per acre under similar treatment. It was found that the deepest soils required the least water, 972, 1,051, 1,279, and 1,450 lbs. of water being required to make a pound of hay on the respective soil classes. It is stated that nearly the same amount of water was necessary to keep the soil moist where there was no crop as was used on the plats that were covered with plants, and that where the alfalfa grew in rows 30 in. apart more water was required than in either of the other cases.

The plats that were covered to a depth of 5 in. at each irrigation required an average of nearly 30 in. of water during the season; those covered to a depth of 2 in. required only 19 in., although the latter were irrigated a greater number of times than the former. The number of pounds of water required per pound of hay produced for different depths of irrigations were for 2 in., 1,026 lbs.; 3 in., 1,168 lbs.; 4 in., 1,180 lbs.; and 5 in., 1,377 lbs.

The number of pounds of water required to produce a pound of hay for different total depths of water during the season were found to be for 16.75 in., 1,023 lbs.; 23.08 in., 1,105 lbs.; 26.53 in., 1,235 lbs.; and 34.46 in., 1,613 lbs. For the different depths of irrigation, 2, 3, 4, and 5 in., the yields per acre and the yields per acre-inch of water were, respectively, 4,363 lbs., 235.8 lbs.; 4,559.9,

198.2; 4,707.5, 197.4; and 4,943.4, 177.7. The yields resulting from variation in total depths varied similarly to those from different depths at each irrigation.

The examination of the root systems showed that the plants had deeper roots on the shallow soil than on the deepest soil. The plants on the deepest soil plat receiving 5 in. of water had better developed root systems than those receiving 2 in. On the shallow soil there was little difference for the different depths of irrigation.

Effect of frequent cutting on the water requirement of alfalfa and its bearing on pasturage, L. J. BRIGGS and H. L. SHANTZ (*U. S. Dept. Agr. Bul. 228 (1915), pp. 6, figs. 2*).—This paper describes a pot experiment conducted as in those previously noted (*E. S. R.*, 29, p. 825), and gives the results obtained with Grimm alfalfa. Three cuttings were made of the plants of the A series of pots during the season, and the plants of the B series were also cut back weekly during the middle period, somewhat as in pasturage.

The results showed that "the water requirement of the two series during the first period (i. e., up to the time of the first cutting) was practically the same. The mean ratio of the six pots of series A (check) was 600 ± 17 and of series B 615 ± 6 . The difference is less than the probable error.

"During the second period the water requirement of the check series was 853 ± 13 , while the series which was cut weekly during this period gave a water requirement of 975 ± 23 , an increase of 14 ± 4 per cent. It thus appears that alfalfa is slightly less efficient in the use of water when subjected to weekly cuttings.

"During the third period, when both sets were again treated alike, the water requirement of the check series (A) was 421 ± 10 and that of series B 479 ± 16 . The B series thus shows during the third period also a slight increase (14 ± 4 per cent) in water requirement compared with series A."

It is noted that when the water requirement is based on the total dry matter produced during the season, series B was practically as efficient as the check series. The explanation seems to have been found in the relative yields during the second period, during which time series B produced only 18 per cent of its total dry matter, while the check series produced 38 per cent.

"The check series produced practically the same amount of dry matter during the second period as during the first. Series B produced only 30 per cent as much during the second period, the small plants being unable to elaborate plant material as rapidly as the larger plants of series A. Series B was also maintained during the midsummer period with an actual expenditure of only one-third the water required by the check series. This forced economy in the use of water through frequent cutting seems not to be without effect on subsequent production. Series B produced only 48 per cent as much dry matter during the third period as the check series, while during the first period, notwithstanding the shorter period of growth, series B produced 60 per cent as much dry matter as the check series."

The bearing of these results on the management of alfalfa lands is discussed to show a means of limiting the growth of the crop, so that its demand for water will not exceed the available moisture supply, by a system of pasturage in midsummer.

Barley in the Great Plains area: Relation of cultural methods to production, E. C. CHILCOTT, J. S. COLE, and W. W. BURR (*U. S. Dept. Agr. Bul. 222 (1915), pp. 32, figs. 2*).—The study of the yields obtained under various methods of seed-bed preparation as here presented is made in such a way as to show the effect of the crop immediately preceding and the tillage involved in preparing the seed bed for barley. The area included in these investigations covers parts of ten States and about 400,000 sq. miles of territory, and ranges

in altitude from 1,400 to 6,000 ft. Climatic conditions and the general plan of the investigations are described. Tables show the average cost per acre of the farm operations, the cost per acre of producing barley in the shock by the different methods, and the results at individual stations. The total cost of production of barley in the shock by the different methods of preparation is given at \$4.65 for disked corn land, \$5.45 for listed, \$5.99 for spring plowed, \$6.46 for fall plowed, \$7.07 for subsoiled, \$11.40 for summer tilled, and \$14.51 for green manured land.

The conclusions state that "differences in the climatic conditions of different seasons have caused much wider variations in yields than have resulted from differences in cultivation. Yields at Belle Fourche, Garden City, Dalhart, and Amarillo have been markedly lower than those obtained at the other field stations. The only profit shown at any of these stations is 35 cts. an acre on disked corn ground at Belle Fourche.

"The highest average yields at eleven of the fourteen stations have been by summer tillage. On the average, it increased the yields nearly one-half over those produced on land cropped in the preceding year. On account of its cost it has not been the most profitable method of production.

"At ten of the fourteen stations under study disked corn ground produced higher yields than from either the fall plowing or the spring plowing of barley stubble. It has been the most profitable method under trial at all the stations except Hettinger.

"The relative advantage of either fall or spring plowing is largely dependent upon the season. In the general average of the thirteen stations at which each method has been tried there is practically no difference. At only three stations has there been an average difference of over 2 bu. per acre between the two methods. At the four more southern stations fall plowing has been better than spring plowing.

"At the seven stations where subsoiling for barley has been tried it has produced an average of only 0.4 bu. more than fall plowing. At only two stations has there been a marked difference in the results of the two methods. At one of these, subsoiling has been responsible for an increase and at the other for a decrease in yield.

"At eight stations listing instead of plowing has been tried. While the resulting yields have not been materially different from those on fall-plowed land, the lower cost of listing has made it the more profitable method."

Field beans, a profitable West Virginia crop, I. S. Cook (*West Virginia Sta. Circ. 18 (1915), pp. 11, figs. 5*).—Methods of production and harvesting of field beans and the treatment of bean pests are given.

Hardier spineless cactus, D. GRIFFITHS (*Jour. Heredity, 6 (1915), No. 4, pp. 182-191, figs. 5*).—This article notes selections already made in three varieties, *Opuntia cacanapa*, *O. subarmata*, and *O. ellisiana*, which are described and illustrated, and which have been crossed with the more tender varieties of spineless cactus. The results are forms which are entirely devoid of spines and are as rapid of growth as the spiny natives of the Texas region.

Corn in the Great Plains area: Relation of cultural methods to production, E. C. CHILCOTT, J. S. COLE, and W. W. BURR (*U. S. Dept. Agr. Bul. 219 (1915), pp. 31, figs. 6*).—The area covered by these investigations is that noted for barley (see p. 230). The method of work adopted involved the raising of different crops in various combinations or systems of rotations and under different methods of cultivation.

In a study of the comparison of cultural methods it is shown that the average cost per acre of the farm operations involved in growing corn in the Great Plains area is as follows: Plowing, \$1.71; disking, 75 cts.; harrowing,

17 cts.; subsoiling, \$1.43; drilling, 40 cts.; cultivating, 38 cts.; listing, 60 cts.; cutting and binding, 62½ cts.; shocking, 50 cts.; twine, 22½ cts.; and binder wear and repair, 15 cts. The comparative cost per acre of producing corn by different methods is shown as listed, \$5.98; spring plowed, \$7.11; fall plowed, \$7.49; subsoiled, \$8.18; and summer tilled, \$12.36. Data for each station are given and the results discussed.

"No one method of seed-bed preparation is essential to the production of corn in the Great Plains. Differences in seed-bed preparation, other than summer tillage, have not produced wide differences in grain yields, except at Huntley, Mont. Summer tillage has slightly increased the grain yield at all except three stations and has materially increased the fodder yields at the three southern stations. The increase in yields, however, has not been sufficient to make it the most profitable method at any station except Scottsbluff.

"At some of the stations, especially at North Platte and Akron, crop sequence is more important than seed-bed preparation in the production of corn. At eight of the 13 stations corn as a grain crop has not been produced at a profit by any method. When a value of \$4 per ton is assigned to the stover or fodder, corn has been profitably grown by some method at all but one of the stations. The response to differences in culture and crop sequence is greater in the southern and central portion of the Great Plains than it is in the northern portion."

A new and prolific variety of cotton, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 26 (1915), pp. 7, fig. 1*).—This notes a variety of cotton produced by the station having a long, fine staple, very prolific, remarkably wilt resistant, adapted to upland conditions, and bred from Sea Island, Russell Big Boll, Jacksons Wilt Resistant, and Simpkins Prolific. Cultural methods are suggested.

[Flax growing], H. L. BOLLEY (*North Dakota Sta. Circ. 6 (1915), pp. 4*).—This suggests improved methods, including early sowing, the preparation of corn ground for seeding to flax, the use of wilt-resistant varieties, and the official inspection of the seed field by the station.

Fiber flax, F. C. MILES (*U. S. Dept. Agr. Farmers' Bul. 669 (1915), pp. 19, figs. 10*).—This discusses the production of flax for fiber, covering methods of cultivation and preparation of the fiber.

Oats in the Great Plains area: Relation of cultural methods to production, E. C. CHILCOTT, J. S. COLE, and W. W. BURR (*U. S. Dept. Agr. Bul. 218 (1915), pp. 42, figs. 2*).—This bulletin contains a study of the yields of oats from different methods of cultivation and seed-bed preparation similar to that for barley (see p. 230). Descriptions of the climatic conditions and of the general plan of the investigations are followed by the results obtained at each of the several stations.

The average cost per acre of the farm operations involved is given as the same as that for oats (see p. 231), except that cutting and binding cost 40 cts., shocking 13 cts., and twine 25 cts. The cost per acre of producing oats in the shock in the Great Plains area, as the averages of data from eight stations, show for disked corn land \$4.50, listed \$5.30, spring plowed \$5.84, fall plowed \$6.31, subsoiled \$6.92, summer tilled \$11.25, and green manuring \$14.36.

Tables show itemized data for yields and costs at each station for the different methods for several years, and these are briefly discussed.

These investigations have shown that "the relatively poor adaptation of oats to the southern section of the Great Plains can not be overcome by cultivation. Seasonal conditions cause much wider variations in yields than can be caused by differences in cultivation. . . ."

"At all stations where it has been tried, listing for oats has been either more profitable or has resulted in less loss than fall plowing. Green manuring has been productive of higher yields than either fall or spring plowing, or disking corn ground, at nine of the thirteen stations from which results by it are reported. The cost of production by this method was so high that it showed a profit at only two stations. Oats following summer tillage produced the highest average yields at all stations except Hettinger, where the yield was exceeded only by that on disked corn ground. While the expense of the method has prevented its being the most profitable, the degree of insurance which it affords against failure of the feed crop might justify its practice in oat production in at least some sections of the Great Plains. Disking corn ground yielded the highest profits of any method tested at all stations except Garden City and Dalhart. At these two stations the crop was produced at a loss, but this loss was less than by any other method."

Potato breeding and selection, W. STUART (*U. S. Dept. Agr. Bul. 195 (1915)*, pp. 35, pls. 16, figs. 2).—In this bulletin the author defines breeding and selection and their limitations in work with the potato, notes the technique in handling the pistil and stamens, discusses pollen-producing varieties, and gives results of experimental crosses since 1909.

It is noted as doubtful whether the secretion of a stigmatic fluid is a normal function of the potato blossom at the present time. This observation is stated as being contrary to the teachings of previous investigators. Records show the parentage, number of flowers crossed, number of seed balls developed, percentage of success, and the number of seedlings that produced tubers for over 100 crosses made in 1909. Varietal affinity is noted as a factor in making successful crosses. The method of growing and testing some 28,000 seedlings is described.

In regard to inheritance in the F_1 generation it is stated that "in a population of 1,425 seedlings from a cross between Irish Cobbler and Irish Seedling, the first parent having a creamy white skin and purplish tinged sprouts and the latter with flesh-tinted skin and purplish sprouts, color was absent in 70.2 per cent of the tubers. Of those showing color, 36 were mottled with white, 229 were flesh, 104 were red, 55 were purple, and one was violet-black. In another instance, out of a population of 870 seedlings of Irish Cobbler crossed with Keeper, color was absent in 69.7 per cent of the tubers. The pollen parent, Keeper, being a red-skinned variety, it would seem that if white were recessive a larger proportion of the F_1 generation should have shown color."

The work of Goodrich and other early breeders in the improvement of the potato by selection are briefly discussed and the tuber-unit and hill-selection methods described.

It is stated that the almost total failure of our present-day commercial varieties to produce seed balls is due to male sterility rather than to imperfect pistils or ovaries, and that the tuber-unit and hill-selection methods are chiefly valuable in pointing out the weak, unproductive, and diseased seed tubers.

Report of the officer in charge of the Prickly Pear Experimental Station, Dulacca, J. WHITE (*Ann. Rpt. Dept. Pub. Lands Queensland, 1913*, pp. 66-78, pls. 3).—This gives in detail the methods employed in searching for ways and means for the destruction of the prickly pear in Queensland. The effects of different poisons applied by injections and by spraying, treating with poisonous gases and vapors, and the use of parasitic insects are described.

The prickly pear problem in Australia, C. F. JURITZ (*Reprint from Weekly Cape Times and Farmers' Rec., 1915, Feb. 5*, pp. 14, figs. 6).—This article gives compiled results from various sources of methods for the eradication or utiliza-

tion of prickly pear in Australia. The methods consist in the introduction of the cochineal insect, poisoning the plants with various chemicals, and establishing a commercial use for the plant, such as a source of potash fertilizer, oil, industrial alcohol, and fodder for stock.

Some observations on Upper Burma paddy (grown under irrigation), E. THOMPSTONE (*Agr. Jour. India*, 10 (1915), No. 1, pp. 26-53, figs. 11).—This article notes the improvement of rice by selection and crossing as to the number of grains per plant, variation in weight of grain, and tillering.

It is shown that as the tillers increase there is an increase in the weight of grain, but this increase is not in direct proportion to the number of tillers produced by the plant. As the number of tillers increase the average yield per tiller decreases.

In cross-fertilization it was found that "whiteness and redness of glumes act as a pair of simple Mendelian characters, the former being dominant. Whiteness and redness of grain also act as a pair of simple Mendelian characters, redness being dominant."

It is noted that "as the heads of paddy emerge from the sheath the flowers mature from above downward, before or when very little spreading of the panicle has taken place. The stamens emerge daily generally from the segment of the head which has just come out of the sheath, and the head ripens the whole of its flowers in three or four stages on successive mornings. The glumes open, the stamens hang out, and the feathery stigmas protrude once only and for a short time in the early morning, usually between 7 and 10 a. m. Dewy mornings appear to be most favorable, and 'flowering' will then be at its maximum height about 8 to 9 a. m. As the dew gradually disappears the flowers will be found to be opening rapidly but, as soon as the day begins to get very bright, dry, and warm, no more glumes open and those already opened close up again, the stamens by this time being dried and shriveled up.

"The angle formed by the two edges of the glumes when the flowers are fully open is about 25 to 30°, but the stamens have often emerged before the flower is fully open. Pollination takes place before the glumes open, or at the moment of opening, seldom afterwards. At the moment they emerge from the glumes the anthers are found to be already open at the lower end, and with the aid of a microscope pollen grains can generally be found on the stigmas."

The transplanting of [rice], N. S. MCGOWAN (*Ann. Rpt. Agr. Stas. Bihar and Orissa*, 1913-14, pp. 20-23).—This article gives the results in transplanting 1, 2, 4, and 6 seedlings to a hill under varying conditions.

The data show that 4 seedlings per hill gave the largest yields in general, whether planted in a wet or dry seed bed. Using 8 maunds (about 650 lbs.) of seed per acre gave better results in the seed bed than 1, 4, or 16 maunds. Transplanting 18 in. apart seemed preferable to 6, 9, or 12 in. With heavy applications of barnyard manure (160 tons per acre) the single plant hill equaled or exceeded the others (2, 4, and 6) in yield.

Notes on the hydrocyanic acid content of sorghum, J. J. WILLAMAN and R. M. WEST (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 2, pp. 179-185, figs. 2).—The following conclusions were drawn from tests at the Minnesota Experiment Station with two varieties, feterita and Orange sorgho, grown on different soils and under varying fertilizer treatments:

"When sorghum is grown on poor, infertile soil, added nitrogen may slightly increase the amount of hydrocyanic acid in the plant. With a fertile soil and abundant nitrogen this effect may not be produced. During the first three or four weeks of the plant's life the prussic acid is concentrated in the stalks. Then it rapidly decreases and disappears there, but apparently persists in the leaves in decreasing percentages until maturity.

"Climate and variety may be more important factors than soil nitrogen in determining the amount of the acid in the plant. Complete hydrolysis of the glucosid is obtained by digesting the macerated tissue for two hours at 40 to 45° C."

Soy beans, an important West Virginia crop, I. S. COOK and W. B. KEMP (*West Virginia Sta. Circ. 20 (1915), pp. 19, figs. 4*).—Methods of utilizing soy beans as a seed crop, hay, silage, pasture, and soil improvement crop are briefly noted. Two, 3, and 4 year rotations that include soy beans are suggested. Thirty-three varieties are described and yields from some of them for 1912, 1913, and 1914 are given that show a range up to 25.3 bu. of seed per acre. Of the varieties tested, Wilson, Roosevelt, and Peking are noted as the most promising sorts for West Virginia. Cultural and harvesting directions are given.

Saccharose formation in the sugar beet, II. COLIN (*Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 20, pp. 687-689*).—This gives the results of a study to determine whether the saccharose is developed in the leaf and passes to the roots as such or whether it passes to the roots as invert sugar and is there transformed to saccharose. From the use of two varieties of beet studied in light and in darkness the author concludes that both of these phenomena take place, with much variation in different varieties of beets.

Sweet potato [experiments], F. WATTS (*Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. [etc.], Antigua, 1913-14, pp. 5-8*).—In variety tests of sweet potatoes covering the period from 1901 to 1914, inclusive, the average yields ranged from 31 to 51 lbs. per plat of $\frac{1}{16\bar{6}}$ acre for 16 varieties.

In plant selection experiments based on large yield per plant it is noted that very satisfactory results are being obtained. "The first year plants yielded from 3 to 6 lbs. each, which increased to from 4 to 17½ lbs. the second year.

The early agricultural history of timothy, C. V. PIPER and KATHERINE S. BORR (*Jour. Amer. Soc. Agron., 7 (1915), No. 1, pp. 1-14*).—This article notes the early agricultural history of timothy or herd's grass as first discovered in New Hampshire in 1700 or in Maryland in 1720. A bibliography of works published prior to 1847, in which this grass is mentioned, is cited.

A text-book on tobacco, C. WERNER (*New York: Tobacco Leaf Publishing Co., 1914, pp. 323, figs. 34*).—An enlarged edition of this work (E. S. R., 22, p. 637).

Relation between the dry matter and winter resistance of different varieties of winter wheat, E. SINZ (*Jour. Landw., 62 (1914), No. 4, pp. 301-335*).—This gives the results of experiments carried on at Göttingen in 1911 and 1912 in the experiment field, in pots, and in sunken masonry tanks with 10 varieties of wheat.

It is shown that there is a direct relation between dry matter and frost resistance; that is, a high, dry matter content correlates with high frost resistance, and vice versa. Those varieties that show ability to prevent rapid transpiration by the firm texture of the tissues and by the action of the stomata were found to be among those that were most highly frost resistant.

Hard-wheats winning their way, M. A. CARLETON (*U. S. Dept. Agr. Yearbook 1914, pp. 391-420, pls. 7, figs. 4*).—This article traces the evolution of the hard wheats in this country from their introduction from Russia through the stages of increased production on the Great Plains, and the milling and commercial developments as to their products.

HORTICULTURE.

[Progress report on horticultural investigations] (*Missouri Sta. Bul. 131 (1915), pp. 479-483, fig. 1*).—This comprises concise statements of progress made along various lines of horticultural work during the year ended June 30, 1914.

In a study of bud selection for increasing yields by J. C. Whitten it has been found that continuous bud selection of strawberry plants during a period of 15 years has given no gain in the total productiveness of the plats originated from high-productive plants over the plats originated from the low-productive plants. Selection from bud-propagated strawberry plants does not appear to have limited the range of variation among individual plants. A similar experiment has been conducted with scions selected from an exceptionally poor-yielding Ben Davis apple tree and from the Ben Davis tree which produced the largest and best apples of its kind on the station grounds. Examination of the third year's crop showed no perceptible difference in size, color, grade, or quality of the fruit from the two lots of trees. The total product from the trees in each lot averaged slightly higher than those propagated from the high-producing parent. There appeared to be as much variation between individual trees in either plat as between the two.

An investigation is being made by C. C. Wiggins of the tendency of certain varieties of fruit trees to bear only in alternate years, as compared with varieties which tend to bear more regularly. Observations made in the spring in the case of a Gano apple tree showed that there were no blossoms produced on spurs which had borne fruit the previous year. Likewise but very few blossoms were produced on the Rome and Jonathan trees on bearing spurs of the previous year.

The test at the station of fall *v.* spring planting of trees, by J. C. Whitten, has shown that fall-planted trees have reached their bearing habit approximately one year in advance of the spring-planted trees. In every case the fall-planted trees have grown much better during the year than those planted in the spring. This was particularly true of cherries. In apples the fall-planted trees showed a greater growth of from 33½ per cent to 150 per cent in excess of spring-planted trees. Fall-planted trees produced a thicker trunk and the growth of the lateral buds was more vigorous.

Observation of the self-fertility and self-sterility of fruits by C. C. Wiggins during the last year indicates that all the varieties of peaches commercially grown in Missouri are self-fertile, and that mixed plantings for the sake of cross pollination are unnecessary. Only a few of the commercial apples gave indications of being able to fertilize themselves.

In the orchard nutrition studies by J. C. Whitten and C. C. Wiggins the peach is the only fruit which has so far shown any advantage from the application of fertilizers (E. S. R., 31, p. 335). On all plats fertilized with nitrogen, whether alone or in combination, the number of peaches set was larger than on the other fertilized plats or on the check plats, and the average increase in the number of peaches produced was 50 per cent. The average weight of the peaches fertilized with nitrogen, however, was only 60 per cent of the average weight of the peaches grown on plats receiving fertilizer other than nitrogen. The nitrogen-fertilized trees carried a very heavy foilage, and it is believed that extreme drought conditions caused an excessive evaporation from these trees.

Observations thus far made by C. C. Wiggins relative to the possibility of forecasting bloom by examination of fruit buds during the winter indicate that a fairly accurate prediction can be drawn from a count of the winter buds. This work is to be continued.

Division of horticulture.—Summary of results, 1914, W. T. MACOUN ET AL. (*Canada Expt. Farms Bul.* 82 (1915), pp. 88).—This comprises a summary of results secured in 1914 in the breeding and cultural experiments with fruits, vegetables, forest and ornamental trees, and herbaceous plants conducted at the

Central Farm, Ottawa, and at the various branch experimental farms and stations in Canada. The details of the work are to appear as usual in the annual report at a later date.

Among the commercial varieties of apples tested at the Central Farm Red June, Stayman Winesap, and Rome Beauty give considerable promise, both with reference to hardiness and quality, although it is believed that Rome Beauty should be tested further before recommending it for commercial planting in a climate as cold as that at Ottawa. The Delicious kills back and is not considered hardy enough for commercial purposes in that region.

Additional data are given on the closely planted Wealthy apple orchard (E. S. R., 32, p. 437). The estimated net profit per acre in 1914 was \$115.40, the average net profit per acre from date of planting, 1896, being \$90.49. Of the original 144 trees there are now 88 left.

In previous observations made for a number of years relative to the yields of individual trees of the same varieties of apples there was found to be a great difference in the yields from different trees (E. S. R., 27, p. 343). An experiment in scion selection was started in 1905 in which scions taken from the least productive tree, the most productive tree, and the tree which bore a good crop every year in a row of 18 Wealthy apple trees were root grafted and planted out in 1909 on a uniform piece of soil. The yields for the three bearing years 1912 to 1914 indicate that the bearing habit of the parent tree has been perpetuated in each case, although observations are to be made for several years before definite conclusions are drawn.

Of the autumn bearing strawberries being tested, the Progressive has thus far given the best results. In 1914 this variety yielded a fair crop of fruit in the regular season and also in the autumn, the fruit continuing to ripen until injured by frost. The results for the first season of a test of European grapes grown under glass are given. Data are also given on a series of experiments with orchard heaters conducted at the farm in the fall. The data secured indicate that these heaters may prove very useful in strawberry and truck crop plantations, where the value of the crop is relatively high. The usual notes are given on the more promising varieties of vegetables and ornamentals tested both at the Central Farm and at the branch stations. Fertilizer tests with potatoes are reported from the Fredericton, New Brunswick, substation, and cultural tests from the Rosthern, Saskatchewan, substation.

A series of tests was started in 1913 at the Kentville station, W. S. Blair in charge, to determine the advisability of fertilizing fruit trees when they are planted. The results to date indicate that there is little advantage in using fertilizers at planting time and that good cultivation is of greater importance. From two years' work carried on by this station in a number of cooperative orchards, it appears that four thorough applications of lime-sulphur arsenate of 1.00S sp. gr. will control scab as effectively as Bordeaux mixture without danger of russetting the fruit, which is usually more or less serious when Bordeaux is applied after the blossoms fall. The application of a dormant spray in addition to the regular sprays appears to be of little value in controlling scab. A test was made of the claim that sugar added to Bordeaux will prevent russetting. The addition of 2, 4, and 6 lbs. of sugar, respectively, to 4:4:40 Bordeaux arsenate mixture proved to be of no value as a preventive of russetting. A series of tests undertaken to determine the actual gain from arsenate of lead in lime-sulphur for the control of scab indicated that the arsenate of lead had very little fungicidal value. Commercial concentrate lime-sulphur appeared as effective in controlling scab as the home-boiled concentrate.

The university farm garden, A. L. DACY (*West Virginia Sta. Circ. 17 (1915)*, pp. 16, figs. 4).—The author here presents detailed records of demonstration

experiments in vegetable gardening conducted in the university farm garden during 1913 and 1914. The data given for each vegetable show the dates of planting, area planted, date of first sale, approximate yield, approximate average price, total sales, and estimated gross returns per acre. The results are further discussed from the standpoints of yields, distribution of income, relative values of the different crops, and the relative values of the different systems of cropping. This circular also contains a planting table for vegetables, together with a table showing the details of succession and companion cropping plans as used in 1914.

Cabbage, cauliflower, turnip, rape, and other crucifers, W. P. BROOKS (*Massachusetts Sta. Circ. 49 (1915), pp. 4*).—This is a revision of Circular 38 of the same series (E. S. R., 32, p. 337).

How to grow muskmelons, J. W. LLOYD (*Illinois Sta. Circ. 139, 2. ed., rev. (1915), pp. 18, figs. 8*).—The present edition of this circular (E. S. R., 23, p. 42) has been somewhat revised to conform to more recent information on the subject.

Arboriculture in Spain, J. M. PRIEGO (*Bol. Agr. Téc. y Econ., 6 (1914), Nos. 66, pp. 530-533; 67, pp. 626-633; 68, pp. 712-723; 69, pp. 827-833; 70, pp. 927-933; 71, pp. 1011-1017; 72, pp. 1115-1120*).—An analysis of fruit growing in Spain by groups and regions, with a discussion of the part to be played by the producer, the merchant, and the State with reference to the best future development of the industry.

Annual report on the Fruit Experiment Station, Shillong, for the year ending June 30, 1914, C. H. HOLDER (*Ann. Rpt. Agr. Expts. Assam, 1914, pp. 55-73, pl. 1*).—This comprises a brief descriptive account of the fruit station, which was started in 1912, together with a statement of the number and varieties of trees, bushes, and plants in the fruit plantations.

[**Final reports of the Royal Commission on the Fruit Industry**] (*Melbourne, Australia: Govt., 1914, pp. 23+19*).—This embraces the salient features of the majority and minority reports of a parliamentary investigation relative to the production, distribution, marketing, and exportation of Australian fruit, including the operations of producers, shippers, carriers, dealers, and others connected with the fruit industry. Recommendations looking to the betterment of the industry are also included.

New or noteworthy fruits, III, U. P. HEDRICK (*New York State Sta. Bul. 403 (1915), pp. 211-220, pls. 4*).—In continuation of a previous bulletin (E. S. R., 31, p. 337) the author describes the best recent fruit introductions as tested on the station grounds. Attention is called to the fact that these varieties are still on probation at the station and growers are advised to go slow in making commercial plantings of such fruits.

The varieties here described include the Niagara peach, Muscat Hamburg grape, Lambert cherry, Late Muscatelle plum, Industry gooseberry, Black Pearl black raspberry, Marlton red raspberry, and Amanda strawberry.

Experimental results in young orchards in Pennsylvania, J. P. STEWART (*Pennsylvania Sta. Bul. 134 (1915), pp. 20, figs. 4*).—The station started an extensive series of orchard experiments in various parts of Pennsylvania in 1907-8. The results of some of these experiments, especially those on the fertilization of mature orchards, have been reported on from time to time (E. S. R., 29, p. 437). This bulletin gives the results of various experiments which have been conducted in young orchards during the first seven years.

A comparative test was made of apple trees propagated on whole roots, on top pieces, and on bottom piece roots. As measured by the average size and height of trees after a period of 11 years in the orchard, it is concluded that there is practically no difference in efficiency between the various methods of

propagation now generally used in nurseries. The author calls attention, however, to the desirability of eliminating the seedling root entirely with the view of doing away with the numerous ill effects of poor unions and the development of definite and standard root systems, with which the injuries from root aphids and kindred difficulties might be reduced or entirely eliminated. Further work is planned along this line.

A test was made relative to the influence of scion selection in improving yields. The scions from supposedly superior individual trees were top grafted chiefly on Northern Spy stock and ordinary nursery trees of the same varieties were planted alongside for comparison. The relative yields from the two classes of trees as shown for eight varieties for the seventh year of growth are not sufficiently decisive, either to approve or condemn the practice of scion selection. The results as a whole thus far do not warrant anyone in paying materially higher prices for so-called pedigreed trees.

Another experiment is being conducted to determine the best stocks for use in top grafting. The Jonathan, Tompkins King, and Grimes apples were all top grafted on Northern Spy, Tolman, Wolf River, Paragon, and Champion stocks and compared with nursery-grown trees of these three varieties grafted on seedling roots. In all cases, except one, those of varieties top grafted on Wolf River, the top-grafted trees on known stocks have made a better average growth during the period, 1908 to 1914, than those grafted on seedling roots in the nursery. Among the various stocks the trees developed on the Paragon are now distinctly in the lead, with those on Tolman coming second. The superiority of these two stocks for Grimes and Tompkins King is very marked so far as growth is concerned. In smoothness of unions the Tolman and Champion are probably best, with Paragon next, except with grafts of the Jonathan, with which variety the Paragon stock has tended to outgrow the scions. Northern Spy stock has averaged third in growth and is about equal to Paragon in unions. Although making an excellent trunk and root system, it is considered less desirable than either Tolman or Paragon for stock purposes owing to its unusual tardiness in starting growth in the spring. Attention is called to some interesting relations between certain stocks and scions observed by S. Fraser, of Geneseo, N. Y. This nurseryman finds that the Twenty-Ounce top grafted on Baldwin makes from 50 to 100 per cent better trees in five to eight years than when worked on Northern Spy. The Wealthy does very poorly on Rhode Island Greening, whereas Rhode Island Greening does very well on Wealthy. Hubbardston scions top grafted on Ben Davis, Northern Spy, and Tolman resulted in such peculiar changes in twig color that they could not be used with safety for further scion wood until they had proved their identity by coming into bearing.

Four experiments in dynamiting orchard soils were started in 1912. Two of these were on orchards just being planted and two on 25-year-old Baldwin trees which had become more or less sod bound. Briefly stated the results for a period of three years have failed to show any appreciable benefits, either in the young or the old orchards.

In one experiment started in 1908 the orchard was divided into 45-tree plats, each involving three varieties of trees. The following treatments have been followed annually: Tillage, tillage and intercrop, tillage and cover crop, cover crop and manure, cover crop and fertilizer, mulch, mulch and manure, and mulch and fertilizer. Data secured on moisture, growth, and yield at the close of a 7-year period show practically no difference between the clean tillage plat and the plat tilled early in the season and sown to an annual cover crop of a mixture of red and crimson clover. The use of a tilled annual intercrop early

in the season followed by a late cover crop of rye resulted in nearly 12.5 per cent more tree growth than for trees under either tillage or tillage with a cover crop. In general all of the mulching methods gave better results than the tillage methods. The author concludes relative to this test that the best soil management in a young orchard is the one which conserves the moisture best. This gives the largest growth and earliest fruiting under most conditions. The moisture is conserved most efficiently by a good mulch of strawy manure or other plant materials, which should be accompanied by proper protection against mice. Where sufficient mulching materials are not available proper tillage and cover crops should give satisfactory results. On good tillable soil and with the trees well mulched the use of tilled intercrops is the most practical method of orchard development. The financial returns from intercrops of potatoes in these experiments have usually run from \$40 to \$50 an acre even on the very poor soil involved.

Among the annual cover crops buckwheat, hairy vetch, and millet rank high. It is suggested that the buckwheat may be harvested by high cutting or heading probably without materially reducing its favorable influences on the adjacent trees. The use of alfalfa in the orchard not only furnished an abundant supply of mulching material around the young trees, but under favorable conditions it may also afford a considerable surplus for hay. The mulch should be heavy enough to prevent the alfalfa from growing in competition with the principal tree roots. This system of management gave better results than any kind of annual tillage during the first seven years. In the older bearing orchards, where the mulch-producing area is small, three courses are suggested—mulching materials may be brought in, a tillage system, preferably by disking, may be adopted, or it may be possible to replace both by a proper system of fertilization.

The fertilizer experiments as a whole have shown that the fertility needs are often most important in the older orchards (E. S. R., 29, p. 437). In lieu of specific information relative to the needs of such orchards annual applications of either stable manure at the rate of 6 or 8 tons per acre or a commercial fertilizer carrying about 6 per cent nitrogen, 8 per cent phosphoric acid, and 4 per cent potash at the rate of about 500 lbs. per acre are recommended. On young trees applications of plant food alone have given as a rule but little benefit except in the presence of an abundance of moisture. In a few cases some actual injury has apparently resulted to young trees from rather heavy applications of commercial materials especially rich in the more soluble forms of potash. Hence a good mulch of manure is believed the best general application for young trees. Where this is not available moderate surface applications of the above noted general fertilizer are recommended.

Making old orchards profitable, L. GREENE (*Iowa Sta. Circ. 20 (1915), pp. 3-32, figs. 14*).—This circular summarizes the principal results secured in an apple orchard survey of Mills County, Iowa (E. S. R., 32, p. 540).

Stock influence upon the vintage quality and other characters of apples, B. T. P. BARKER (*Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 97-102*).—The results of analyses made under the direction of the National Fruit and Cider Institute for a number of years lead to the conclusion that the influence of the intermediate stock on the vintage quality is very slight, if it exists at all. Analytic data on fruit juice from various trees in 1913 with average data for the period 1908-1913 are given.

The cacao tree in the State of Bahia, L. ZEHNTNER (*Le Cacaoyer dans l'Etat de Bahia. Berlin: R. Friedländer & Sohn, 1914, pp. XII+156, pls. 49*).—An account of cacao culture in Bahia, based upon travel studies made by the author

during 1909 and 1911. The region of cacao culture is briefly described and consideration is given to the establishment of plantations, management, production, financial returns, varieties, harvesting and preparation, statistics, diseases and insect pests, transportation, and the relation of the State to the cacao industry.

• **Citrus fertilization experiments in Porto Rico**, C. F. KINMAN (*Porto Rico Sta. Bul.* 18 (1915), pp. 33, pls. 2, figs. 2).—This bulletin reports cooperative fertilizer experiments in citrus groves which were started in 1905 by H. C. Henriksen, continued by M. J. Iorns, and completed by the author. In order to determine the comparative effects of nitrogen, phosphoric acid, and potash, both complete and incomplete mixtures of these elements secured from various sources were applied. The results secured in three different groves are here presented in tabular form and discussed.

The results of the work as a whole show a pronounced effect on both trees and quantity of fruit due to fertilization. This effect was greatest as to trunk, top, and leaf growth, and as to leaf color where a complete fertilizer was given. The difference in leaf color appeared to be most pronounced during periods of drought. In one grove the color was poorest in the plat given no phosphoric acid and in another grove the color was poorest where no nitrogen was given.

The growth in the check plats was so slow and unsatisfactory that all except one were discontinued before the conclusion of the experiments. The appearance and growth of the trees in plats given a complete fertilizer were practically the same, except that in a plat given nitrogen in the form of dried blood they were not so thrifty. The weight of fruit harvested from check plats was only 27 per cent of that harvested from complete fertilizer plats.

In one grove the gain in yield by plats given three elements over those given two was 80 per cent and in the other 44 per cent. Of the trees receiving only two elements those given no potash bore more than those given no phosphoric acid.

The trees receiving no nitrogen gave the poorest yields. The average weight of the fruit per hundred was heavier in the plats given no nitrogen than in those where phosphoric acid or potash was omitted. The differences in yield between plats receiving muriate of potash and sulphate of potash were too slight to indicate the superiority of one form over the other. No differences were noted between these plats in respect to quality, flavor, or color of the fruit. In one grove where nitrogen was applied in the form of nitrate of soda the yield was but 83.7 per cent of that where an equal amount of nitrogen was given in the form of sulphate of ammonia. In another grove, however, there was practically no difference resulting from the two treatments. On the basis of the results of these experiments dried blood appears to be a somewhat less favorable source of nitrogen for citrus fruits than either sulphate of ammonia or nitrate of soda. No marked difference in flavor of fruit was observed resulting from the application of different fertilizers. There was also no apparent difference in time of ripening of the fruit between the various fertilized plats. The fruit ripened earlier in the check plat than in the fertilized plats.

• **Drug plants under cultivation**, W. W. STOCKBERGER (*U. S. Dept. Agr., Farmers' Bul.* 663 (1915), pp. 39, figs. 8).—The author calls attention to a number of drug plants suitable for cultivation in the United States and gives general suggestions relative to the culture, harvesting, distillation, yielding, marketing, and commercial prospects for drug plants. Specific information secured from various sources in this department is then given relative to the cultivation, handling, and yield of individual species, including also available data relative to the demand and prices paid.

A bibliography of department publications dealing with drug plants is appended.

Experiments in hybridizing Japanese flowers which appear to show a variation in Mendel's law, W. P. JENNY (*Sci. Amer. Sup.*, 79 (1915), No. 2036, pp. 18, 19; *abs. in Sci. Amer.*, 112 (1915), No. 8, p. 182).—The author found that the dry pollen of the white moonflower applied to the stigma is inert, and will not fertilize the ovary unless the pollen be wet with the fluid excreted upon the surface of the stigma of the moonflower. This discovery led to the series of experiments here described, in which the Japanese morning-glory was crossed with the white moonflower. As a result of these experiments, extending over several years, it is concluded that hybrids of Japanese morning-glory with the white moonflower are subject to Mendel's law in only a limited way, if at all. This is believed to be due to the influence of the fluid excreted by the stigma of the moonflower. Crosses between the Japanese and American morning-glories arising from pollination by insects follow Mendel's law.

Dwarf evergreens, G. V. NASH (*Jour. N. Y. Bot. Gard.*, 16 (1915), No. 183, pp. 47-61, pls. 2).—The author briefly discusses the selection and care of evergreens, and gives short descriptions of a number of dwarf evergreens, both coniferous and broad-leaved, which may be readily procured. Lists of evergreens for special purposes or conditions are also given.

Lime and sulphur solutions, G. E. STONE (*Massachusetts Sta. Circ.* 53 (1915), pp. 2).—This is a revision of Circular 39 of the same series (E. S. R., 32, p. 338).

FORESTRY.

The National Forests and the farmer, H. S. GRAVES (*U. S. Dept. Agr. Yearbook 1914*, pp. 65-88, pls. 6).—In this paper the author calls attention to many ways in which the National Forests influence the welfare and development of agricultural communities. Among the special benefits to the farmer here discussed are the benefits through protection of water resources, through supplies of forest products, from grazing privileges, direct and indirect benefits from the establishment and maintenance of various industries utilizing the resources of the forests, and the benefits from public improvements built by the Government.

The farm woodlot problem, H. A. SMITH (*U. S. Dept. Agr. Yearbook 1914*, pp. 439-456, pls. 8).—An economic discussion of the farm woodlot problem in which consideration is given to the question of taxes, woodlots as sources of wealth, marketing difficulties, how the farmer may protect himself in marketing timber, and woodlot values, present and future.

The new Massachusetts forest taxation law, F. W. RANE (*Boston: State [1915]*, pp. 35, pls. 8).—This pamphlet contains the full text, with explanation, of the Massachusetts forest taxation law passed in the spring of 1914.

Natural reforestation in the mountains of northern Idaho, H. B. HUMPHREY and J. E. WEAVER (*Plant World*, 18 (1915), No. 2, pp. 31-47, figs. 9).—The authors here present the results of a study of various types of natural reforestation as observed in the mountains of northern Idaho.

[Report of progress on] forestry (*Missouri Sta. Bul.* 131 (1915), pp. 478, 479).—A concise statement of progress made in forest investigations, carried on by E. C. Pegg during the year ended June 30, 1914.

With the view of studying the methods of prolonging the service of wood fence posts about 550 posts, representing 25 species, were set in 1913. Examination at the end of the first year showed no evidence of decay or fungus growth. Persimmon, honey locust, and a few coffee-bean posts showed damage

by borers. The creosote had leached out and discolored the soil to certain extent around some of the cottonwood, willow, and sycamore posts.

A test of the effect of storage conditions on the vitality of forest tree seeds indicates that the vitality is low after they have been stored for two years, and that the proper method of storing forest tree seeds will depend upon the species to which any particular seed may belong.

The preservation of structural timber, H. F. WEISS (*New York and London: McGraw-Hill Book Company, Inc., 1915, pp. XVIII+312, pls. 47, figs. 32*).—A text-book and manual of information dealing with the wood preserving industry, the subject matter being based largely on lecture notes prepared by the author for civil engineering students at the University of Wisconsin.

The introductory chapter deals with the importance and history of wood preservation. The succeeding chapters discuss the factors which cause the deterioration of structural timber, the effect of the structure of wood upon its injection with preservatives, the preparation of timber for its preservative treatment, processes and preservatives used in protecting wood from decay, the construction and operation of wood preserving plants, prolonging the life of cross-ties from decay and abrasion, prolonging the life of poles and cross-arms from decay and insects, prolonging the life of fence posts from decay, prolonging the life of piling and boats from decay and marine borers, prolonging the life of mine timbers, paving blocks, shingles, lumber, and logs, the protection of timber from fire and minor destructive agents, the strength and electrolysis of treated timber, and the use of substitutes for treated timber. Considerable information dealing with wood preservation, wood preserving processes, and data on the wood preserving industry of the United States, etc., is appended.

The deterioration of lumber.—A preliminary study, M. B. PRATT (*California Sta. Bul. 252 (1915), pp. 301-320, figs. 8*).—In the study here reported lumber from three important timber species, viz, sugar pine (*Pinus lambertiana*), western yellow pine (*P. ponderosa*), and Douglas fir (*Pseudotsuga taxifolia*), was under observation in the yards of a representative lumber company in the northern part of the Sierra Nevada Mountains of California from the time it left the sawmill until it was shipped. Data were secured relative to the loss in grade due to air seasoning, kiln drying, and finishing, and the causes leading to the loss.

The limited amount of data secured in this work show that the upper grades of sugar pine deteriorate much more in seasoning than either western yellow pine or Douglas fir. The average loss for all lumber tallied in unfinished upper grades of sugar pine through fall seasoning was approximately \$12 per thousand board feet as compared with an average loss of \$2.58 per thousand board feet through summer seasoning. One test in kiln drying sugar pine at the same temperature as western yellow pine and Douglas fir indicated that the deterioration in the upper grades of sugar pine lumber would be much less if kiln dried than when air dried in the spring or fall. Until the matter of kiln drying of sugar pine has been worked out more satisfactorily, however, it seems preferable to air dry the summer-cut stock.

Blue stain and brown stain, the greatest sources of depreciation in sugar pine lumber, are largely the result of poor drying conditions due to imperfect circulation of air, poorly drained soil, failure of a pile to shed rain water, or damp, rainy weather. The author concludes that since a large loss is liable to occur in air-seasoned sugar pine owing to the sensitiveness of the wood to blue stain and brown stain the value should be fixed in accordance with the ultimate grade and value of the species rather than its grade and value at the saw.

Since air-dried western yellow pine lumber checks so badly, it pays to kiln dry all of the upper grades. Approximately 80 per cent of western yellow pine tallied in this study retained the original grade as made at the mill after the lumber had been kiln dried and surfaced. The average loss through deterioration during kiln drying of the upper grades was approximately \$1.55 per thousand board feet. With lumber surfaced on two sides there was a further loss ranging from 51 cts. per thousand board feet in lumber taken directly from the kiln to \$2.27 per thousand board feet in that stored in the sheds.

Experience has shown that kiln drying is the only practical method of keeping up the grades of Douglas fir. Approximately 91 per cent of the upper grades of Douglas fir 1 in. in thickness retained the original grade when shipped after being kiln dried. The average loss through deterioration due to kiln drying was 53 cts. per thousand board feet for 1 in. lumber and \$2.90 per thousand board feet for 2 in. lumber, which checks very badly.

DISEASES OF PLANTS.

Physiological relations of powdery mildews to their hosts, G. M. REED (*Missouri Sta. Bul. 131 (1915), pp. 469, 470*).—It is stated that absence of light during the growth of barley and wheat results in a marked decrease of infection by powdery mildew; also a retardation in the development and a lengthening of the incubation period of the fungus. A marked correlation is noted between the violence of infection and the development of chlorophyll in etiolated plants.

A connection between mildew attack and photosynthesis is indicated by the fact that wheat and barley grown in the presence of light, but in the absence of carbon dioxide, remain free from mildew. Mineral starvation of the plant confers upon it partial immunity as regards the fungus, but it does so indirectly by lessening the vigor of the host and so depriving the parasite of its proper nutriment. Such substances as manganese sulphate, potassium sulphate, and lithium bromid added to the soil may slightly decrease susceptibility in the host. Dwarfing host plants by a high content of mineral in the soil water has no effect as regards susceptibility to mildew. There seems to be a positive correlation between normal development on the part of the host and successful attack on the part of the fungus.

Studies in the genus *Phytophthora*, J. ROSENBAUM (*Abs. in Phytopathology, 4 (1914), No. 6, pp. 394, 395*).—A study is reported of a number of species of *Phytophthora*, 10 of which have been collected and grown in cultures.

The results indicate that the kind of spores produced and the time of their appearance on a given medium is in some cases characteristic of the different species. Morphological studies also reveal characters of taxonomic importance. A great variation was found to exist in spore forms. From inoculation experiments the author concludes that the parasitism of species of *Phytophthora* is of a rather low order.

The *Verticillium* wilt problem, C. W. CARPENTER (*Abs. in Phytopathology, 4 (1914), No. 6, p. 393*).—*Verticillium* wilts are said to have been reported on potato, okra, eggplant, snapdragon, and dahlia.

Of the first three plants the parasite is said to be *V. albo-atrum*, while for dahlia wilt the cause is given as *V. dahliae*. In addition to attacking the hosts mentioned above, *V. albo-atrum* is believed to be the cause of a spontaneous wilting of two cotton plants at Arlington, Va. It likewise occurs in the vascular system of the weeds *Abutilon* and *Xanthium*, and is also the cause of the wilt of snapdragon. Attention is called to some views regarding the classification of the genus and its species, and the desirability of a monographic study is pointed out.

Classification of local rusts, J. P. BENNETT (*Missouri Sta. Bul. 131 (1915), p. 469*).—It is stated that there have now been collected and identified 67 species of rust occurring on 127 hosts obtained from 443 collections. It is thought probable that there are still at least as many more species occurring in Boone County that have not yet been collected.

The relation between *Puccinia graminis* and host plants immune to its attack, E. C. STAKMAN (*Abs. in Phytopathology, 4 (1914), No. 6, p. 400*).—In continuation of previous studies (E. S. R., 31, p. 146), the author states that in many cases, both with cereals resistant to a biologic form of *P. graminis* and wheats resistant in varying degrees to attacks of *P. graminis tritici*, varying degrees of infection occurred. In some cases fairly large areas of the host tissue were killed outright, in others the discolored portions indicating the death of the host tissue were extremely small. In extreme cases no spots whatever are visible to the naked eye. A histological study of the infection in such cases indicates that small areas of the leaf, comprising sometimes only four or five cells are killed and the fungus is then unable to develop further. In the case of normal infection the killing of the cells by the hyphæ does not seem to occur. Whether or not hypersensitiveness of the host plant toward *P. graminis*, which is unable to infect it, is a universal phenomenon is not yet determined.

Grain smut infections and control, G. M. REED (*Missouri Sta. Bul. 131 (1915), p. 469*).—In testing pure strains of wheat a wide range as regards susceptibility to bunt (*Tilletia fœtens*) was observed. A high degree of efficiency was indicated as regards the method of inoculation employed, which consisted simply in dusting the seed with the dry spores of the fungus. Treadwell proved to be less susceptible than Red Cross or Early Ripe. It has not yet been conclusively shown that late planting results in a high percentage of smut, but it has been proved that a high degree of soil contamination with smut spores causes smut in the subsequent crop.

The necessity for annual seed treatment of seed oats for loose smut (*Ustilago lœvis*) is indicated. A wide variation in susceptibility was noted, some supposedly resistant varieties proving to be otherwise. The common method of treating seed oats with formalin (1 lb. to 40 gal. water) is said to be absolutely effective in preventing the smut.

A bacterial leaf-spot disease of celery, I. C. JAGGER (*Abs. in Phytopathology, 4 (1914), No. 6, p. 395*).—The author reports having had under observation in central and western New York for the past five years an apparently undescribed leaf spot of celery. It is said to occur very commonly in that region, but so far only a few cases of noticeable injury to the crop have been observed. Spots of a rusty brown color, irregular in outline, are formed on the leaves, from which bacteria have been repeatedly isolated and characteristic spots reproduced by inoculation. The bacterial spots closely resemble those due to Septoria, being distinguished by means of the pycnidia in the spots formed by the fungus.

Downy mildew of cucumbers, G. E. STONE (*Massachusetts Sta. Circ. 51 (1915), pp. 2, fig. 1*).—This is a revision of Circular 40 (E. S. R., 32, p. 342).

The control of onion smut, G. E. STONE (*Massachusetts Sta. Circ. 52 (1915), pp. 4, figs. 4*).—This is a revision of Circular 41 (E. S. R., 32, p. 342).

Leaf spot and some fruit rots of peanut, F. A. WOLF (*Abs. in Phytopathology, 4 (1914), No. 6, p. 397*).—The substance of this note has been previously given (E. S. R., 32, p. 546).

Effect of temperature on germination and growth of the common potato scab organism, M. SHAPOVALOV (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 2, pp. 129-134, pl. 1, fig. 1*).—This is a brief account of studies on the potato scab organism formerly known as *Oospora scabies*, but recently claimed by Lutman and Cunningham (E. S. R., 32, p. 546) to be identical with *Actino-*

myces chromogenus. Several strongly pathogenic strains were studied at the Maine Experiment Station after being isolated from diseased specimens from Maine, Vermont, and Wisconsin.

It is stated that while temperatures of 35 to 40° C. are most favorable for germination of the gonidia, they are unfavorable for long continued growth, although at 35° a stimulating effect was produced at first. The maximum temperature for growth is about 40.5°, the optimum 25 to 30°, and the minimum about 5°.

Involution forms appeared abundantly when 0.25 per cent of potassium monophosphate was included in a synthetic culture medium, but none resulted from temperature conditions.

The use of sulphur for the control of potato scab, H. C. LINT (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 396, 397).—Investigations have been carried on to obtain data regarding the effectiveness of sulphur for the control of potato scab, and also to determine the influence of the various factors involved.

The results thus far obtained indicate that spring applications are more satisfactory than fall applications. The benefits derived from the use of sulphur were greater when applied to land on which no cover crop had been grown the preceding season than on land where such a crop had been used. Seed treatment with formaldehyde and the application of sulphur to the soil gave better results than the sum of these two treatments used separately. Broadcasting of the sulphur on the soil after planting is considered the best method of application. When used in connection with fertilizers, sulphur was found more effective with ammonium sulphate than with sodium nitrate, with acid phosphate than with steamed bone, and with muriate than with sulphate of potash.

Seedling diseases of sugar beets and their relation to root rot and crown rot, H. A. EDSON (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 2, pp. 135-168, pls. 11).—A study is reported of damping off in beets, also of another seedling trouble designated as root sickness, together with associated rots of the growing or of the mature root. Some factors influencing the health of the plants, as alkali injury, are also discussed.

Four fungi casually related to damping off are *Phoma beta*, *Rhizoctonia* sp., thought to be identical with *Corticium vagum solani*, *Pythium debaryanum*, and an undescribed member of the Saprolegneaceæ. While plants attacked by the first two may recover temporarily or permanently, those suffering from the other two usually succumb. *Phoma* and *Rhizoctonia* produce a characteristic decay in mature beets, the former infecting primarily the seedling and remaining after recovery in a dormant condition on the host, developing occasionally a characteristic black rot on growing beets in the field, and being noted frequently on beets in storage. It may destroy the root or appear on the seed stalk and the mature seed.

Control measures are to be sought in proper cultural methods and seed treatment looking to the production of uninfected seed.

P. debaryanum is capable of attacking the feeding roots of the beet throughout its vegetative period, and may attack the mature beets.

Rhizopus-nigricans is found to attack the tissue of dead or dormant sugar beets, producing a characteristic decay.

A bibliography of cited literature is appended.

Phoma beta on the leaves of the sugar beet, VENUS W. POOL and M. B. MCKAY (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 2, pp. 169-178, pl. 1).—The authors found that *P. beta* produces a characteristic infection on leaves that have a stomatal count of 60 to 100 per square millimeter on the upper leaf surface, a low physiological condition permitting infection of all except the

heart leaves. The spots bearing pycnidia usually appear during July and August on old or yellowing leaves near the ground, the pycnosporos being disseminated by such agencies as beet balls, wind, irrigation water, insects, and manure.

P. betæ in leaf tissue is killed in $\frac{1}{2}$ hour by dry heat of 80 to 90° C., in 3 months by storage in boxes of soil exposed to outdoor conditions, in 5 to 8 months by burial in the ground, but apparently in 2 months by ensiling. A period of one year seems sufficient to eliminate *P. betæ* from an infected field, with the possible exception of the mycelium in a sugar beet root or mother beet stalk. No evidence of a perfect stage of the organism was found.

Blossom-end rot of tomatoes, C. BROOKS (*New Hampshire Sta. Sci. Contrib.* 8 (1914), pp. 345-374, pls. 3, figs. 5).—A reprint of an article previously noted (E. S. R., 32, p. 343).

Resistance to *Cladosporium fulvum* in tomato varieties, J. B. S. NORTON (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 398).—The author reports a study of 256 plants of 14 varieties of tomato grown in the greenhouse in the early spring of 1914, nearly all of which were badly affected with *Cladosporium*, except Stone and Sterling Castle, which were practically immune.

Loss from mosaic disease of tomato, J. B. S. NORTON (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 398).—The author reports the extensive occurrence of a mosaic disease of tomato in Maryland. Greenhouse experiments showed that the plants first attacked by the disease bore scarcely less weight of fruit than those which remained healthy longest, but healthy plants set 33 per cent more fruit than infected ones.

Orchard experiments in 1914, M. T. COOK and G. W. MARTIN (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 394).—A brief account is given of experiments carried on by the New Jersey Experiment Stations, in which finely divided sulphur was applied to peach orchards.

The results indicate that scab was successfully controlled, although some of the trees were partly defoliated. On apple trees finely divided sulphur did not give as good results as lime sulphur.

Hosts of brown rot *Sclerotinia*, J. S. NORTON (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 398).—Inoculation experiments with conidia of the common brown rot fungus of orchard fruits have shown that conidia developed on the cherry, wild-goose plum, blackberry, Japanese plum, Damson plum, green corn, pear, peach, apple, wild black cherry, strawberry, crab apple, *Crataegus*, *Pyrus betulifolia*, dried prune, peach, apricot, and raisin. About 50 species of plants, including *Rosa*, *Amelanchier*, *Rubus occidentalis*, *P. arbutifolia*, and *Cydonia japonica*, showed no outward sign of infection.

Apple fruit spot and quince blotch, C. BROOKS and CAROLINE A. BLACK (*New Hampshire Sta. Sci. Contrib.* 5 (1912), pp. 63-72, pls. 2).—A reprint of an article previously noted (E. S. R., 27, p. 652).

Apple leaf spot, C. BROOKS and MARGARET DEMERITT (*New Hampshire Sta. Sci. Contrib.* 6 (1912), pp. 181-190, pl. 1).—A reprint of an article previously noted (E. S. R., 28, p. 548).

Apple rust or cedar rust in West Virginia, N. J. GIDDINGS and A. BERG (*West Virginia Sta. Circ.* 15 (1915), pp. 16, figs. 7).—Discussing briefly the life history of the apple and cedar rust fungus, the author describes attempts at control by preventive treatment.

Control by use of sprays, while possible, seems impracticable for the commercial orchardist. Destruction of cedar trees seems effective if complete, and practicable, costing less than 48 cts. per acre over 1.113 acres experimented upon. It is believed that the cedar-free area should cover a radius of at least a mile around an orchard.

Apple varieties show a very wide range of susceptibility, and even different trees of the same kind show variation. Lists are given of varieties found to be immune, resistant, or more or less susceptible.

Treatment of apple canker diseases, J. C. WHITTEN (*Missouri Sta. Bul.* 131 (1915), p. 483).—The indications are that whitewashing the trunk of apple trees protects them from the entrance of canker by preventing the undue rise of temperature and resulting scald on the sunny side of the tree.

Canker can be eradicated if treatment is commenced before it has gone so deep as to weaken the wood of the tree.

A nursery disease of the peach, M. T. COOK and C. A. SCHWARZE (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 394).—The authors' attention was called to a peculiar disease of Elberta peaches in the nursery in 1914.

The disease is said to attack the young shoots a few inches back of the tips, producing cankers on one side and causing a characteristic curving as a result of the growth on the uninjured side. The cankers originate as small brown spots and gradually enlarge until they are 2 or 3 cm. in length. The diseased area becomes brown and depressed, and finally splits down the center. Gum exudes from the split. The causal organism is considered a species of *Sphaeropsis* and successful inoculation experiments have been carried on with it. So far as the authors' observations go, the trouble is of rather limited distribution.

A wilt disease of Japanese and hybrid plums, B. B. HIGGINS (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 398, 399).—For a number of years a destructive disease, locally known as plum wilt, has been reported to the Georgia Experiment Station, and investigations have been conducted regarding its cause.

According to the author the disease is caused by a fungus which enters through wounds, the hyphæ passing rather slowly toward the center of the tree, as well as up and down through the water ducts, causing the formation of gum which plugs the water ducts and cuts off the water supply. The leaves wilt suddenly and then dry up. Apparently about a year is consumed from the infection to the death of the tree. The fungus has been isolated, grown in cultures, and its parasitism demonstrated by means of inoculation, but the identity of the organism has not been determined.

Studies on *Plasmopara viticola*, C. T. GREGORY (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 399).—In a study of the downy mildew of the grape the author found that infection could take place only through stomata, never through injuries. Experiments have demonstrated that conidia sown on the upper surface of the leaf could cause infection provided a continuous film of water extends over the margin to the lower surface. The discoloration of the lesions is considered due to decomposition of the chlorophyll and chloroplastids. The swelling of the stem of the host is said to result from the hypertrophy of the cells and the intussusception of mycelium between the cells.

The conidiophores are usually said to be produced through stomata, though they may burst through the loose tissue above the veins or directly through the epidermis of the flower pedicel. The inability of the fungus to fruit on older berries is considered due to the absence of stomata.

Citrus canker, A. B. MASSEY (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 397).—This is a brief note on the occurrence of citrus canker in south Alabama and elsewhere, a previous account of which has been given (*E. S. R.*, 32, p. 53).

A new rust of economic importance on the cultivated snapdragon, G. L. PELTIER and C. C. REES (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 400).—According to the authors the snapdragon is becoming of some importance as a greenhouse crop. Recently the culture has been interfered with by a new rust.

This was first observed in the vicinity of Chicago in 1913, and in 1914 was reported in a number of localities in Ohio and Indiana.

The rust appears on the plants in the field about the last of July, the uredo stage persisting until fall, when the teleuto pustules may be found on the stems and branches. The uredo stage may be also found in the greenhouse throughout the winter on cuttings and seedlings, and later on mature plants. Toward spring the rust seems to die out in the house, reappearing in the summer. The fungus was first described as *Puccinia antirrhini* in 1895, but there seems to be no reference to the rust since that time.

A Nectria parasitic on Norway maple, M. T. COOK (*Abs. in Phytopathology, 4 (1914), No. 6, p. 396*).—The author reports having observed for the past two years a disease of Norway maple, symptoms of which bear striking resemblance to those of the chestnut bark disease due to *Endothia parasitica*.

The leaves of the infected maple trees wilt and the branches die. Observations showed that the trouble was due to a canker which girdled the branches. The infection usually occurs through a wound. The causal organism is considered probably *N. cinnabarina* or *N. coccinea*. On an isolated group of Norway maples the disease has proved very destructive. It was also found in a nursery, but here the fungus was apparently saprophytic.

Thrombotic disease of maple, W. H. RANKIN (*Abs. in Phytopathology, 4 (1914), No. 6, pp. 395, 396*).—The first indication of this disease, found near Claverack, N. Y., is a withering and drying of the leaves without change of color except a slight blanching. After one limb of a tree becomes affected, other limbs either directly above or below are killed, the disease progressing until within a month or two the tree is dead.

An examination of a diseased limb showed no fruiting bodies of a fungus, and the bark on recently killed limbs was found apparently healthy. Upon cutting into the sapwood of the current season's growth, it was found to be streaked with dark-green lines. The mycelium of a fungus was abundant, and the dark-green streaking is said to be due to the abundant production of sclerotia, which were packed in the vessels. The causal fungus was found to be a species of *Acrostalagmus*.

Inoculation experiments and other investigations are said to be in progress.

A mutation in Phyllosticta, C. H. CRABILL (*Abs. in Phytopathology, 4 (1914), No. 6, p. 396*).—The author reports observing in studies of several species of fungi isolated from frog eye leaf spot of apple one which answers closely to the descriptions of *Phyllosticta*, except that it produces chlamydospores. This is believed to be a mutant from the usual form of the fungus.

The perfect stage of Phyllosticta paviæ, V. B. STEWART (*Abs. in Phytopathology, 4 (1914), No. 6, p. 399*).—The author reports observing the mature perithecia in May, 1914, on the underside of diseased horse chestnut leaves that had been exposed to the winter. Cultures made from the perithecia and transferred to horse chestnut seedlings produced the characteristic lesions of the leaf blotch within 10 days, indicating that the perithecia are the perfect stage of the fungus *P. paviæ*.

Comparing this stage of the fungus with one previously described by Peck, the author finds that they are identical, so that the name for the sexual stage of the fungus should be *Lastadia asculi*.

The longevity of pycnospores and ascospores of Endothia parasitica under artificial conditions, F. D. HEALD and R. A. STUDHALTER (*Phytopathology, 5 (1915), No. 1, pp. 35-44, pl. 1; abs. in Phytopathology, 4 (1914), No. 6, p. 401*).—The author states that pycnospores in suspension in water show a slow but gradual reduction in the number remaining viable. At temperatures from

42 to 75° F., one-third were viable at the end of 49 days. At freezing temperature or below the loss of vitality was less pronounced. When separated and allowed to dry, pycnospores were found less resistant than if dried in the form of sporehorns. When dried on glass, from 66 to 78 per cent were killed by the process, and none remained viable for more than 2 weeks.

When separated and allowed to dry from suspension in water, ascospores were found much less resistant to desiccation than when dried in perithecia or as spore-prints on object slides. When so separated, from 86 to 94 per cent of the ascospores were killed in the process of drying, and none remained viable more than 35 days.

The vitality of separated spores when dried on living leaves or bark was found to be much greater than when dried on a glass surface.

An unreported fungus on the oak. C. A. SCHWARZE (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 396).—The author reports a leaf spot on the black oak, chestnut oak, and red oak in different parts of New Jersey, in which the spots are from 3 to 8 mm. in diameter and light reddish-brown in color with a narrow dark brown border. Examination showed the presence of a fungus which is very similar to, if not identical with, *Actinopelte japonica*.

Notes on soil disinfection. C. HARTLEY (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 398).—Information additional to that previously noted (*E. S. R.*, 31, p. 647) is given regarding experiments conducted with soil disinfection for pine seed beds.

Heating has proved a failure on account of the fact that the soil is left in a condition suitable for the reestablishment of parasites. Sulphuric acid, copper sulphate, and zinc chlorid were more effective than formaldehyde, and were fairly satisfactory even when applied the preceding autumn. The use of acids was found cheaper than formaldehyde, and has given rather satisfactory results except on soils containing carbonates, where acids have failed and toxic salts have proved the best. The precipitation of copper salts was found to be delayed by adding ammonia. A large number of other substances have been tested, but only sugar, acetylene, and arsenicals seem to be worthy of further consideration.

The acid treatment, followed two days later by an application of lime, is recommended as a possible substitute for heating for crops that do not tolerate acid alone.

Nematodes and their relationships. N. A. COBB (*U. S. Dept. Agr. Yearbook 1914*, pp. 457-490, figs. 20).—This is a somewhat popularized discussion of nematodes in general and also as curious, harmful, or helpful organisms. It is intended to indicate to the general reader the vast number of nematodes that exist, the enormous variety of their forms, and the intricate and important relationships they sustain directly or indirectly to mankind.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Field mice as farm and orchard pests. D. E. LANTZ (*U. S. Dept. Agr., Farmers' Bul. 670 (1915)*, pp. 10, figs. 7).—This deals with the habits, distribution, and methods of combating meadow and pine mice. The protection of the natural enemies of mice is also touched upon.

Our shore birds and their future. W. W. COOKE (*U. S. Dept. Agr. Yearbook 1914*, pp. 275-294, pls. 3, figs. 3).—This is a discussion of the habits of shore birds, particularly as their migration habits relate to the problem of protection. It is pointed out that few shore birds put less than a thousand miles between their nest and winter home, and most of them make a trip of several thousand miles each way. Among the species considered are Wilson snipe, woodcock, up-

land plover, Eskimo curlew, etc. While excessive shooting, due to inadequate state laws, has resulted in their recent decrease in numbers, it is thought that with the wise administration of a federal law they will again become common enough to afford the hunter a fair amount of legitimate sport.

Eleven important wild duck foods, W. L. MCATEE (*U. S. Dept. Agr. Bul. 205 (1915)*, pp. 25, figs. 23).—In this bulletin, the third of a series on the subject (*E. S. R.*, 30, p. 545), the author shows how eleven groups of plants may be successfully used as food for wild ducks in localities where now unknown.

Those here described are musk grasses, duckweeds, frogbit (*Limnobium spongia*), thalia (*Thalia divaricata*), water elm (*Planera aquatica*), swamp privet (*Forestiera acuminata*), eel grass (*Zostera marina*), wigeon-grass (*Ruppia maritima*), water cress (*Sisymbrium nasturtium-aquaticum*), water weed, and coontail (*Ceratophyllum demersum*).

Mortality among waterfowl around Great Salt Lake, Utah, A. WETMORE (*U. S. Dept. Agr. Bul. 217 (1915)*, pp. 10, pls. 3).—This is a report of progress in investigations carried on by the Biological Survey in Utah and California with a view to determining the cause and means for preventing the extremely high mortality among ducks and other waterfowl. It is shown that untold thousands of wild ducks, snipe, sandpipers, and other birds of less economic value which frequent the marshes along the eastern shore of Great Salt Lake and other localities, as Tulare and Owens lakes, California, perish annually. During the work in Utah in 1914, 27 species of birds of 11 families were found to be affected. "Among these were 9 species of ducks, 10 of shore birds, and 8 miscellaneous forms ranging from grebes and snowy herons to the pipit. Among ducks the pin-tail and green-winged teal seemed to be most susceptible, while the mallard, spoonbill, and cinnamon teal followed them closely. Avocets and stilts suffered more heavily than any other shore birds.

"The birds affected first lose the power of flight and are unable to rise in the air, though in some cases they can flutter across the water and in others can fly for a few rods before dropping back. The legs next become affected and the power of diving is lost. As the birds grow weaker they crawl out on the mud bars, if able to do so, or hide in growths of grass or rushes. In a later stage of the affection they are unable to rise. Finally the neck relaxes and the head lies prostrate. If in the water death comes by drowning, but on land birds may live for two days or more in this condition.

"A large series of post-mortem examinations revealed no pathological lesions other than that the intestine was reddened and firm and hard to the touch. When the gut was slit, washed, and examined under a low magnification, the capillaries in the intestinal villi were found to be distended, showing intense irritation. . . . A severe dysentery occasioned by the irritation of the intestine was the obvious external symptom."

Reference is made to the numerous theories that have been advanced to account for the mortality, including bacterial infection, parasitic nematodes, smelter and factory waste, etc., all of which appear to have been eliminated as the probable cause. Pathological investigations of affected birds, a brief report of which by J. R. Mohler, of the Bureau of Animal Industry of this Department, is presented, have led to the conclusion that the affection is probably an acute poisoning and not of bacterial origin. The author states that the work of the past summer has led him to conclude that the mortality results from an alkaline poison the nature of which is still to be determined. The absence of lesions in any of the organs, other than a severe irritation in the lumen of the intestine, the fact that practically all the affected birds are fat, that a large percentage of the birds recover when given fresh water, etc., all point to this conclusion. It is

pointed out that as soon as irrigation ceases and there is a great increase in the amount of river water entering the constant flow steadily drains the flats and removes the stagnant water. As a result the mortality ceases almost at once. Fresh water is the only remedial measure yet discovered.

Some data on the effect of temperature and moisture on the rate of insect metabolism, T. J. HEADLEE (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 413-417).—The author finds that the rate of metabolism in certain actively feeding insects with an abundant supply of succulent food is not affected by large differences in atmospheric moisture.

On the valuation of lime-sulphur as an insecticide, H. V. TARTAR (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 463-467).—It is stated that the work done by the department of entomology of the Oregon Experiment Station indicates clearly that the calcium polysulphids are the principal insecticidal constituents of lime-sulphur. Experimental work carried on at the laboratory indicates that if hydrogen sulphid is liberated under normal conditions it is in very small quantity and evidently is not an important factor to consider.

Insecticide formulas, C. W. WOODWORTH (*California Sta. Circ.* 128 (1915), pp. 7).—Formulas for the preparation of various insecticides are given in the order of their importance in California.

Twenty-ninth report of the state entomologist, 1913, E. P. FELT (*Univ. State N. Y. Bul.* 589 (1915), pp. 257, pls. 16, figs. 36).—Under the heading of Injurious Insects (pp. 13-44) the author briefly reports upon control work with the codling moth during the year in continuation of that of the preceding four years (E. S. R., 30, p. 656), and gives brief accounts of the lined corn borer (*Hadena fractilinea*), which was the source of injury to corn through boring into the heart and killing the stalks in Ulster County; the European grain moth or wolf moth (*Tinea granella*), an important cereal pest discovered in a seed warehouse at Albany, where it had nearly destroyed hundreds of bushels of sweet corn; *Sesia rhododendri*, said to be generally distributed in New York Zoological Park and common in and about Prospect Park, Brooklyn, and also recorded from Cheltenham, Pa.; the azalea leaf skeletonizer (*Gracilaria azaleæ*) which injured azaleas in greenhouses at Yonkers and Rochester; the arbor vitæ leaf miner (*Argyresthia thuiella*) which was abundant at Westbury; white grubs and June beetles; the spotted hemlock borer (*Melanophila fulvoguttata*) which caused the death of hemlock in the New York Botanical Garden; the white pine weevil (*Pissodes strobi*), which is widely distributed; the hickory bark borer (*Eccoptogaster quadrispinosa*); the pitted ambrosia beetle (*Corthylyus punctatissimus*), which injured rhododendrons at Irvington and Tarrytown; the cactus midge (*Itonida opuntiae*); and the banded grape bug (*Paracalocoris scurpeus*), a pest of grapes which is increasing in numbers in western New York and damages grapes in the Niagara district.

In a brief discussion of the use of miscible oils on trees (pp. 45-47), the author states that the data at hand abundantly justify a refusal to recommend these materials as applications to dormant sugar maples and warrant the employment of caution in their use in a similar way for other trees.

Under the heading of Notes for the Year (pp. 48-67), accounts are given of the occurrence of a number of important insects, including *Aspidiotus osborni*, not previously recorded from the State, and *Pulvinaria acericola*, two rare scales, which were found during the past season, the former at Scarborough and the latter at Tarrytown. Fruit-tree pests noted are the apple tent caterpillar, plum curculio, pear thrips, false red bug (*Lygidca mendax*), pear psylla, plant lice, San José scale, and the variegated cutworm (*Agrotis saucia*).

Among those mentioned as attacking shade trees are the elm leaf beetle (*Galerucella luteola*), the English elm pouch gall (*Tetrancura ulmisaccuti*), the false maple scale (*Phenacoccus acericola*), spruce bud scale (*Physokermes picea*), and tulip tree scale (*Toumeyella liriodendri*). Forest tree pests noted include the forest tent caterpillar, locust borer (*Cyrtene robiniae*), and spruce aphid (*Mindarus abietinus*). Among the miscellaneous insects noted are the drug-store beetle (*Sitodrepa panicea*), mason bees (*Osmia felti*), white winged Bibio (*Bibio albipennis*), and *Bolitophila cinerea*.

Lists are given of publications of the entomologist and additions to collections. In an appendix, which is part 2 of A Study on Gall Midges (E. S. R., 30, p. 656), the author deals with the subfamily Itonididinae, which comprises by far the larger number of the family and includes practically all the gall making forms. Keys to the tribes, genera, and species and colored plates of the galls formed are included.

Additional notes on Porto Rican sugar cane insects, T. H. JONES (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 461-463).—The data here presented are supplementary to those given in the accounts by Van Dine, previously noted (E. S. R., 29, p. 353; 30, pp. 355, 356).

The California pear thrips in Maryland, W. M. SCOTT (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 478, 479).—The author reports the discovery of this pest in a small Kieffer pear orchard near Baltimore, where the leaves were curled and blackened at the tips and around the margins, and most of the blossom clusters destroyed.

The status of spraying practices for the control of plant lice in apple orchards, P. J. PARROTT and H. E. HODGKISS (*New York State Sta. Bul.* 402 (1915), pp. 193-210, pls. 2, figs. 2).—Three species of plant lice, the rosy apple aphid (*Aphis sorbi*), apple aphid, and oat aphid (*A. arceae*), are injurious to apples in New York, the two former normally causing the greatest losses in crop production. It is pointed out that experiments by the station indicate that the most effective and satisfactory means of protecting young fruit during its formative stage is through the destruction of plant lice on the expanding buds.

"The most efficient spraying mixtures are nicotin solution, oil emulsions, or soap preparations. The physical features of the location of the orchard, such as the direction and elevation of the slopes of the land, proximity of water and character of soil, have a marked influence on the development of the buds. The time for effective spraying will therefore vary with individual orchards as well as with different varieties of apples."

Controlling plant lice in apple orchards, F. H. HALL (*New York State Sta. Bul.* 402, popular ed. (1915), pp. 3-7, figs. 2).—A popular edition of the above.

Four aphids injurious to the apple, B. S. PICKETT (*Illinois Sta. Circ.* 179 (1915), pp. 4).—The species noted are the apple aphid, the rosy apple aphid (*Aphis sorbi*), the European grain aphid, and the clover aphid (*A. bakeri*).

Control of the San José scale in Missouri, L. HASEMAN (*Missouri Sta. Bul.* 132 (1915), pp. 9, figs. 4).—With the passage of the Nursery and Orchard Inspection Act in 1913, the station was authorized not only to inspect for insect pests and diseases but also to assist with the cleaning up where these were found. Since the San José scale was the one pest of most vital importance to horticulture in the State steps were at once taken to assist in its eradication.

Spray experiments are said to show that two applications, one in late fall and one in the spring before the buds open, are required in the case of badly infested orchards. Where but one application is made equal results are obtained from a late fall or early spring application. It is stated that so far as the control of the San José scale alone is concerned, lime-sulphur and commercial miscible oils gave practically the same results.

Notes on Coccidæ found in Peru, E. W. RUST (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 467-473).—A discussion of the occurrence of some twenty species of Coccidæ in Peru.

Report on the gipsy moth work in New England, A. F. BURGESS (*U. S. Dept. Agr. Bul.* 204 (1915), pp. 32, pls. 11, figs. 3).—This is a report of progress in the work against the gipsy moth now under way by the Bureau of Entomology of this Department, especially that with parasites. The importance of bringing forest lands into a growth which is unfavorable to the development of the gipsy moth is emphasized.

Maps which show the dispersion of natural enemies in New England, including *Apanteles lacticolor*, *Compsilura concinnata*, and *Calosoma sycophanta*; the towns in New England in which silvicultural experiments are being conducted; the areas in New England infested with the gipsy and brown-tail moths in 1914; and the gipsy moth quarantine districts are attached.

Wilt of gipsy moth caterpillars, R. W. GLASER (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 2, pp. 101-128, pls. 4, figs. 17).—This is a summarized account of the present status of our knowledge of the wilt disease of gipsy moth caterpillars, based upon a review of the literature and investigations carried out by the author, an employee of the Bureau of Entomology of this Department. The data presented have been summarized as follows:

“The wilt of gipsy moth caterpillars is a true infectious disease that is distributed over the entire territory infested by the gipsy moth. Epidemics of the disease occur only in localities heavily infested by the gipsy moth. Climatic conditions appear to bear an important relation to wilt in the field. The disease is more prevalent among older than among younger caterpillars, but small caterpillars also die of it in the field. No diagnosis of wilt is valid unless polyhedra are demonstrated microscopically. There is no account of the occurrence of wilt in America prior to 1900. Minute dancing granules may be observed in wet smears. Polyhedra are probably reaction bodies belonging to the highly differentiated albumins, the nucleoproteids. The pathology of wilt does not vary with the age of the caterpillars. The polyhedra originate in the nuclei of the tracheal matrix, hypodermal, fat, and blood cells. The nuclei of the tracheal matrix and blood cells seem to be the first tissue nuclei affected. Many minute violently dancing granules are found in the pathological nuclei of fresh tissue. Giemsa's stain demonstrates many little granules in the nuclei of diseased tissue sections. The alimentary canal seems to be the last organ in the body to disintegrate.

“Two types of blood corpuscles exist in normal hemolymph. Two types of pathological blood corpuscles exist in diseased caterpillars. The blood is a fairly reliable index of a caterpillar's condition. The blood test is impracticable for large experimental series. Bacteria are not etiologically related to wilt. The virus of wilt is filterable with difficulty. Such a filtrate is free from bacteria and polyhedral bodies. Caterpillars that have died from infection with filtered virus are flaccid, completely disintegrated, and full of polyhedra. Minute dancing granules were observed in the Berkefeld filtrate. These may be identical with certain granules observed in smears and tissue nuclei and may be etiologically significant. The incubation period of wilt varies, and temperature at times seems to bear an important relation to this variation. A large number of caterpillars used in the experiments died of disturbances in their normal physiological activities. The success of wilt infection experiments is absolutely dependent upon attention to seemingly insignificant details. Genetic immunity of certain individuals is probable. Active immunization with sublethal doses is possible. The polyhedral bodies may be stages of the fil-

terable virus, but as yet no evidence to substantiate this view has been produced. Infection naturally takes place through the mouth by means of the food. Some of the imported parasites may be important factors in aiding the dispersion of the wilt disease. Although probable, there is no definite evidence as yet that wilt is transmitted from one generation to another."

A list of 18 titles relating to the subject is included.

The squash-vine borer, F. H. CHITTENDEN (*U. S. Dept. Agr., Farmers' Bul. 668 (1915), pp. 6, figs. 2*).—A revision of Circular 38 of the Division of Entomology, in which a popular account is given of the distribution, food habits, natural history, and preventive and remedial measures for this pest.

The verbena bud moth, D. E. FINK (*U. S. Dept. Agr. Bul. 226 (1915), pp. 7, pls. 3, fig. 1*).—A summarized account of the life history and habits of, and of control measures for, the verbena bud moth (*Olethreutes hebesana*). This moth appears to confine its injury solely to flowering plants, having been reared from tiger flower (*Tigridia pavonia*), snapdragon (*Antirrhinum* spp.), flag (*Iris* spp.), hedge nettle (*Stachys palustris*), mullein (*Verbascum thapsus*), verbena (*Verbena* spp.), closed gentian (*Gentiana andrewsii*), and false foxglove (*Dasystema flava*). Injury is caused through its attacking the stems, feeding upon flower heads, webbing seed capsules together to feed upon the young and undeveloped seeds, and feeding upon dry pods.

The eggs are deposited singly or in groups of from three to five on sepals of flower buds or along the upper part of the flower stalk and hatch in from seven to ten days. Under laboratory conditions the life cycle occupied 43 days as follows: Eggs deposited March 2 hatched March 10, the larvæ pupated March 31, and the adults appeared April 14. During July and August in 1913 the life cycle was passed in 34 days. In the vicinity of Norfolk, Va., where the observations were made in cooperation with the Virginia Truck Station, at least five or six generations are produced each year.

The methods of control found effective against the larvæ include the application of arsenicals and the cutting back and destroying of infested flower stalks.

A bibliography of ten titles relating to the subject is included.

The serpentine leaf-miner on cotton, E. A. MCGREGOR (*Jour. Econ. Ent., 7 (1914), No. 6, pp. 447-454, figs. 8*).—A report of studies at Batesburg, S. C., of the dipterous leaf miner *Agromyza scutellata* on cotton. The paper supplements a general account of the pest by Webster and Parks, previously noted (*E. S. R., 29, p. 857*) in which they refer to it as *A. pusilla*.

List of zoophagous Itonididæ, E. P. FELT (*Jour. Econ. Ent., 7 (1914), No. 6, pp. 458, 459*).—A list is given of 29 reared species.

Arthrocnodax constricta n. sp., E. P. FELT (*Jour. Econ. Ent., 7 (1914), No. 6, p. 481*).—The itonidid here described was reared at Rio Piedras, P. R., from garden beans infested with the common red spider, upon which it is thought to be predaceous.

The losses to rural industries through mosquitoes that convey malaria, D. L. VAN DINE (*Reprint from South. Med. Jour., 8 (1915), No. 3, pp. 184-194, figs. 2*).—A discussion of the mosquito-malaria problem in the South and of investigations being carried on by the Bureau of Entomology of this Department. The investigations under way consist of survey work, climatological observations, biological and pathological work, and experimental control work.

The details of an intensive study which is being made of malarial conditions on a plantation of 3,500 acres located at Mound, La., in a region on the Mississippi where malaria is prevalent, are presented. It is shown that 48 out of 74 tenant families on the plantation were treated by the physician for malaria during the crop season of 1914, and that a total loss of 1,842 days, representing

1,066 days of adult time, resulted. Details relating to the occurrence of and loss of time from malaria are presented in tabular form.

While three species of Anopheles, namely, *Anopheles quadrimaculatus*, *A. punctipennis*, and *A. crucians*, occur in the vicinity of Mound, La., the first mentioned is by far the most abundant and is apparently the species concerned as the conveyor of malaria in that region. Observations on breeding places show that *A. quadrimaculatus* is partially domestic in its breeding habits.

The introduction of a tachinid parasite of the sugar cane weevil borer in Hawaii, O. H. SWEZEY (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 455-457).—A description of the manner in which *Ceromasia sphenophori* was introduced into Hawaii from British New Guinea. A reference to its introduction into Fiji by Illingworth has previously been noted (E. S. R., 32, p. 350).

This tachinid was first discovered at Amboina, in the East Indies in 1908, by Muir, where it parasitizes a weevil infesting sago palm. An attempt to introduce it into Hawaii from that locality failed on account of the relay stages of the journey having been too long. It was later discovered in British New Guinea destroying a high percentage of the borers in sugar cane. The first attempt to introduce the pest from New Guinea into Hawaii failed on account of the illness of Mr. Muir but a second attempt later was successful, living parasites having reached Honolulu in August, 1910. The author states that at the time of writing after a period of three years the parasites are established almost entirely throughout the sugar cane districts of the Hawaiian Islands. In plantations where the borers previously caused the greatest damage to cane, little damage is now occasioned.

On the original habitat of *Stomoxys calcitrans*, F. MUIR (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 459, 460).—The author believes that the stable fly originated in Africa.

Susceptibility of *Pollenia rudis* to nicotin, P. J. PARROTT (*Jour. Econ. Ent.*, 7 (1914), No. 6, p. 487).—A nicotin preparation consisting of 90 per cent nicotin and 10 per cent water applied by means of a small wad of cotton to the sills at the base of window panes in laboratories at the New York State Station, where the "cluster fly" had been numerous and annoying, caused the death of a large percentage of the insects within a short period of time.

The probable best method of rearing certain scarabæid larvæ, A. A. GIBAULT (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 445-447).—A description of the author's method, developed at the Bureau of Sugar Experiment Stations in Queensland.

Agrilus politus infesting roses, H. E. WEISS (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 438-440).—During the course of nursery-inspection work in northern New Jersey attention was called to the death of standard roses, the stems of which were swollen somewhat at different points. The buprestid beetles which emerged apparently represent the species *A. politus*, previously recorded as reared only from willow.

A new pest of cane in Fiji (*Sphenophorus nebulosus*), J. F. ILLINGWORTH (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 444, 445).—This article deals with a small beetle borer resembling the ordinary cane borer (*Rhabdocnemis obscurus*). It is apparently *S. nebulosus*, which, though exceedingly prolific, has as yet done little damage to sound cane in Fiji.

Some coccinellid statistics, H. E. EWING (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 440-443, fig. 1).—This article includes a table which shows the relative abundance of different species of coccinellids in five different situations, namely, on hops, thistles, lamb's quarters, kale, and vetch, and a diagram showing the relative numbers, expressed in percentage terms, of the total population of different species found in each patch.

Notes on the rice water weevil (*Lissorhoptrus simplex*), J. L. WEBB (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 432-438, pl. 1, figs. 2).—These notes are supplementary to the accounts by Tucker (E. S. R., 27, p. 562) and Newell (E. S. R., 29, p. 259). Careful experiments are said to have determined that drainage is still the safest remedy for the rice water weevil.

Effect of temperature upon the oviposition of the alfalfa weevil (*Phytonomus posticus*), T. H. PARKS (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 417-421, pl. 1, fig. 1).—The author reports upon a series of oviposition experiments with *P. posticus* conducted at Salt Lake City in 1911 and 1912 in which the variation in mean daily temperature throughout the oviposition period of the weevils was compared with the rate of oviposition of the beetles kept in confinement.

The relation between the curves representing temperature variation and oviposition record was very noticeable, and the mean daily temperature seemingly affects the progress of oviposition until well into the summer. The oviposition record of 16 beetles in 1912 shows 1,184 to have been the largest number of eggs deposited and 726 eggs per female the average for the series. In a series of experiments with 11 females collected from hibernation on December 20, 1911, and allowed to deposit eggs in the warm laboratory room during the winter and spring as high as 1,918 eggs were deposited by one female, the average number of eggs deposited being 913.

Relation of the Arizona wild cotton weevil to cotton planting in the arid West, B. R. COAD (*U. S. Dept. Agr. Bul.* 233 (1915), pp. 12, pls. 4).—This bulletin deals with cotton growing in Arizona in its relation to the boll weevil, a variety of which (*Athonomus grandis thurberiae*) has been found developing on a wild cotton plant (*Thurberia thespisoides*). Accounts relating to this pest by Cook (E. S. R., 29, p. 458), Pierce (E. S. R., 30, p. 56), Pierce and Morrill (E. S. R., 31, p. 350), and Coad (E. S. R., 31, p. 458) have been previously noted.

The author discusses the distribution of this weevil and *Thurberia*, the life history of the weevil on cotton in the South and on *Thurberia*, nature of damage to cotton, food preferences, the transfer to cotton, etc., and give descriptions of the weevil stages. While existing on the wild cotton plant in some of the mountains of southeastern Arizona, the weevil seems to be particularly concentrated in the ranges surrounding Tucson. The author points out that while its attack may be transferred from the wild cotton plant to cultivated cotton in the Santa Cruz and Rillito Valleys, its present habits are such that it would not injure cotton greatly, although its habits may be changed to a certain extent and more injurious ones acquired. "The present habits render it quite probable that the control of the Arizona form will be a very different problem from that of the cotton weevil and more easily solved. A careful watch should be maintained for the first appearance of the weevil on cultivated cotton in order that it may be combated successfully."

Notes on the life history of *Prospaltella perniciosi*, D. G. TOWER (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 422-432).—The author calls attention to the fact that *P. perniciosi*, which he previously described as new (E. S. R., 29, p. 459), is a true internal parasite, the larval forms living within the body tissues of the female San José scale except during the last part of the second larval stage, when the entire contents of the host are consumed by the larva, which then pupates in the empty skin of the scale.

While the number of eggs deposited by an individual has not been determined, the author reports having obtained 1,364 developed eggs from 20 females selected as they emerged, giving an average of 68 developed eggs apiece. By rearing parasitized scales of the first stage in the laboratory at temperatures varying

from 68 to 72° F., it was found that the parasites reached maturity in from 36 to 39 days, while the parasites in the second stage scales matured in from 19 to 23 days. The winter is passed as undeveloped and partially developed eggs in the bodies of the first and second stage scales, and the first larval stage also winters over in the second stage scales and also in the bodies of second stage larval parasites. It is stated that these second-stage larvæ are not arrested in their development by the second parasite within them until after they have completed their growth and passed their waste. Since older forms of the parasite, such as the second stage larva, pupa, and adults, have not been observed to winter over, it appears that dormant or winter spraying will kill the parasite as well as the scale.

The predaceous enemies of the scale, such as *Microweisia (Pentilia) misella*, are destructive to the parasite in all its stages of development except the adult stage.

On the capture of living insects by the cornfield ant (*Lasius niger americanus*), W. P. FLINT (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 476-478).—The author records observations made every night for nearly two months of the movements of the cornfield ant at Bloomington, Ill. It was frequently noticed that on warm nights when the ants were very active they would attack and kill many small insects that came near their nests.

Description of a new sawfly injurious to strawberries, S. A. ROHWER (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 479-481).—A new species which is the source of injury to strawberries in Iowa is described as *Empria fragaria*.

The economic status of the fungus diseases of insects, R. W. GLASER (*Jour. Econ. Ent.*, 7 (1914), No. 6, pp. 473-476).—A brief review.

Harvest mites, or "chiggers," F. H. CHITTENDEN (*U. S. Dept. Agr., Farmers' Bul.* 671 (1915), pp. 7, figs. 3).—This is a revision of Circular 77 of the Division of Entomology, previously noted (*E. S. R.*, 18, p. 559).

FOODS—HUMAN NUTRITION.

Air, water, and food from a sanitary standpoint, A. G. WOODMAN and J. F. NORTON (*New York, John Wiley & Sons, Inc.; London, Chapman & Hall, Ltd., 1914, 4. ed. rev., pp. V+248, pl. 1, figs. 16*).—In this, the fourth edition, the whole book has been carefully revised and the character of the treatment of certain parts has been radically changed to make it of more use in colleges and technical schools. Since the last edition, in 1909 (*E. S. R.*, 22, p. 366), "there have been distinct advances in analytical methods, and a changed point of view has brought about a somewhat different interpretation of results. This is particularly true with regard to the relation of air to health and comfort. . . . All of the discussion on air and water has been completely rewritten, as has the section on milk, the older methods revised, and numerous additions, to correspond with the latest practice, made. As in previous editions, these discussions are intended to be essentially elementary rather than exhaustive.

Progress in food chemistry, H. BECKURTS, H. FRERICHS, and O. BECK (*Jahresber. Unters. Nahr. u. Genussmitt.*, 23 (1913), pp. 192).—This publication contains a brief summary and digest of the more important additions to the knowledge of chemistry of food and nutrition during the year 1913. The subjects covered are general chemistry of foods and nutrition, milk, butter and margarin, cheese, eggs, fats and oils, meats and meat products, cereals and cereal products, fruits and fruit products, sugar, and beverages, both alcoholic and nonalcoholic.

Preservation of meat, A. GURINI (*Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 37 (1914), Nos. 15-16, pp. 669-678; 17, pp. 711-724; 18, pp. 764-782; 19, pp. 799-825*).—This article includes some analyses showing the composition of fresh and preserved meats.

Pork and pork fat and their use in the household, M. HERTER and G. WILSDORF (In *Die Bedeutung des Schweines für die Fleischerversorgung*, Berlin: Deut. Landw. Gesell., 1914, pp. 115-166, pls. 24).—In this article information of general interest is given regarding the cost of pork, methods of slaughtering, and its inspection and handling in the meat trade. The different cuts of pork are described and illustrated. The preserving and pickling of pork and pork products are also considered, together with the different ways in which the various parts of the animal may be utilized, and some information regarding the value of pork in the diet.

Composition of corn (maize) meal manufactured by different processes and the influence of composition on the keeping qualities, A. L. WINTON, W. C. BURNET, and J. H. BORNHANN (*U. S. Dept. Agr. Bul. 215 (1915), pp. 31*).—This bulletin reports the results of an investigation in which was studied the general composition of American table corn meal milled by different processes, but more especially the keeping quality of different types which had dried to different degrees and were stored in various localities. The composition of grits and by-products was also considered to some extent.

General information is given concerning the consumption of corn meal in its various forms in different parts of the country. The stone and roller processes of grinding corn and the various products of corn milling are briefly described.

Chemical analyses were made of samples taken from 41 mills located in 32 towns in 17 States. These samples were classified by the authors as follows: "Whole-kernel, stone-ground meal; bolted, ungerminated meal; degerminated, bolted, roller-ground meal ('cream meal'); and low-grade or 'standard' meal." The analytical data regarding these samples are reported in detail, but may be summarized briefly as follows:

"Whole-kernel meal at the time of grinding is the same in composition as the corn except in regard to moisture, but soon develops a greater acidity.

"Bolted, ungerminated meal contains less fiber than the corn, but no other general rule can be formulated owing to the variable conditions of manufacture.

"Degerminated, bolted meal contains less protein, fat, fiber, and ash, but more nitrogen-free extract than the corn.

"Low-grade ('standard') meal contains sometimes more and sometimes less of each constituent than the corn."

In experiments carried out to determine the effect of moisture upon its keeping quality, ten lots of degerminated, bolted, roller-ground meal, containing different amounts of moisture, were stored at Savannah and Chicago. The detailed results of these experiments are reported and are summarized briefly by the authors as follows:

"The lot containing 16.68 per cent of moisture showed an excess of acidity in 12 weeks, a loss of fat in 16 weeks, and a musty taste in 20 weeks. The lot containing 15.04 per cent of moisture only slightly exceeded the limit for acidity (30) in 24 weeks, and did not suffer in taste or appearance, while those with 13.41 per cent or less kept well in all respects up to the end of the experiment (24 weeks).

"Carload lots . . . with 15.73 per cent of moisture, showed an excess of acidity at Savannah in 8 weeks and at Chicago in 12 weeks, but did not suffer appreciably in quality. Highly dried meal with 9.86 per cent of moisture after 24 weeks showed a maximum acidity of only 21.8."

Studies of the comparative keeping quality of whole-kernel and degerminated meal showed the superior keeping quality of the latter.

From a consideration of the results of these experiments the authors draw the general conclusion that "degerminated, bolted meal containing not over 14 per cent of moisture and 1 per cent of fat, as determined by the method of the Association of Official Agricultural Chemists, properly stored should keep for 6 months; with a moisture content of 15 per cent it should keep 3 months. Schindler's limit for moisture, namely 13.5 per cent, obtained by drying in an open dish, corresponds to about 14.5 per cent by the method of the Association of Official Agricultural Chemists.

"Whole-kernel meal, like cream, should be produced locally and consumed soon after grinding; properly dried, degerminated meal, like butter, keeps well during transportation and long storage."

The use of rice flour in bread making, N. NOVELLI (*Gior. Riscoll.*, 5 (1915), No. 5, pp. 68-72).—General information and comparative analyses are given of bread made with 25 per cent of rice flour and several other kinds of bread.

Bitter and sweet cassava—hydrocyanic acid contents, A. E. COLLENS (*Bul. Dept. Agr. Trinidad and Tobago*, 14 (1915), No. 2, pp. 54-56).—Determinations were made of the hydrocyanic acid content of freshly dug roots, of those which had been removed from the ground for three days, of the liquid expressed from bitter cassava, and of the boiled roots.

The results of these experiments showed "that if sweet cassava is properly cooked either by boiling or roasting . . . no hydrocyanic acid is developed even on allowing to stand for one day. In the case of both bitter and sweet cassava if the roots are not properly boiled and are allowed to remain soaking in water for some time, there is a possibility of a small amount of hydrocyanic acid being developed."

Ash content of canned vegetables, with special reference to canned peas, AGNES F. MORGAN (*Jour. Home Econ.*, 7 (1915), No. 2, pp. 72-77).—The work of others is reviewed, and the results reported of experiments in which were studied the loss of mineral constituents of canned vegetables due to blanching.

"As compared with the corresponding fresh peas, the ash content of peas blanched and canned by the usual high pressure process was found to be 46.1 per cent less, that of peas blanched and canned by the standard home process 50 per cent less, and that of peas unblanched and canned by the standard home process 22.6 per cent less. All these percentages were calculated for the water-free substance.

"The percentage of extraction of P_2O_5 in each case is rather higher than the total salt extraction, indicating a special solubility of the phosphorus compounds.

"Inspection of two varieties of commercial canned peas shows a high total of salts in the liquor."

[Food and drug inspection] (*Ann. Rpt. Bd. Health Mass.*, 45 (1913), pp. VI+790, pls. 2).—A review of the work of the department of food and drug inspection for the year ended November 30, 1913, is given.

The report of the state analyst, H. C. Lythgoe, presents in detail the results of the examination of 9,727 samples of foods and drugs, of which 7,560 were of good quality. The work of the department also included the inspection of cold-storage plants and the examination of articles placed in cold storage. Data are given showing the results of this examination and the disposition of condemned cold-storage foods.

The report also includes a résumé of the inspection of slaughterhouses and dairies.

Ohio food and drug laws (*Columbus, Ohio: State, 1913, pp. 60*).—This compilation, prepared by the Agricultural Commission of Ohio, gives the text of acts regulating the manufacture and sale of foods, drugs, paints, oils, etc., sanitary inspection, and weights and measures.

Meat and food inspectors' examinations, G. T. BILLING and A. H. WALKER (*London: Sanitary Publishing Co., Ltd., 1914, 2. cd., pp. XII+180+23, figs. 8*).—This revised edition, which is intended for the use of those preparing for meat and food inspectors' examinations, contains model answers to questions set by the Royal Sanitary Institute and other examining bodies.

Selection of household equipment, HELEN W. ATWATER (*U. S. Dept. Agr. Yearbook 1914, pp. 339-362, pls. 4, fig. 1*).—In this article the author takes up a number of principles which should govern the selection of household equipment. Among other considerations emphasis is laid upon the importance of planning before buying; the consideration of necessity, convenience, and pleasure; and economy in cost and care. More detailed information is given regarding the choice and selection of permanent equipment, the finish of woodwork and walls, and the selection of furniture and household textiles.

The school lunch service, E. F. BROWN (*Dept. Ed. N. Y. City, Div. Ref. and Research Bul. 3 (1914), pp. 20*).—This pamphlet gives a résumé of the origin, development, and present organization of the New York School Lunch Committee. The mechanism of the service and the methods employed, together with the cost and nutritive value of the food supplied, are considered somewhat at length. Sample menus, including figures showing their fuel value and cost, are also given.

Memorandum on methods of providing meals for children in connection with public elementary schools and on dietaries suitable for the present circumstances, L. A. SELBY-BIGGE (*Bd. Ed. [London] Circ. 856 (1914), pp. 20*).—This pamphlet, issued by the Board of Education of London, considers somewhat at length the necessity for the feeding of school children under certain conditions, gives suggestions regarding its supervision, and enumerates a number of the problems involved in such work. It is stated that a good dietary can not only contain suitable quantities of nutritive and energy-producing material, but can be varied, palatable, easily digested, and obtained at reasonable cost.

Tables of meals are given which contain recipes for the preparation of the food, the amounts of the ingredients given being such that the meal will supply 100 children. Approximate cost data are given, together with supplementary notes on equipment of dining room and kitchen, and notes upon cooking. The meals described include four classes of 1-course dinners, namely, soup dinners, meat dinners, fish dinners, and cheese dinners. Tables are also given for 2-course dinners and for breakfasts and teas.

Prevention of beri-beri among Philippine scouts by means of modifications in the diet, W. P. CHAMBERLAIN (*Jour. Amer. Med. Assoc., 64 (1915), No. 15, pp. 1215-1220, fig. 1*).—This report, which supports the theory that beri-beri is a disease due to the ingestion of a diet deficient in some essential principle, gives the results of clinical observation and experience. Following the addition of beans or mongos to the ration and the substitution of unpolished rice for polished rice, beri-beri almost entirely disappeared among the scouts.

The metabolic relationship of the proteins to glucose, N. W. JANNEY (*Jour. Biol. Chem., 20 (1915), No. 3, pp. 321-350, figs. 8*).—From results of feeding experiments with laboratory animals (dogs), the author concludes in part as follows:

"Each protein produces a definite amount of glucose in the phlorizinized organism. The various yields represent 50 to 80 per cent by weight of the protein administered. These yields approximate the ratios which the gluco-

genetic amino acids of the proteins in each case bear to the total amino acids, as actually determined by hydrolysis. . . .

"The amounts of glucose yielded by the metabolism of proteins stand in no obvious relationship to their ability to promote growth. . . .

"Vegetable and animal proteins under optimal conditions are metabolized at the same rate in the animal organism. All the extra glucose and nitrogen are eliminated by the ninth hour after ingestion."

The influence of the plane of protein intake on growth, E. V. McCOLLUM and MARGUERITE DAVIS (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 415-428, figs. 12).—Laboratory animals (rats) were fed a ration consisting of dextrin, butter fat, and varying amounts of skim-milk powder, for which was substituted in a part of the experiments wheat protein, wheat embryo protein, and egg protein. A number of curves are given to show the influence of protein intake on growth.

The results of these tests may be summarized in part as follows: "The lowest plane of protein intake derived from milk which can maintain young rats without loss of body weight is 3 per cent of the food mixture. There is a progressive increase in the rate of growth with rations derived from milk, as the plane of protein intake is raised between 3 and 8 per cent of the diet. . . .

"For a time at least rats may grow at about half the normal rate when the protein is supplied by the wheat kernel to the extent of 6 per cent of the food mixture.

"Two and forty-five hundredths per cent of protein derived from desiccated egg is not sufficient to maintain young rats without loss of body weight.

"During six weeks a ration carrying but 4 per cent of protein from wheat embryo compares favorably with a similar plane of protein intake derived from milk powder, and is somewhat better than 6 per cent of protein from the entire kernel.

"This plan of experimentation [is believed to offer] a valuable method of comparison of the proteins from various sources, provided all deficiencies are made up by suitable additions."

The comparative nutritive value of certain proteins in growth, and the problem of the protein minimum, T. B. OSBORNE, L. B. MENDEL, ET AL. (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 351-378, figs. 10).—In continuation of previous work (E. S. R., 31, p. 558), relative to the importance of amino acids in maintenance and growth, the authors report further feeding experiments with laboratory animals (rats). The diet used contained protein-free milk and milk fat with varying amounts of casein, edestin, lactalbumin, and several other proteins.

It was found that growth could be facilitated or repressed at will by the addition or withdrawal of cystin from a diet containing 9 per cent of casein. With only 9 per cent of lactalbumin in the food, growth was about normal. This protein contains both lysin and tryptophan in relative abundance, which it is thought make up a more perfect balance in the proportion of the amino acid groups essential to nutritive efficiency.

It would seem from these and similar observations that the amino acid content of proteins is an index of the comparative values of these proteins as nutrients in growth. The required minimum of the protein lowest in its yield of any one amino acid essential to maintenance or growth may be expected to exceed greatly that of some other protein containing an abundance of the necessary amino acid.

Further observations of the influence of natural fats upon growth, T. B. OSBORNE, L. B. MENDEL, ET AL. (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 379-389, figs. 6).—In previous experiments (E. S. R., 31, p. 560) the authors have observed that if rats are given a ration consisting of isolated and purified pro-

tein, a carbohydrate like starch, protein-free milk, and commercial lard, they usually grow normally for about three months, but never attain their full size. A partial or complete cessation of growth which results in a decline of body weight occurs sooner or later, and ultimately ends in death if the diet is not changed. The authors found that if part of the lard were replaced by other natural fats recovery resulted.

The results obtained in the present series of experiments are summarized as follows:

"The failure of lard to promote growth in the same manner as do other natural fats (i. e., butter fat, egg yolk fat, cod liver oil) is not attributable to deteriorating changes arising from heat or chemical agents in the commercial manufacture of the product. Heating butter fat with steam does not destroy its growth-promoting efficiency.

"Beef fat also renders the inefficient diets used by us more suitable for producing growth in rats than does lard.

"When butter fat and beef fat are subjected to fractional crystallization from alcohol, the growth-promoting factor remains in the mother liquid or 'oil' fractions. The fractions containing the fats with high melting points are ineffective."

Purin metabolism of man.—III, The decomposition of purin compounds in the digestive canal, V. O. SIVÉN (*Pflüger's Arch. Physiol.*, 157 (1914), No. 11-12, pp. 582-586).—It was found by artificial digestion experiments that the purin compounds contained in bouillon were easily decomposed by cultures of *Bacillus coli*. It is concluded that the loss (about 50 per cent) which the exogenous purins undergo during their passage through the human organism occurs in the digestive canal, principally due to the action of the intestinal bacteria. See also former work (E. S. R., 29, p. 63).

The metabolism of vegetarians as compared with the metabolism of non-vegetarians of like weight and height, F. G. BENEDICT and P. ROTH (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 231-241).—Employing a unit respiration apparatus, investigations were carried out to study the metabolism of vegetarians and nonvegetarians, both male and female. In a discussion of the experimental data the authors conclude "that living upon a vegetarian diet for a longer or shorter period does not fundamentally alter the basic gaseous metabolism. . . ."

"The average respiratory quotient found with the 22 vegetarians (i. e., 11 men and 11 women) was 0.83, while the average quotient found with 132 individuals subsisting on a mixed diet (77 men and 55 women) was 0.81. This difference is slight and is wholly incompatible with the belief that vegetarians, when in the post-absorptive condition, have available any considerably larger proportion of easily combustible carbohydrate material than have nonvegetarians."

The metabolism of athletes as compared with normal individuals of similar height and weight, F. G. BENEDICT and H. M. SMITH (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 243-252).—In these experiments the authors studied the effect upon basal metabolism of abnormal amounts of protoplasm such as are present in the body of the trained athlete. The subjects of the experiments were divided into groups of approximately equal weight and height, each group including athletes and nonathletes. The average heat production per kilogram of body weight was for the athletes 26 calories and for the nonathletes 24.4 calories. The heat production per square meter of body surface was for the athlete 863 calories and for the nonathlete 807 calories.

From these experiments the authors conclude as follows: "Athletes have a somewhat higher metabolism, both per kilogram of body weight and per square meter of body surface, than do the nonathletes with whom we have compared them. . . .

"The greatly increased proportion of active protoplasmic tissue present in the trained, hardened athlete is alone sufficient to account for the increase in the metabolism, and . . . this is not only an absolute increase, but from the nature of the comparison the metabolism is likewise increased per kilogram of body weight and per square meter of body surface. It would thus appear that the increase in the metabolism noted with athletes points strongly toward the earlier conception that the catabolism of the body is proportional not to the surface of the body, but to the active mass of protoplasmic tissue."

A comparison of the basal metabolism of normal men and women, F. G. BENEDICT and L. E. EMMES (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 253-262).—In this investigation the metabolism of 89 normal men and 68 normal women was studied. The computed heat production for 24 hours per kilogram of body weight averaged 25.5 calories for men and 21.9 calories for women. From these observations the general deduction is drawn that the metabolism of men is from 5 to 6 per cent greater than that of women of like weight and height.

Factors affecting basal metabolism, F. G. BENEDICT (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 263-299, figs. 6).—In this paper the author draws general deductions from a large number of metabolism experiments, which have been made for various purposes, with a view to determining the most important factors affecting basal metabolism. These deductions may be summarized in part as follows:

"Unquestionably body weight plays an important part. In general, large bodies give off larger amounts of heat than smaller ones, but there is no direct relationship between the total body weight and the total heat production. . . .

"Careful analysis of metabolism measurements obtained on athletes, normal men and women, and normal and atrophic infants, leads to the conclusion that the metabolism or heat output of the human body, even at rest, does not depend upon Newton's law of cooling, and is, therefore, not proportional to the body surface. While certain disturbances in this supposed relationship between the heat production and the body surface may correctly be ascribed to errors in the formulas used for computing body surface, nevertheless the vast bulk of the evidence shows that the variations between metabolism and body surface are far outside of any possible errors in formulas."

The proportion of inert body fat and active tissue greatly affects basal metabolism, and on this basis is explained the greater metabolism of athletes as compared with nonathletes. "The apparent influence of sex, as brought out in the comparison of the metabolism of men and women, may also be attributed to the greater proportion of inert body fat in the latter, with a consequent smaller amount of active protoplasmic tissue."

The effect of height upon basal metabolism is "due without doubt to the fact that the taller individual has the larger amount of active protoplasmic tissue. All these variables deal directly with the mass of the heat producing organism; i. e., the amount of active protoplasmic tissue."

Another very important factor is the stimulus to cellular activity which is influenced by several factors. "One of these factors is age, and it has been noted that with the growing organism of youth there is a much greater cellular activity than with the adult, and a consequent higher metabolism. It has been brought out, however, that in old age there may be actual atrophy of protoplasmic material.

"Sleep has also been shown to have an influence upon the basal metabolism, the stimulus to the cellular activity being greater with an individual when he is lying awake than when he is asleep.

"Considerable fluctuations in the basal metabolism have been found from day to day not only with a fasting man, but with normal individuals studied over considerable periods of time. These variations could not logically be attributed to changes in body weight or body surface, and obviously there was no change in height. Even in the course of 24 hours the fasting subject was found to have three distinct metabolic planes, showing clearly a diurnal variation in the stimulus to the cellular activity.

"Still other factors considered as influencing the stimulus to cellular activity are prolonged fasting, the character of the preceding diet, and the after effects of severe muscular work.

"From the evidence gathered with the various subjects studied it is clear that the basal metabolism of an individual is a function, first, of the total mass of active protoplasmic tissue, and second, of the stimulus to cellular activity existing at the time the measurement of the metabolism is made. Apparently at present no law can be laid down that will cover both of these important variables in the basal metabolism of an individual."

A respiration apparatus for small animals, F. G. BENEDICT (*Jour. Biol. Chem.*, 20 (1915), No. 3, pp. 301-313, figs. 3).—A description is given of a modified universal respiration apparatus of the closed-circuit type, which was designed for the measurement of the carbon dioxide production and oxygen consumption of small laboratory animals. It is also provided with a device for graphically recording the muscular activity of the animal. The results are reported of test experiments with the rabbit and the guinea pig.

Corrections in bomb calorimetry, G. N. HUNTLY (*Analyst*, 40 (1915), No. 467, pp. 41-48).—This article, which is supplemental to an earlier one,^a gives numerous other corrections which are to be applied in bomb calorimetry.

ANIMAL PRODUCTION.

Animal husbandry (*Missouri Sta. Bul.* 131 (1915), pp. 466-469, figs. 2).—Notes on the following investigations are presented:

Age as a factor in animal breeding, by F. B. Mumford and L. A. Weaver.—The results seem to indicate that early pregnancy and lactation causes arrested development in the mother. Pregnancy itself did not cause retarded growth. The growth curves of young pregnant sows followed the same general direction as the growth curves of young nonpregnant sows when each was subjected to the same conditions of food, shelter, and exercise. The growth curves of young sows with suckling pigs, compared with the growth curves of nonsuckling sows of similar age and breeding, give evidence of the retarding effect of lactation on the growth.

Use of feed experiment, by H. O. Allison.—In this experiment comparing the influence of various planes of nutrition upon breeding cattle, no definite conclusions have been reached, but indications are that the higher the plane of nutrition the more food there is required for beef production.

Preparation of corn for fattening steers, by H. O. Allison.—Five lots of six choice 2-year-old steers each were fed a ration composed of corn silage, hay, cotton-seed meal, and corn prepared in various ways. The steers receiving finely ground corn chop made the highest average daily gain and the greatest

^a *Jour. Soc. Chem. Indus.*, 29 (1910), No. 15, pp. 919-921.

profit per steer. More beef and pork were produced from a bushel of corn by the lot which received broken ear corn. This lot produced the second highest profit per steer.

Forage crop rotations for pork production, by L. A. Weaver.—It was found that after deducting the gain put on by corn fed to hogs grazing on different forage crop plats, the returns per acre with pork at 7 cts. per pound were as follows: With rape, oats, and clover, \$47.04; rape and oats, \$44.10; rape in rows (cultivated), \$44.95; rape broadcasted, \$34.09.

Relative efficiency of pregnant mares for farm work, by E. A. Trowbridge, E. H. Hughes, and S. T. Simpson.—The results indicate that draft mares can produce healthy and normal foals and still do their share of ordinary farm labor. Mares with suckling foals show a greater loss in weight in the spring and summer seasons than do mares not suckling. Mares nursing foals make very rapid gains in weight after weaning.

Feeding wheat to fattening swine, by L. A. Weaver.—A ration composed of corn, wheat, and tankage 5:5:1, or of wheat and tankage 10:1, made very economical gains on swine. When wheat was fed in one of the above combinations more gain was produced than when it was fed alone or with corn only, and more gain was produced by corn alone or corn and tankage 10:1.

A study of the residual effects of forage crops for swine, by L. A. Weaver.—The first year's work indicates that there is but slight advantage in feeding hogs that have been previously on pasture, as compared to hogs that have been previously kept in a dry lot.

Self-feeders for fattening swine, by L. A. Weaver.—A slight advantage has been observed in feeding pigs by a self-feeder over the ordinary method of feeding.

Some factors affecting fetal development, J. M. EVVARD (*Proc. Iowa Acad. Sci.*, 20 (1913), pp. 325-330).—This is a progress report of work being carried on at the Iowa Experiment Station to determine the effect of the nutrition of the dam during the pregnancy period upon the developing fetus. Studies with five lots of 5 gilts each have been previously noted (E. S. R., 28, p. 574).

Three lots of 10 yearling sows each and four lots of 12 ewes each were also fed upon different feed stuffs with the following results:

Effect on offspring of feed fed pregnant swine and ewes.

Kind of dam.	Daily pregnancy ration.						Offspring record.						
	Corn.	Meat meal.	Clover hay.	Al-falfa.	Oil meal.	Si-lage.	Average number of off-spring born.	Average weight of off-spring born.	Vigor.				
									Strong.	Me-dium.	Weak.	Dead.	
	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>		<i>Lbs.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	
Sow..	4.97						9.2	1.85	41	35	20	4	
Do.	4.11	.500					10.1	2.42	85	5	5	5	
Do.	4.06				1.120		8.8	2.22	76	15	5	4	
Ewe.	.802		2.91				1.67	6.58	60	30	5	5	
Do.	.799			2.71			1.75	7.91	85	5	5	5	
Do.	.587		1.74			2.88	1.67	7.44	80	20	0	0	
Do.	1.021					4.72	1.33	8.36	81	19	0	0	

From this it is seen that the supplemented rations not only produced larger but stronger pigs at birth. Even though the carbohydrates were limited as in the meat-meal lots, the increase in protein and ash was such as to influence

markedly the size and strength of the newborn pigs. The meat-meal ration gave somewhat better results than where a vegetable protein supplement such as linseed-oil meal was allowed. It was noted that both meat meal and oil meal increased the coat as well as the color of the skin. The meat meal produced a larger bone than oil meal, and both of these surpassed corn alone.

Attention is called to the small number of offspring per ewe in the corn silage lot, which contributes largely to the increased size of the young. Where silage was fed in addition to clover the vigor and size of the offspring was increased, whereas alfalfa as compared with clover, being richer in protein and ash than clover, produced the strongest and largest lambs, even though there were more of them. It is stated that more recent experiments have shown quite clearly that cotton-seed meal added to corn and corn silage increases the strength as well as the size of the offspring.

On the variation in the growth of mammalian tissue *in vitro* according to the age of the animal, A. J. WALTON (*Proc. Roy. Soc. [London], Ser. B, 88 (1915), No. B 606, pp. 476-482, pl. 1.*)—The author concludes from his investigations that "growth of tissues *in vitro* affords a valuable means of investigation as to the effects of age upon growth. The tissues of young animals grow more rapidly and vigorously than those of adult animals. The plasma of young animals is a much less suitable medium for the growth of tissue *in vitro* than the plasma of old animals. The unsuitability of the plasma of young animals as a medium is probably due to the presence of an increased amount of some inhibiting substance."

The English rabbit and the question of Mendelian unit-character constancy, W. E. CASTLE and P. B. HADLEY (*Proc. Nat. Acad. Sci., 1 (1915), No. 1, pp. 39-42, figs. 6.*)—In breeding experiments with rabbits the authors disprove the idea of unit-character constancy, or "gametic purity." It is said that "if crossing is likely to produce considerable changes in the characters which it is desired to combine in a new race, it is evident that Mendelian crosses must be used judiciously and with caution by the practical breeder," and that "if unit characters are not constant, selection reacquires much of the importance which it was regarded as possessing in Darwin's scheme of evolution, an importance which many have recently denied to it.

Breeding of farm animals, M. W. HARPER (*New York: Orange Judd Co., 1914, pp. XVII+335, figs. 104.*)—This is a general treatise on animal breeding designed for the farmer, breeder, and student. It discusses the fundamental principles underlying animal breeding such as development, selection, variation, and heredity, together with the more practical phases of the work. An appendix contains tables giving data as to breeds and breeders' associations.

The jack bean (*Canavalia ensiformis*), F. BARNSTEIN (*Landw. Vers. Stat., 85 (1914), No. 1-2, pp. 113-122.*)—The composition of the jack bean (*C. ensiformis*) is reported as water 13.26 per cent, protein 31.51, fat 2.18, nitrogen-free extract 41.99, fiber 8.59, and ash 2.47. The coefficients of digestibility as determined in a 4-week test with sheep are given as dry matter 87.5 per cent, organic matter 88.6, protein 80.5, fat 72.1, nitrogen-free extract 99.1, and fiber 72.9. The starch value is estimated to be 63.7, with 18.69 per cent of digestible protein, making it somewhat lower in nutritive value than the common field bean. The sheep were fed 0.44 lb. of crushed beans per day without apparent injurious effects.

Beet residues for farm stock, J. B. LINDSEY (*Massachusetts Sta. Circ. 48 (1914), pp. 7.*)—A general discussion of the feeding value of dried beet pulp,

molasses beet pulp, and beet leaves, based in part on work previously noted (E. S. R., 30, p. 176).

Ensiling potatoes with a lactic acid culture, AHR and C. MAYR (*Illus. Landw. Ztg.*, 34 (1914), No. 86, pp. 737, 738).—Successful experiments are reported in ensiling steamed and raw potatoes when the material was inoculated with a lactic acid culture. The silage was fed to cattle, sheep, and swine with favorable results.

Factors affecting range management in New Mexico, E. O. WOOTON (*U. S. Dept. Agr. Bul.* 211 (1915), pp. 39, pls. 9, figs. 3).—This is a general résumé of range conditions in New Mexico. It is said that the present status of the stock raising industry in New Mexico is but one phase of the adjustment of the various industries of the State among themselves and to the physical environment. The topographic, climatic, and soil characters of the State restrict by far the greater part of its total area to the business of stock raising so long as the present agricultural methods continue. It is recommended that some form of range control be instituted which will prevent the present system of overstocking.

Meat production in the Argentine and its effect upon the industry in the United States, A. D. MELVIN and G. M. ROMMEL (*U. S. Dept. Agr. Yearbook* 1914, pp. 381-390).—A paper presented before the section on experiment-station work of the Association of American Agricultural Colleges and Experiment Stations and previously noted (E. S. R., 32, p. 12).

Meat production in Australia and New Zealand, E. C. JOSS (*U. S. Dept. Agr. Yearbook* 1914, pp. 421-438, pls. 4).—A report of a study of the conditions under which the meat and meat food products of Australia and New Zealand intended for entry into the United States are produced, slaughtered, treated, and shipped.

It is stated that stock raising comprises the leading industry in both Australia and New Zealand, the former exceeding all other countries in the number of sheep and the amount of wool exported. In Australia, where the production of wool rather than mutton has been in the past the chief aim of sheepmen, the Merino or fine-wool type of sheep predominates. In New Zealand considerable attention has been given to the breeding of sheep for meat production, with the result that trade reports show the Downs, Romney, Leicester, and Lincoln lamb carcasses of New Zealand are highly regarded in the European market. In New Zealand the government has lent considerable encouragement and aid in developing the live stock industry by fostering the raising of sheep and dairy cattle, searching out and opening up new markets, granting subsidies to steamship companies, etc.

The meat-inspection laws and regulations of Australia and New Zealand are briefly described.

It is said that Australia's beef exports have increased rapidly in recent years, there being at present a prospect of large dealings with the Pacific ports of the United States. Australian mutton is quite widely distributed also, although to a less extent than the beef. The beef trade of New Zealand is small compared with that of Australia, but the exports of mutton and lamb are in most years more than twice as large as those of Australia. In addition, these countries export large numbers of frozen rabbits and hares.

Raising the dairy calf, E. G. WOODWARD (*Nebraska Sta. Bul.* 149 (1915), pp. 3-16, figs. 8).—This bulletin gives information on the raising of a calf on skim milk, and other items of general management.

Three dairy steers were fed from birth up to about one year of age. Whole milk was fed for about 3 weeks. The grain consisted of a mixture of corn chop and ground oats 2:1. The results were as follows:

Results of feeding three dairy steer calves on skim milk.

Kind of calf.	Period fed.	Feed consumed.				Weight of calf.		Average daily gain.
		Whole milk.	Skim milk.	Alfalfa hay.	Grain.	Birth weight.	Final weight.	
	<i>Days.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>	<i>Lbs.</i>
Jersey.....	360	258	5,958	1,609	1,178	60	580	1.44
Holstein-Jersey.....	384	251	6,366	1,696	1,652	48	750	1.83
Grade Holstein.....	344	245	5,620	1,584	1,238	74	700	1.82

It is estimated that it requires 175 lbs. of whole milk, 2,700 lbs. of skim milk, 125 lbs. of grain, and 450 lbs. of hay, costing a total of \$12.88, to raise a calf to the age of six months when skim milk is used. Such a calf will weigh from 250 to 400 lbs., depending upon the size of the breed and the thrift of the calf. Whether or not it will pay to raise steer calves of the dairy breeds or the inferior dairy heifers for meat will depend entirely upon conditions. It is estimated that if the calf is raised on whole milk, shortening the milk feeding period to about three months, about 900 lbs. of whole milk, 250 lbs. of grain, and 600 lbs. of hay, costing a total of \$19, will be required to raise the calf to six months of age.

Feeding sour milk to young calves, T. E. WOODWARD (*Hoard's Dairyman*, 49 (1915), No. 7, pp. 248, 256).—As a result of experiments conducted by the Dairy Division of the U. S. Department of Agriculture, in which skim milk allowed to sour naturally was fed to 22 young calves of different breeds and at different seasons of the year, and sour whole milk fed to two calves, it was found that "in no case did the sour milk cause digestive disturbances, even when the change from the sweet to sour was made abruptly and with calves only a few days old.

"The sour milk is not so palatable as the sweet milk; some very young calves refuse to drink the sour milk, especially if the temperature of the milk is low. The calves made as rapid gains on sour skim milk as upon sweet skim milk, and seemed to do as well on a diet alternating between sweet and sour skim milk as upon either alone.

"Sour milk is not as satisfactory as sweet milk for winter feeding; it chills the calves, and some drink it reluctantly when the weather is cold. It seems, however, that any calf which drinks the sour milk readily will do well upon it even in cold weather. In warm weather sour skim milk gives as good results as sweet skim milk. These experiments indicate that the dairyman might just as well let the milk for calf feeding become sour during the summer months instead of going to trouble and expense to keep it sweet."

It is suggested that the milk for feeding calves should be allowed to sour quickly and be fed as soon as possible; otherwise there is danger of contamination with harmful bacteria.

Calf-rearing experiments in Hungary, G. KERÉKES (*Köztelck [Budapest]*, 24 (1914), No. 61, pp. 2172, 2173; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 11, pp. 1473-1475).—Calves were fed separated milk, the cream being replaced by rye flour at the rate of 4 to 5 oz. per gallon of separated milk. The mixture was thoroughly churned and

warmed to the temperature of fresh milk. The calves were fed whole milk until four weeks old, when a gradual substitution was made of the emulsion until eight weeks old. They were then fed entirely on the milk emulsion, with a gradual substitution of separated milk at three months of age, when the calves were receiving approximately 2½ gal. per head daily. The average weight at three months of calves fed in this manner was 297.5 lbs. per head, while calves fed whole milk weighed 248.2 lbs.; at four months the weights were 380 and 305 lbs., respectively.

Notes on degeneration in the teeth of oxen and sheep, J. W. JACKSON (*Ann. and Mag. Nat. Hist.*, 8. ser., 15 (1915), No. 87, pp. 291-295).—The author comments on the absence of the first lower premolar tooth in the jaws of oxen often found among animal remains. This feature is thought to be due to disuse, probably through change of food or habit under domestication.

The woolgrower and the wool trade, F. R. MARSHALL and L. L. HELLER (*U. S. Dept. Agr. Bul. 206* (1915), pp. 32, pls. 11, fig. 1).—The items discussed in this bulletin are present methods of disposing of wool by the growers, factors that determine the value of wool, wool grading, market grades, sorting wool, pounds of wool per pound of cloth, the need of improvement in handling American wools, how American methods of handling wool may be improved, and fundamental rules for the wool trade. A glossary of terms used in the wool trade is appended.

Suggestions from Australasia to American sheep raisers, F. R. MARSHALL (*U. S. Dept. Agr. Yearbook 1917*, pp. 319-338, pls. 2, fig. 1).—The American and Australasian attitudes toward sheep raising are compared, on the basis of a visit in 1914 to Australia and New Zealand, and suggestions given for the improvement of the manner of disposing of the wool clip and the breeding of sheep in this country.

It is said that the Australian's idea of what constitutes an economical wool-producing animal is governed not by the price per pound received for the greasy wool, nor by the weight of the fleece, but by the total value of wool produced per acre of land. The type of wool is closely associated with the type of sheep, and the type of sheep must be varied to withstand regional variations in altitude, temperature, rainfall, and vegetation. The general effort in Australia to-day is to produce a wool which, compared with what is aimed at by American woolgrowers, is decidedly longer and coarser. It is argued that the larger framed and stronger constituted sheep that produce this robust wool suffer less from heat, drought, and scant feed than do the smaller and less vigorous producers of ultrafine wool. The newer type also has fewer skin folds on the body and is easier to shear. This robust wool is lighter in oil than are the finer wools and possesses a whiteness and an attractive character not easy to secure when fineness is paramount. The gain in the amount of wool produced per acre by the robust-wooled sheep more than offsets the extra price that has commonly been paid in the markets for the very fine wools. Other claims for the robust wool are that it retains its character in bad seasons or in a hard country, that it is not so easily pulled off on bushes, and that it is less likely to shed from sheep in low condition or poor health.

Methods of preparing wool for market in Australia are deemed far in advance of those used in the United States. It is said that because of their poor preparation American wools bring less per pound than imported wools of similar character. This is substantiated by showing the results of sorting and scouring two lots of wool—one grown in Idaho, the other imported. What remained of the Idaho wool after sorting and scouring was considered

fully equal to the clean imported wool and was mixed with the imported lot for manufacturing, but had received 3.3 cts. per clean pound less than its actual value.

The adoption of the Australian system in preparing American clips for market is recommended. It would be necessary to allow selling agents to group together lots of similar wools from various clips to make up sufficiently large offerings to interest the buyers in the trade who prefer to buy in lots of 50,000 lbs. and upward. In time it is thought that buying agents would be more willing to buy in smaller lots in order to insure the continuation of the improvement.

Breaking and training colts, V. G. STAMBAUGH (*U. S. Dept. Agr., Farmers' Bul. 667 (1915), pp. 16, figs. 11*).—A general discussion.

Average and frequency curves, C. POTTS (*Dept. Agr. N. S. Wales, Farmers' Bul. 93 (1914), pp. 12, 13*).—The author demonstrated, by the use of average and frequency curves, that in the pens supplied for the egg-laying competitions for the past ten years "there appear to be two distinct families in each breed throwing true as regards egg-laying capacity, one of these families, aptly called the 'low-bred,' having a lower average egg-laying capacity than the other. While each family has a definite average egg-laying capacity, individual pullets will lay above or below that average.

"Examining the curves for three breeds it was shown that the high and low bred families are about equally balanced in the case of the White Leghorn; hence there should be scope for considerable improvement by careful selection. Further, the Leghorns exhibit indications of having a higher egg-laying capacity than any other breed. The low-bred family predominates in the case of the Black Orpingtons; hence improvement by selection has a great deal of bad material to dispose of. The possibilities of the high-bred family, however, show that they are worthy of more attention than they have so far received. In the case of the Silver Wyandottes the high-bred family predominates. The curve indicates that they could not attain the egg-laying capacity of either of the breeds mentioned above; still with the high-bred family predominating, it should be a matter of ease to establish a flock having a good average capacity for egg laying."

It was further demonstrated that "if a pullet of exceptionally high egg-laying capacity is chosen, it is more than probable that she belongs to the high-bred family, while it is doubtful whether a pullet of average capacity belongs to the low or to the high bred family; and, in all probability, she is a cross between the two. To establish the high-bred family it is essential to choose the breeders from the family of higher egg-laying capacity. It has been seen that the exceptionally good layer probably belongs to this family. However, it would appear to be unwise to breed from her; she is an exception, and her progeny, in order to maintain the average of the family, would be low layers by way of compensation. The best birds to breed from would be the true sisters and brothers of the exceptional pullet, and the hens should not be much above the average of the family."

Sex-linked inheritance in poultry, G. LEFEVRE (*Missouri Sta. Bul. 131 (1915), pp. 488, 489*).—In continuation of work previously noted (E. S. R., 31, p. 368) a Silver Spangled Hamburg male was crossed on an F_1 hybrid female (from Leghorn male \times Hamburg female), the resulting F_2 generation being spangled in both sexes. In mating an F_1 hybrid male and F_1 hybrid female (both from Hamburg male \times Leghorn female) the resulting F_2 generation gave spangled and nonspangled females, the males showing all degrees of spangling. In mating an F_1 hybrid male and F_1 hybrid female (both from Leghorn

male×Hamburg female) the resulting F_2 generation showed spangling and nonspangling in both sexes.

It is concluded that "a spangle factor is present in the Hamburg which is transmitted in a sex-linked fashion, but evidently the pattern is affected by other factors, as the spangling varies from a condition which is practically identical with that of the pure Hamburg to one in which the pattern is disturbed to a considerable degree, both in its purity and its distribution over the body."

In crossing a Black Bantam male and F_1 hybrid female (from Black male×Seabright Bantam female) the resulting F_2 generation showed a full cock-feathered condition, a hen-feathered condition, and an intermediate condition in the males. In crossing an F_1 hybrid male× F_1 hybrid female (both from Seabright male×Black female) the resulting F_2 generation showed a full cock-feathered condition in all the males. In crossing an F_1 hybrid male× F_1 hybrid female (both from Black male×Seabright female) the resulting F_2 generation showed the full cock-feathered, hen-feathered, and intermediate conditions in the males.

No conclusions are drawn, and it is proposed to continue these experiments.

Changes in the secondary sexual characters of Gallinæ, A. PÉZARD (*Compt. Rend. Acad. Sci. [Paris], 160 (1915), No. 7, pp. 260-263, fig. 1.*)—The results of experiments in ovariectomy with poultry indicate that spurs and the male plumage may be developed in the female, but that the turgid comb and the crow of the cock are characters peculiarly belonging to the male bird and do not accompany ovariectomy as do the other secondary sexual characters.

Sexual differentiation of pigeons' eggs (*Carnegie Inst. Washington Year Book, 13 (1914), pp. 117-119.*)—A brief account of the work of O. Riddle, who has shown that "in pigeons, which usually lay two eggs at a time, commonly one male and one female, eggs destined to produce males are smaller, and have higher water content and smaller energy content, than those that produce females." By the use of the bomb calorimeter it has been demonstrated "that eggs destined to become males contain less stored energy than eggs destined to develop into females. Whether the difference in energy content (however it may have arisen) is the cause of the difference in the eventual sex or whether it is induced by a certain difference in the unfertilized egg which determines the difference in storage metabolism is uncertain. There is reason for thinking that the ova of birds are of two kinds, those destined to produce males and those destined to produce females, and there is also evidence that the former contain a sex chromosome which the latter lacks. This difference in the chromosomal content of the eggs destined to be males and females, respectively, may therefore be the cause of the difference of energy content of the two kinds of eggs."

A study is being made to determine "whether a modification of the amount of yolk stored in the egg can control the sex of the resultant chick. One result secured is that when the female pigeon is subjected to alcohol vapor it lays smaller eggs than normal. Other substances used (phloridzin and urotropin) have caused a reduction in the fertility of the egg, but have not markedly altered its size."

It has further been found that "when two full sisters from such series are hatched from the two eggs of a single clutch the first hatched behaves in copulation as though it were a male. Also females hatched early in the season (the period when most males are produced) are more masculine in behavior than are their own sisters hatched late in the season. . . . If extracts from the ovary of a pigeon be injected into those females that are behaving like males, they

come to behave like females. Contrariwise, if testicular extract be injected into those females that are acting like females they come to act like males. . . . The sex behavior of a bird is probably determined by internal secretions from its sex glands carried to its central nervous system. On this hypothesis the quality of the internal secretions of the ovaries of birds that act like males must be different from those of birds that act like females. The effect of the injected extract may perhaps be regarded as superior to that induced by the natural secretion of the ovaries."

The Campines, edited by F. L. PLATT (*Quincy, Ill.: Rcl. Poultry Jour. Pub. Co., 1914, pp. 87, pl. 1, figs. 80*).—This treats of the history, care, and management of this breed of poultry.

The White Leghorn, P. B. HADLEY (*Jour. Heredity, 6 (1915), No. 4, pp. 147-151, fig. 1*).—This material has been previously reported from other sources (E. S. R., 30, p. 71; 32, p. 671).

Chickens: Milk feeding and its influence on growth and mortality.—Comparative study of the value of sweet and sour milk, L. F. RETTGER, W. F. KIRKPATRICK, and L. E. CARD (*Connecticut Storrs Sta. Bul. 80 (1915), pp. 28, figs. 17*).—This is a continuation of work previously noted (E. S. R., 31, p. 484). The former experiments demonstrated that the feeding of milk to young chicks has a most favorable influence on the growth and on the lessening of mortality of the chicks. It tends to prevent mortality from all causes, and if fed soon enough and for a sufficiently long period, greatly reduces the death rate caused by bacillary white diarrhea.

The later experiments demonstrated that sweet and sour milk are apparently of equal value in their relation to growth and mortality, and that the different degrees of souring do not alter the results of milk feeding. The combined results on the 2,250 chicks fed show that those which received the sour milk gained 0.26 lb. per ten chicks for each pound of total solids consumed; the chicks that were fed sweet milk made a corresponding gain of 0.25 lb., and those which were not given any milk, 0.2 lb. In the lots of chicks which had been infected with *Bacterium pullorum* the mortality percentage was in the case of the sour-milk-fed chicks 49, sweet milk 39, no milk 54, and with uninfected lots 17, 16, and 30, respectively.

It is concluded that the value of milk as a food for chicks does not depend upon any acids that may be present, nor upon any particular types of micro-organisms, but upon the natural constituents of the milk. It is said that when milk is supplied freely to chicks it is important that they have abundant exercise, otherwise they are subject to leg weakness. This applies more particularly to early hatched chicks that are brooded wholly or for the most part indoors. The feeding of sweet or sour milk to young chicks has not been found in any way injurious to the chicks. If the milk is clean and not too old, none but the most favorable results should accompany its use as a food for chicks. There is no preference in the choice of sweet or of sour milk, but it seems very desirable that the same kind of milk be supplied throughout the milk feeding period.

The poultry industry in New York State (*N. Y. Dept. Agr. Bul. 65 (1914), pp. 202-445, figs. 109*).—This bulletin includes articles on the various breeds of poultry, the breeding of poultry for egg production, incubation, brooders and brooding, rearing chickens, feeding for egg production, poultry house construction, poultry diseases, market egg problems, and other related topics.

The egg and poultry demonstration car work in reducing our \$50,000,000 waste in eggs, MARY E. PENNINGTON, H. C. PIERCE, and H. L. SHEADER (*U. S. Dept. Agr. Yearbook 1914, pp. 363-380, pls. 4, fig. 1*).—This is a popular review of work previously reported (E. S. R., 31, p. 570), describing the various grades of

eggs, their defects, and methods of remedying these defects. The work of demonstrating these facts to farmers and egg dealers in Kansas, Oklahoma, Texas, Arkansas, and Missouri is described.

Edible snails, E. W. RUST (*U. S. Dept. Agr. Yearbook 1914*, pp. 491-503).—This article gives a description of the principal edible species of snails and treats of their commercial production and the possibilities of the industry in the United States.

DAIRY FARMING—DAIRYING.

Dairy husbandry (*Missouri Sta. Bul. 131 (1915)*, pp. 471-473).—The following investigations are in continuation of previous work (E. S. R., 31, p. 370):

Silage investigation, by C. H. Eckles.—Little difference was found in the temperature of silage preserved in silos built of concrete, wood, or tile. The temperature of the silage rarely exceeds 100° F. unless the silage is deficient in moisture or air is present. There was found to be a wide variation in weight per cubic foot, depending upon the amount of moisture and probably upon the amount of grain in proportion to stalk. It was found that shock corn may be ensiled with good results if there is added an amount of water approximate to the amount of dry fodder used.

Factors influencing the normal composition of milk. The effect of cotton-seed meal and cotton-seed by-products, by C. H. Eckles and L. S. Palmer.—A marked superiority in the keeping quality of butter made from a ration containing cotton-seed meal was noted. The butter is firmer when cotton-seed meal is added. The character of the roughage fed, however, determines the effect of the cotton-seed meal in the ration to a considerable extent.

Factors influencing the development of dairy heifers, by C. H. Eckles, T. C. Reed, and W. M. Regan.—Two 6-months-old dairy heifers were started on a ration much below the normal in content of mineral matter; one received bone meal and chalk in addition. After a year's feeding on this ration typical symptoms of calcium shortage were observed. It was found possible to restore the animals to normal condition by increasing the calcium in the ration.

From the data at hand it appears that an animal receiving approximately one-half of the protein called for by the feeding standard is able to make a growth that is almost normal. This indicates that the protein required is considerably less than that generally recommended.

From measurements taken of calves and other growing animals in the station herd it appears from the data so far obtained that the different breeds follow the same curve with the exception that certain ones reach maturity quicker than others. It has also been found that the animal reaches maturity in skeletal growth very much quicker than it reaches maturity in weight. Holstein cattle reach their mature development of skeleton at the age of between four and five years, while they continue to increase in weight normally for at least two years longer.

A height measurement taken from the top of the shoulder blade has been found to be more accurate than one taken at the withers. This is due to the fact that certain fluctuations occur in the latter owing to the relaxation of certain muscles which attach on the chest and shoulder blades and serve to hold the body up. During periods of rest these muscles relax with a consequent decrease in height.

Development and present state of dairying in Sweden, E. HAGLUND (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 2, pp. 179-185*).—A general résumé of the dairying industry in Sweden.

It is said that the best known varieties of Swedish cheese are Swedish large-eyed cheese, which in type and appearance resembles the Swiss Emmental cheese, about 14 in. in diameter and 4 $\frac{3}{4}$ in. high; and Norrland whole-milk cheese with small eyes, very soft, with a slightly pungent taste, about 16 in. in diameter and 6 in. in height, and made both with and without spices (caraway and cloves). Småland shepherds' cheese resembles the preceding cheese, but is more pungent and compact and is never spiced. Besides these cheeses, imitations of most of the well-known Dutch and English cheeses are made.

A study of three thousand advanced register records (*Guernsey Breeders' Jour., n. ser., 7 (1915), No. 5, pp. 25-28, figs. 9*).—In a comparison of 1,500 records taken of Guernsey cattle between 1901 and 1911, and a like number taken between 1911 and 1914, it was found that the records showing less than 6,000 lbs. of milk per annum have decreased 49.6 per cent, and those from 6,000 to 8,000 lbs. 32.2 per cent. In the 8,000 to 10,000 lbs. division there has been a 9.1 per cent increase, in the 10,000 to 12,000 lbs. division 96.5, in the 12,000 to 14,000 lbs. division 181.9, and in the over 14,000 lbs. division 228.5 per cent. There has been a decrease in the number of records falling in the division of under 400 lbs. of milk fat, and increases in all the other divisions.

In a comparison as regards the percentage of milk fat in the milk it was found that very few records show less than 4 per cent. There has been a large increase in the 4 to 4.5 per cent division. This condition prevails to a lesser degree in the 4.5 to 5 per cent division, while in the divisions above this there is a decrease in the proportion of records in the second lot. However, a greater number of records fall in the 5 to 5.5 per cent division than fall in any other division. The average percentage of milk fat for the breed at the time these figures were compiled was 5.002.

Nearly as large a proportion of records is made by the 2-year-old heifers with first calf as by the older cows, and while the proportion of aged cows has slightly decreased in the second lot of records, that of the 2-year-olds has slightly increased.

Champion cows of each breed (*Hoard's Dairyman, 49 (1915), No. 19, p. 700*).—The names are given of the cows of each breed holding the highest semi-official yearly records in their several classes, corrected to May 1, 1915.

Rations for dairy stock, J. B. LINDSEY (*Massachusetts Sta. Circ. 50 (1915), pp. 8*).—Some principles of feeding dairy cattle are discussed, and suggestive rations are given.

Feeding dairy cows cassava meal, J. E. LUCAS (*Ann. Sci. Agron., 4. ser., 3 (1914), No. 7-12, pp. 337-342*).—It is concluded that cassava meal when used as supplementary feed with a basal ration of sugar beets, chopped straw, alfalfa hay, and wheat bran exerted a favorable influence on both the milk yield and the fat content, being more desirable in this respect than gluten meal.

Influence of grazing and of dry-stall feeding on milk, K. BRUNOVSKY (*Moloch. Khoz. i Skotov., 13 (1914), No. 38, pp. 791-794; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 2, pp. 277, 278*).—A cow was fed for 20 days as follows: The first four days the whole time in a meadow; the next four days half the day in the stable where she was fed 11 lbs. of meadow hay; the third four days in the stable, 22 lbs. of hay being fed; the fourth four days like the second; and the fifth like the first.

It was found that while grazing the cow yielded 20.3 lbs. of milk per day and when stall fed only 16.3 lbs. The fat percentage increased when the cow was transferred from the meadow to the stall from 3.7 to 4.05.

The relation of the quality of proteins to milk production, E. B. HART, G. C. HUMPHREY, ET AL. (*Jour. Biol. Chem., 21 (1915), No. 2, pp. 239-253, figs. 4*).—

The authors present data on the comparative efficiency for milk production of the proteins of milk, corn, and the wheat grain.

It was found that "on a nutritive ratio of 1:8, equivalent to about 7 per cent of digestible protein and 9 to 10 per cent of total protein, positive nitrogen balances were maintained with milk proteins for the production of as high as 35 lbs. of milk per day, but negative balances resulted when the proteins were derived from the corn or wheat grain. During the negative nitrogen balances increased tissue autolysis resulted, and for a brief time at least there was no decrease in the milk protein or milk solids elaborated.

"The results indicate clearly that the quality of the proteins is an important factor in maintenance and production, and that the synthetic powers of the mammary gland will not compensate for deficiencies in protein structure. The fact that negative balances were observed on the 1:8 nutritive ratio of corn or wheat proteins explains the results of experience which has wisely dictated a narrow nutritive ratio for milk production. The narrow ratio, of course, may not be so necessary when we learn with what efficiency the commercial protein concentrates may supplement a basal group of proteins like those of corn, oats, wheat, alfalfa, etc. . . .

"Milk proteins had an efficiency for milk production and tissue restoration of about 60 per cent, while the corn and wheat grain proteins showed an efficiency of 40 and 36 per cent, respectively. These results were obtained under experimental conditions requiring a roughage of low nitrogen content."

The cost of milk production, H. A. HOPPER and F. E. ROBERTSON (*New York Cornell Sta. Bul.* 357 (1915), pp. 135-162, figs. 6).—From a study made of the costs incident to milk production for 834 dairy cows with full year's records in 53 dairy herds in Jefferson County, N. Y., it was found that 7 of the 53 herds, comprising 97 cows, were kept at a loss of \$1,335.71. On the basis of net cost and actual receipts, 161 cows, or 19 per cent of the total number, caused a loss to their owners of \$1,799.87, or \$11.18 per cow. The average production was 6,621 lbs. of milk and 241 lbs. of milk fat. The milk was produced at a net cost of 1.21 cts., and the milk fat at 33.3 cts. per pound. The average selling price of the milk was 1.52 cts. per pound, and the net profit per cow was \$20.39. The net cost per cow was \$80.24 and the receipts were \$100.63. The average cost of feed per cow was \$51.57, and the labor cost \$23.12. The average cost of delivering 100 lbs. of milk 2.14 miles was 11.7 cts. The profit from cows yielding 10,000 lbs. of milk a year was 51 per cent greater than from those yielding 6,000 lbs.

[Second and third reports] on the cost of food in the production of milk in the counties of Kent and Surrey (*Jour. Southeast. Agr. Col. Wye, No. 22* (1913), pp. 19-160).—The work noted in the second report, by G. H. Garrad and J. Mackintosh, is similar to that previously reported (E. S. R., 25, p. 679). In the third report, by G. H. Garrad, extensive data are given on the cost of feed in the production of milk in England—about 6½d. (15.8 cts.) per gallon, exclusive of labor and other charges.

It is suggested that cows should be fed according to the yield of milk they give. If they are already getting a liberal feed, it is not possible to increase materially the yield of milk by extra feeding, at least not sufficiently to pay for the increased cost of feed. The records show that the cost of feed per gallon of milk is much lower for a 4 or 5 gal. cow than it is for a 2 or 3 gal. cow, the reason assigned being that the maintenance ration required for either cow is practically the same, while the feed required for the higher-producing cow is not proportionately higher in cost.

Milk and cream (*Maine Sta. Off. Insp.* 67 (1915), pp. 9-28).—Analyses are given of samples of milk collected during the months of October, November, and December, 1914. A discussion of the results by A. M. G. Soule is appended.

Condensed milk, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 304 (1915), pp. 27).—Analyses are given of condensed milk.

Evaporated milk, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 305 (1915), pp. 19).—Analyses are given of evaporated milk.

Devonshire "clotted" cream, W. SADLER (*Rev. Gén. Lait*, 9 (1914), Nos. 20, pp. 457-466, pl. 1; 21, pp. 481-489).—This article describes the method of making clotted cream, a dairy product of Devonshire and Cornwall, England.

It is said that in the production of clotted cream, milk is placed in shallow pans and allowed to remain in a cool room for the cream to rise. The pans are then heated over a hot water stove, and after the heating is completed, are placed in a cool room until the contents of the pans are sufficiently cooled, after which the cream is skimmed off and is ready for sale.

The practice has been to add a small quantity of water to the milk before setting the pans for the cream to rise. The author finds, however, from his experiments that this is not desirable, since it does not add to the actual weight or the percentage of fat in the cream, and the cream so produced does not possess the keeping qualities of similar cream raised from normal milk.

The principal and most recent applications of bacteriology to the dairy industry, G. FASCETTI (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 2, pp. 168-179, pl. 1).—This is a résumé of the results of experiments in the use of selected ferments in the cheese-making industry.

It is said that the pure cultures of lactic ferments, cocci, or bacilli, according to the type of cheese, when added to raw milk have given results which have led to their adoption in practical cheese factories, especially for the elimination of the principal and most frequent defects in the products.

The problem now confronting the bacteriologist is to determine which of the typical forms of lactic ferments at present known are to be used and with what precautions. Such information is necessary in developing the process of manufacturing cheese from pasteurized milk, which is said to be still enveloped in uncertainty.

A bibliography of 29 references is included.

The part played by micro-organisms in the ripening and in the production of the pungent flavor of Brindza, the ewes' milk cheese made in Hungary, O. GRATZ and K. VAS (*Kisérlet. Közlem.*, 17 (1914), Nos. 3, pp. 347-394; 4, pp. 635-644; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 12, pp. 1674, 1675).—Bacteriological tests were made, at intervals of from four to six weeks for six months, of five samples of fresh Brindza cheese.

It was found that the microflora varied, probably due to the want of cleanliness in handling ewes' milk, the use of bad rennet, and contamination. It is said that there is no cheese with so high a germ content as Brindza even though after it is made and during storage the multiplication of micro-organisms ceases. Most of these are lactic bacteria, although not so large a percentage as in other cheeses. The large majority of accidental micro-organisms are probably introduced during the process of manipulation. These soon disappear, the streptococci and cocci dying much sooner than the lactic bacilli. The accidental micro-organisms do not take part in the ripening of the cheese, because the conditions do not favor either their development or the activity of their enzymes. The lactic enzymes cause the ripening, although the enzymes of the rind of the curd ball also play an important part in the ripening process.

It is said that the origin of the piquant flavor of some ewes' milk cheeses is usually in a decomposition of the fatty matter, and in exceptional cases butyric fermentation. This decomposition is not caused by the bacteria attacking fatty matter, but to enzymes, the most important being the lipase of *Oidium lactis*. If the outside of the curd balls (rich in butyric ferments and on which *O. lactis* is always present) and the fat layer under this outside (in which the enzymes are found) are not carefully removed when the cheese is worked up again, these come in contact with the whole of the kneaded paste and communicate a pungent flavor to the cheese.

Strongly flavored Brindza has a pale orange color, is dry, subject to crumbling, strong smelling, and never turns moldy. Sweet Brindza is of normal consistency, but becomes sticky and moldy if it is not kept hermetically closed.

Part 2 of the paper describes "some new species of micro-organisms found during the research on the flora of Brindza and the part they play in the ripening and production of the special flavor of this cheese. Considering the various properties of these bacteria observed during their culture and their biochemical action, they do not resemble any of the micro-organisms known so far to the literature of bacteriology. These new species are *Bacterium saponificans*, *B. adipis*, *B. rufum*, *Bacillus gravidus*, *B. submergens*, *B. exilis*, *B. cerasinus*, *B. parabutyricus*, and *B. indolicus*."

Production of a nutritive beverage from skim milk, R. EICHLÖFF (*German Patent 280,446, June 14, 1913; abs. in Jour. Soc. Chem. Indus., 34 (1915), No. 9, p. 507*).—"The milk is heated with an acid, e. g., hydrochloric acid, to sterilize it and invert the lactose, and is then submitted to the simultaneous action of peptonizing enzymes and fermentation organisms; for example, trypsin and yeast. The fermented liquid is sterilized by heat, filtered, and evaporated to the desired consistence."

VETERINARY MEDICINE.

[Report of the veterinary department], J. W. CONNAWAY ET AL. (*Missouri Sta. Bul. 131 (1914), pp. 486-488*).—*Study of contagious abortion*.—The complement fixation test was found to be a very reliable method for detecting animals infected with the *Bacillus abortus*, confirming results obtained at other experiment stations. In old infected herds the percentage of reactors varied from 60 to 90 per cent. With the methylene blue treatment, judging from the reports sent in by owners of herds under experiment, good results are being obtained. "In one herd where the loss from abortion in heifers carrying first calf averaged 58 per cent during the preceding two years the loss was reduced to 28 per cent—apparently from the methylene blue treatment."

Tuberculosis of cattle and swine—transmission of same.—Post-mortem examinations made during the past year indicated that tuberculosis is not so easily transmitted from sows to their offspring as from cows to calves and cows to pigs. This is probably due to the destruction or mitigation of the virulence of the tubercle bacilli in infected swine by the prolific fat production of that animal. This may throw some light on the question of the value of fat-producing foods in treating tuberculosis in man.

A study of internal parasites of swine and the efficiency of various vermifuges.—The condition of the infested animal is not deemed a reliable guide to the extent of parasitic infestation. "The diagnosis in some animals is readily made by noting the passage of worms. In others the presence of worms was detected only by finding ova in the feces by microscopic examination; and in other hogs, but slightly infested, the presence of worms was detected only by post-mortem examinations. When worms were present in large numbers, all

the recognized vermifuges were effective in expelling the greater number of the parasites, but nearly all the 'remedies' failed to expel all the worms. The most effective vermifuges tried in the experiments were turpentine, iron sulphate, copper sulphate, santonin, tobacco, and areca nut. Copper sulphate was found to be the most efficient in expelling the thorn-headed worm. Each experimental animal was kept in a separate pen during the experiment and was slaughtered to determine the efficiency of the vermifuge administered."

Experiments on complement fixation—hog cholera.—The blood sera of swine were found hemolytic for the red blood cells of one experimental horse, one goat, and two cows, but not for a third cow (No. 3) which was a reactor to tuberculin. "Hemolysis occurred whether the blood serum used was from normal hogs susceptible to cholera, hogs affected with acute cholera, or from hogs hyperimmunized to cholera.

"In the attempts to prepare an 'antigen,' extracts were made from the blood of six pigs suffering from the acute hemorrhagic type of cholera: six alcoholic extracts and six extracts with normal saline solution were used. The alcoholic extracts prevented hemolysis, but check experiments showed this to be due to the alcohol and not to an 'antigenic content' of the blood. The normal saline extracts, from blood, also failed to show the presence of a deviating antigen."

Separate saline extracts made from the spleen of six virus pigs failed to prevent hemolysis. Saline extract prepared from the spleen of virus pigs gave a distinct deviation with the erythrocytes of cow No. 3 and with the blood serum of a hog hyperimmunized to both the filterable virus and *B. suispestifer*. In quantities of 0.01 to 0.02 cc. of the spleen extract negative results were obtained from the sera from other immune hogs and from hogs suffering with acute cholera. The positive deviation obtained with the serum of the hyperimmunized hog might have been caused by the *B. suispestifer* antigen and not by the filterable virus antigen. "Some further tests are to be made with the serum from this hog and cultures of *B. suispestifer*. Extracts from kidneys of 'virus pigs' failed to show any 'deviating content.'"

Studies from the Rockefeller Institute for Medical Research (Studies Rockefeller Inst. Med. Research, 20 (1915), pp. 591, pls. 32, figs. 25).—Reprints of papers on work done at the Rockefeller Institute or under grants therefrom. The topics dealt with are pathology and bacteriology, physiology and pharmacology, chemistry, experimental biology, and contributions from the Hospital of the Rockefeller Institute.

Some diseases, whose etiology is unknown, discussed in the light of the vitamin theory, R. REINHARDT (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), Nos. 37, pp. 645-647; 38, pp. 657-661).—Amongst the diseases discussed are polyneuritis gallinarum, trembles in sheep, and paralysis of the vestibular nerve in pigeons. See also a previous note by Funk (*E. S. R.*, 32, p. 578).

Some important animal parasites affecting Ohio live stock, D. C. MORE (*Ohio Sta. Bul.* 280 (1914), pp. 23-52, figs. 21).—This introduction to the subject calls attention to some of the animal parasites prevalent in Ohio and control measures therefor. A bibliography of 17 titles relating to the subject is included.

A revised check list of the animal parasites of domesticated animals in India, S. H. GAIGER (*Jour. Compar. Path. and Ther.*, 28 (1915), No. 1, pp. 67-76).—A revision of a check list previously noted (*E. S. R.*, 22, p. 791).

Abderhalden's protective ferments, C. BRAHM (*Ztschr. Angew. Chem.*, 27 (1914), No. 60, Aufsatzteil, pp. 464-466).—A discussion of the different protective ferments and their value for diagnosing disease.

About the nature of the meiotagmin reaction with malignant tumors, G. IZAR (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 21 (1914), No. 1-5, pp. 301-308).—The author concludes that the sera from subjects affected with malignant growths have a lesser surface tension reducing power in enveloping certain fatty acids than the sera from normal subjects. A number of facts elicited seem to point to the belief that this is dependent upon the increased content in the tumor sera of lipoids or lipid-fixing substances.

Abderhalden's reaction and its relation to the presence of antithrombin in the blood, H. DE WAELE (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 21 (1914), No. 1-5, pp. 83-90).—The injection of a hydrolyzate consisting chiefly of peptones and amino acids yielded defensive ferments for the proteins from which the peptones and amino acids were obtained. Proteins administered per os also stimulated the development of protective ferments. Abderhalden's reaction apparently stands in exact relationship to the antithrombin phase. The nature of the relationship will be considered in a future communication.

Preparation and standardization of vaccines, antitoxins, and serum, C. P. FITCH (*Cornell Vet.*, 4 (1915), No. 4, pp. 171-183).—A general discussion of the topic.

The pharmacological action of some serum preservatives, C. VOEGTLIN (*Pub. Health Serv. U. S., Hyg. Lab. Bul.* 96 (1914), pp. 87-119, pls. 2, figs. 13).—The effect on animals of normal serum free of preservative and containing trikresol (0.1, 0.25, 0.3, and 0.5 per cent) phenol serum (0.1, 0.25, and 0.5 per cent), formaldehyde serum (1:1,000) and chloroform serum (saturated) was studied.

"From the experiments described it would seem that chloroform when added to serum, even to the point of saturation, is not capable of imparting to the serum a degree of toxicity which could be compared with that obtained on mixing serum with phenol and trikresol (0.25 and 0.5 per cent). Practically the only effect which could be produced by the subdural injection of chloroform serum is the result of an increase in intracranial tension. With the use of the gravity method such results are not very apt to follow and it seems very doubtful that they occur at all. We, therefore, strongly suggest that chloroform be used as a preservative for antimeningitis serum. It is well recognized that serum preserved with chloroform after long standing will show a cloudiness which is probably due to the partial precipitation of the serum proteins. This fact, however, does not alter the efficiency of such a serum in the treatment of the disease."

The gravity method is given preference over the syringe method.

Studies on complement action; with special reference to the fractioning of complement by means of ammonium sulphate, C. H. BROWNING and T. J. MACKIE (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 21 (1914), No. 1-5, pp. 422-446).—In these experiments the hemolytic complement of guinea pigs was fractionated with ammonium sulphate.

In the fractionation of complete serum the pseudoglobulin fraction was found in some cases to contain the entire complement, whereas in others it was necessary to add albumin to develop the complement action of the native serum. Albumin and euglobulin when used together added some complement action, but when used separately no action whatever. In the fractionation of the middle and end portion by ammonium sulphate the entire euglobulin and a little pseudoglobulin were found in the middle portion. The end portion contained the entire albumin and the greater amount of pseudoglobulin. The pseudoglobulin was divided into two fractions, one of which was inactive but when mixed with its other component exerted a stronger complement action. The

various globulin fractions possessed in varying amounts the activity of the third component (Ritz's). The albumin of guinea-pig serum was inert.

In the article the various theories on the constitution of the complement are discussed, and the earlier view of the authors in this connection, viz. that complement action is a complicated process, is considered correct. Serum-silicic acid hemolysis is deemed dependent upon the hemolytic complement of the serum. Definite parallelism exists between the toxic action of various sera and blood corpuscles sensitized with immune bodies, or silicated. Treatment of a mixture of serum and silicic acid with carbon dioxide yields a precipitate which contains the entire cobra venom inactivating powers possessed by the serum.

The fraction (precipitate) when tested against blood loaded with immune bodies indicates the presence of only the middle portion.

The hemolysis stimulating action of serum on mixtures of various di- and tri-phenylmethane coloring matters, brilliant green, etc., is not dependent upon complement.

Dialysis of native sera against hydrant water and dialysis of the serum remaining after precipitation with ammonium sulphate results in a decrease in deviability of complement without affecting the hemolytic powers of the serum. This is said to indicate that hemolytic power and deviability are two different functions of complement-holding serum. Frozen complement retains its hemolytic titer and deviability for many weeks.

The method is effective for obtaining standard complement.

Investigations of the nature of anaplasmas, E. C. DIAS and H. DE B. ARAGÃO (*Mem. Inst. Oswaldo Cruz*, 6 (1914), No. 3, pp. 231-249, pls. 2).—The authors' investigations led them to conclude that the Anaplasma are not protozoans, but products of degeneration of erythrocytes. What has been described by Theiler as anaplasmosis is considered by the authors a clinical form of piroplasmosis. The anaplasmosis of mammals is ascribed to different causes.

A bibliography of 37 titles is included.

The status of bacilli from fish meal which give a positive Ascoli reaction, M. ZINGLE (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 2, pp. 131-134, fig. 1).—The growth in bouillon and negative results with experimental animals led the author to conclude that the organism in the fish meal examined was the pseudoanthrax bacillus, notwithstanding its close relation to the anthrax bacillus as indicated serologically. The conclusions agree with those of Pfeiler and Drescher (*E. S. R.*, 30, p. 682).

Investigations of foot-and-mouth disease, LOEFFLER (*Amer. Jour. Vet. Med.*, 10 (1915), No. 6, pp. 381-388, 410, 428, 429, figs. 2).—This is a general discussion with a review of recent work.

Foot-and-mouth disease, its nature, cause, and treatment, compiled by J. C. SMITH (*Saskatchewan Dept. Agr., Live Stock Branch [Pamphlet], 1915, Apr.*, pp. 7, figs. 2).—A popular account.

An improved method for the detection of mange acari, A. L. SHEATHER (*Jour. Compar. Path. and Ther.*, 28 (1915), No. 1, pp. 64-66).—The method here described is based upon the maceration of acari through boiling in a 10 per cent solution of caustic potash for a period not longer than 10 minutes. The material is then centrifuged, water added, and the sediment examined. It is stated that the method is not destructive to the eggs of mange parasites and that on more than one occasion when acari were not discoverable it has been found possible to arrive at a diagnosis by the detection of eggs.

The relapse in piroplasmosis, M. CARPANO (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 74 (1914), No. 5-6, pp. 482-487, figs. 2).—The author describes a typical case of relapse in the donkey brought about by a decreased resistance.

Piroplasmosis of Rhodesian sheep, as observed by Bevan, C. M. WENYON (*Jour. Compar. Path. and Ther.*, 28 (1915), No. 1, pp. 60, 61).—This article relates to a sheep which suffered from a double infection of anaplasmosis and piroplasmosis. Reports by Bevan of the occurrence of piroplasmosis in sheep have been previously noted (E. S. R., 27, p. 482).

Laboratory studies on tetanus, E. FRANCIS (*Pub. Health Serv. U. S., Hyg. Lab. Bul.* 95 (1914), pp. 73, figs. 2).—Studies reported herein were on the conditions surrounding tetanus spores artificially implanted into vaccine virus, the behavior of tetanus spores injected subcutaneously into guinea pigs and white mice, and miscellaneous observations upon tetanus.

Antigenic properties of various strains of East African trypanosomes, C. SCHILLING (*Ztschr. Immunitätsf. u. Expt. Ther.*, I. Orig., 21 (1914), No. 1-5, pp. 358-365).—Old laboratory strains of nagana trypanosomes are, generally speaking, deemed of little value for preparing immune antigen outside of the animal body. Strains obtained in East Africa were found to be inferior antigen stimulators.

The effect of daylight and drying on the human and bovine types of tubercle bacilli, L. FINDLAY and W. B. M. MARTIN (*Brit. Med. Jour.*, No. 2820 (1915), pp. 110, 111).—To account for the absence of aerial infection of man by the bovine type of bacillus, the authors sought to determine whether atmospheric influences, especially desiccation and daylight, are more deleterious to the bovine than to the human type. Three different kinds of experiments were made, as follows:

"(1) *Effect of desiccation alone*.—Weighed amounts of cultures, four weeks' growth, were placed in small sterile test tubes, loosely plugged with cotton wool, and kept in a dark, well-ventilated cupboard. Under these circumstances definite desiccation occurred. Emulsions were finally made in salt solution and amounts equivalent to 0.01 mg. of moist culture were injected intravenously into rabbits.

"(2) *Effect of diffuse daylight alone*.—For this purpose cultures, five weeks' growth, sealed with paraffin to conserve water of condensation, were exposed at the window. After desired intervals weighed quantities of growth were removed, emulsified, and injected as before.

"(3) *Effect of diffuse daylight with simultaneous desiccation*.—Weighed quantities of cultures, four weeks' growth, were exposed at the window in small sterile test tubes loosely plugged with cotton wool. Desiccation rapidly occurred. At intervals emulsions were made and injected as before."

The bovine type of bacillus was found to be distinctly more susceptible to the effects of daylight and drying than the human type. This difference between the types may in part explain why aerial infection with the human type is the more frequent.

Histological studies on serous tuberculosis of bovines, E. JOEST and V. MARJANEN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 1, pp. 1-38, pls. 4, figs. 11; *abs. in Berlin. Tierärztl. Wchuschr.*, 30 (1914), No. 33, p. 602).—The authors find that in every case of serous tuberculosis in bovines there are produced nonspecific inflammatory new formations. These later become infected with tubercle bacilli and result in the formation of pearl nodules.

The significance of fowl tuberculosis for the pig, M. CHRISTIANSEN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 14 (1913), No. 6, pp. 323-340).—The investigation involved the examination of 118 pigs. The pig is considered highly receptive to avian tubercle bacilli, and an infection from this source is noted frequently. Views relative to the determination of avian tuberculosis to swine must accordingly be changed.

Organ tuberculosis in pigs caused by the avian type of tubercle bacillus, M. CHRISTIANSEN (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 16 (1915), No. 4, pp. 264-274, figs. 2).—The new investigations have confirmed those reported above, inasmuch as avian types of tubercle bacilli were noted in the organs having a typical appearance. Giant cells were noted in the tuberculous processes. According to this, the finding of giant cells does not indicate that the tuberculosis is not caused by the avian type of bacillus. They were found in all mesenteric tuberculous processes, and in every case they were of the avian type.

The iodine content of tuberculous tissues, P. A. LEWIS and R. B. KRAUSS (*Jour. Biol. Chem.*, 18 (1914), No. 2, pp. 313-317).—"Tuberculous tissue derived from animals to which no iodine preparation has been knowingly administered may contain amounts of iodine very appreciably higher than normal control tissue of the same animal. While it is quite probable that tuberculous tissue in animals treated with iodine products may store up iodine, this has been by no means clearly shown in any experiments so far reported. The highest figures for the tuberculous tissue of untreated animals in our experience may equal the highest figures of those reported by others as evidence for the localization in the tissue of iodine intentionally administered."

A note on the use of purified antigen of Besredka in the serum diagnosis of tuberculosis, J. BRONFENBRENNER and J. ROCKMAN (*Biochem. Bul.*, 3 (1914), No. 11-12, pp. 375, 376).—In some previous work it was found that when Besredka tuberculin was used as antigen seemingly specific results were obtained with the sera of tuberculous subjects by the complement fixation test. The fact that the antigen contains lipins (derived from the culture medium) allowed the possibility, however, that certain nontuberculous sera having lipotropic properties might fix complement with this antigen. In a large series of experiments in which the Besredka tuberculin was deprived of its lipins by means of extraction with ether in a separatory funnel it was proved that the lipins have no antigenic value in the complement fixation test. The relations of the constituents, such as proteins, etc., of the tuberculin to the antigenic properties are being studied in this connection.

On the value of a new skin test for diagnosis of tuberculosis, J. BRONFENBRENNER (*Abs. in Science, n. ser.*, 39 (1914), No. 1013, pp. 803, 804).—"Subcutaneous injection of 0.55 cc. of a mixture of fresh blood of patients suffering from tuberculosis (1 cc.) with tuberculin (crude diluted 1:10, 0.1 cc.) into a normal guinea pig causes a local reaction, similar in its aspect to a tuberculin reaction, which is of good prognostic value in diagnosis of tuberculosis."

The behavior of tuberculin in the tuberculous and nontuberculous organisms, W. G. RUPPEL and K. JOSEPH (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 21 (1914), No. 1-5, pp. 277-295).—It was found that dead, intact, or rubbed up tubercle bacilli when given intravenously to guinea pigs and to rabbits do not excite the symptoms of an acute intoxication. The chronic symptoms which result after giving normal guinea pigs killed tubercle bacilli may simply be caused by introducing foreign bodies and bringing about anatomical changes.

Aqueous extracts made from disintegrated tubercle bacilli when given subcutaneously to tuberculous guinea pigs produce a fall of temperature and are lethal in amounts of 0.0005 gm. Smaller doses of the soluble poison produce first a rise and then a fall in temperature. In healthy animals the poison extracted by water from tubercle bacilli produces a rise in temperature, and only with large amounts (0.025 gm. of soluble dry substance) is a fall of temperature with subsequent death observed. The lethal dose for healthy animals is 500 times greater than that for tuberculous animals.

The germ-free filtrates from tubercle bacilli bouillon cultures do not contain substances toxic for normal guinea pigs, these originating from the metabolic processes of the bacillus. Pure glycerol was found to kill normal guinea pigs in doses of 4 cc., but its toxicity can be markedly increased by an addition of nontoxic amounts of soluble tubercle bacillary substances. One gm. nucleic acid from tubercle bacilli (tuberculinic acid) contains 400 normal doses for tuberculous guinea pigs, but only 4 lethal doses for healthy guinea pigs, and 0.025 gm. of thymus nucleic acid is lethal for a healthy or tuberculous guinea pig. The specific breadth, that is, the relation of the lethal amounts of poison in 1 gm. of substance for 1 gm. of live weight of a tuberculous subject to the amount of poison necessary to kill 1 gm. of a healthy guinea pig, is for tuberculinic acid 100, whereas for thymus nucleic acid it is —1.

It is believed that the method for testing tuberculin on guinea pigs in use at the present time should be retained. The tubercle bacilli poison can not be regarded as a true bacterial toxin because it does not yield antitoxin nor specific amboceptor in normal animals. In tuberculous animals, however, it produces normal precipitins and specific amboceptors. It seems, therefore, that in the tubercle bacilli there are present two different antigens, one which induces the formation of precipitins and the other specific amboceptors. By treating tubercle bacilli with silicic acid it is possible to separate the precipitinogen from the specific toxin.

Tuberculosis protective vaccination with antiphymatol, T. KRAUTSTRUNK (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 14 (1913), No. 6, pp. 366-382).—The Klimmer method was tested in three establishments. Autopsies were made on 55 animals, 21 of which were protectively vaccinated, 10 curatively treated, and 24 served as controls.

Nine of the protectively vaccinated animals were found tuberculous, 2 animals receiving curative treatment after 3½ years had open tuberculosis, and 1 animal receiving a second injection of antiphymatol had udder tuberculosis. The substance is considered of no value as a protective or curative agent.

The tuberculosis problem in rural communities, S. A. KNOPF (*Pub. Health Rpts. [U. S.], Reprint 243* (1914), pp. 11).—The author believes that because of lack of knowledge and of the enforcement of well-known methods of prevention it is difficult to control the spread of tuberculosis among persons in rural communities. He suggests that there is need of a campaign of education to be followed by a more vigorous control of those afflicted with the disease.

Contribution to the serodiagnosis of infectious abortion in bovines, A. KLOUBOK (*Österr. Wehnschr. Tierheilk.*, 1914, pp. 133, 139; *abs. in Berlin. Tierärztl. Wehnschr.*, 30 (1914), No. 43, p. 721).—This is a study of the agglutination and complement fixation tests as regards their value for diagnosing infectious abortion in bovines. 8 animals from a healthy establishment and 145 animals located in 8 infected barns being used.

Both tests were found valuable for this kind of work, but on account of its simplicity the agglutination test is preferred. A positive test indicates that the animal is infected with *Bacillus abortus*, but not as to whether a specific infection of the uterus has taken place. It also will not determine whether abortion will take place, as pregnant, positive-reacting animals have gone on to full term.

A note on Syngamus laryngeus from cattle in the Philippine Islands, M. C. HALL (*Amer. Jour. Vet. Med.*, 10 (1915), No. 6, pp. 395, 396, figs. 3).—This nematode, previously known from Annam only, is here recorded from the cow and the carabao in the vicinity of Manila. Aside from the irritation at the point of attachment, no pathological condition results from its presence.

Hog cholera and paratyphoid of pigs, H. MIESSNER (*Deut. Tierärztl. Wchnschr.*, 22 (1914), No. 5, pp. 70-73).—A criticism of a circular sent out by a commercial concern to the veterinary profession in regard to vaccination against shoat typhoid. Shoat typhoid is not considered a separate entity, but must be regarded as paratyphoid of pigs caused by the paratyphoid B bacillus. The name shoat typhoid is not deemed well chosen. A chart issued by the concern gives a differential diagnosis between shoat typhoid and hog cholera.

What is hog cholera? F. HUTYRA (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 5, pp. 338-340).—A criticism of the nomenclature suggested for hog cholera, etc., by Schern and Stange (*E. S. R.*, 33, p. 182).

Remarks on the hog cholera question, E. JOEST (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 6, pp. 427-441).—The present conception of hog cholera is said to comprise two etiologically different diseases, viz. one caused by the filterable virus and the other by bacteria of the typhoid coli group (*Bacillus suispestifer*, *B. veldagsen*, *B. typhi suis*, etc.). To this can also be added a third condition caused by the filterable virus and bacteria, viz. mixed infection.

The names shoat typhoid and paratyphoid are not thought to be well chosen, a more appropriate term seeming to be bacillary hog cholera. The name parapest, suggested by Schern and Stange (*E. S. R.*, 33, p. 182), should also receive due consideration. Hog cholera in the unrestricted sense may be classified into two groups: (1) Virus pest and pest (mixed infection), and (2) bacillary hog cholera (parapest). Group 1 comprises hog cholera in the restricted sense. The hog cholera usually met with in Germany is probably a mixed infection.

Much difficulty is experienced when attempting to classify hog cholera on the basis of the patho-anatomical findings. Hog cholera appears clinically and pathologically as a hemorrhagic septicemia, especially when the filterable virus is virulent and has the upper hand. In Germany hog cholera patho-anatomically considered is very severe in nature, and is characterized by inflammation and necrotic changes in the intestinal canal, especially in the large intestine. Septicemic-hemorrhagic manifestations are often absent, especially when the disease is chronic in course, or they are in a minority when compared with the other intestinal changes.

Doubt is expressed as to whether hog cholera, considered in the restricted sense, and parapest (shoat typhoid) can be differentiated on the basis of the patho-anatomical findings. Shoat typhoid usually runs a chronic course, while hog cholera is chiefly an acute condition. According to the author's experience the necrotic processes in chronic hog cholera (restricted sense) seems to lie in the solitary lymph glands of the intestinal mucosa, whereas in the bacillary disease (shoat typhoid) the changes are often diffuse. Button formation is by no means a regular thing in hog cholera. In chronic hog cholera the necrosis plays a part. The wall surrounding the intestinal lesions, said to be characteristic of shoat typhoid, is also found around the typical necrosed areas undergoing a process of healing in hog cholera.

Immunization against erysipelas in hogs especially with killed cultures and bacterial extracts, K. BURBKART (*Abs. in Berlin. Tierärztl. Wchnschr.*, 31 (1915), No. 4, pp. 41, 42).—The purpose of this work was to determine whether immunization could be made with either killed bacteria or bacterial extract. The tests were carried out with gray mice, rabbits, horses, bovines, and a sheep, pig, and goat. Although agglutinin production was noted no satisfactory protective serum could be elaborated.

Filariasis in native horses, D. WIRTH (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 10 (1911), No. 2-3, pp. 161-174, pl. 1; 12 (1912), No. 3, pp. 295-298; 15 (1914), No. 2, pp. 135-138).—The first two papers report upon four cases under observation and a like number are dealt with in the third.

The use of neosalvarsan, J. FÜRI (*Állatorvosi Lapok*, 37 (1914), No. 27, pp. 321-323; *abs. in Berlin. Tierärztl. Wehnschr.*, 30 (1914), No. 47, p. 769).—Neosalvarsan was employed for influenza in horses with good results. The substance can be suspended in glycerin, or, in what is still better, from 10 to 20 cc. of physiological salt solution for injections. This chemotherapeutic agent is also recommended for treating emaciated horses or those affected with acne.

RURAL ENGINEERING.

Irrigation and soil conditions in the Sierra Nevada foothills, California, R. D. ROBERTSON and J. W. NELSON (*California Sta. Bul.* 253 (1915), pp. 325-378, pl. 1, figs. 26).—This report is based on work done under cooperative agreements between the Office of Experiment Stations, the state department of engineering, and the station. Its purpose "is to show the present status and the possibilities of irrigation in the foothills along the western slope of the Sierra Nevada, California, to describe in general the soils of this region, and to discuss the adaptation of these soils to various crops."

The area dealt with is about 5,000,000 acres, the topography consisting of deeply dissected canyons, rugged, rocky ridges, slopes, rounded hills of gentle to moderate contour, and small, narrow, winding valleys. The soils of the region are chiefly of granitic and metamorphic origin. They are relatively high in iron and are prevailing red in color, although areas of gray, brown, and black occur. The prevailing textures are those of loams and clay loams. The soils generally have a friable, mealy texture when damp, are filled without difficulty, and are said to be particularly adapted to the growing of fruit. Their humus content is relatively low, but usually increases with the elevation. "The topography and drainage of the foothills are not favorable in most places for the development of a high-water table or for the accumulation of alkali. . . . The abundance and thrift of native vegetation over the entire belt is a fair indication of the depth, fertility, and moisture-retaining properties of the soil."

Water for irrigation is said to be available for much of the land from numerous streams and reservoirs. The principal rivers furnishing water for irrigation from south to north are as follows: "Above San Joaquin Valley—Kern, Tule, Kaweah, Kings, San Joaquin, Merced, Tuolumne, Stanislaus, Calaveras, Mokelumme, and Cosumnes rivers; above Sacramento Valley—American, Bear, Yuba, Feather, and Sacramento rivers. Throughout the Sierra foothills there are numerous springs which may be made to yield a large revenue if the flow from them is stored in small reservoirs. . . . Only storage works are needed to conserve large volumes now running to waste to make this belt of elevated land one of the most important agricultural districts in California."

It is stated that the principal irrigation developments of the foothill region are found in the Tulare and Fresno counties citrus belt, in the Placer County deciduous fruit belt, and in the vicinity of Oroville in Butte County. Irrigation conditions in these localities are described more or less in detail.

[Irrigation experiments on the Koppenhof experimental field], G. RICHTER (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg*, 1913, pp. 46, 47).—Irrigation on a light sandy soil was accompanied by profitable increases in the yield of potatoes, winter rye, and oats with reference to the cost of irrigation. Complete fertilization of the potatoes without irrigation was accompanied by the same increase in yield as irrigation without complete fertilization. The increase in winter rye was profitable only with heavy irrigations of 240 mm. (9.5 in.). Frequent harrowing of the rye was found a decided advantage.

[Irrigation experiments on the Bromberg experimental field], G. RICHTER (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg*, 1913, pp. 39-43).—Irriga-

tion by spraying amounting to 130 mm. (5.1 in.), extending from April 1 to June 30, plus 120 mm. of rain was accompanied by a decided increase in the crop of winter rye. An irrigation of 180 mm. only slightly increased the yield further. One hundred and ten mm. and 290 mm. of spray irrigation plus 403 mm. of rain water were accompanied by a decided but unprofitable increase in the yield of hay on sandy soil. The root development was also decidedly increased.

The results with beans on a sandy soil using 125 mm. of irrigation were not profitable, but the increase accompanying an irrigation of 165 mm. was quite profitable. Negative results accompanied the irrigation of white and red cabbage on sandy soil and of red beets on heavy soil. Tomatoes on sandy soil burst and rotted badly on account of an abnormal rainy period, especially on the irrigated plats. In spite of this the profit due to increase of crop accompanying irrigation was marked. An excellent profit was obtained by the irrigation of fruit bushes and trees on sandy soil using 70 mm. and 150 mm. of irrigation plus 120 mm. of rain. Profitable results accompanying irrigation were obtained with sugar beets on a heavy soil in only two out of four cases, but irrigation was quite profitable with carrots on this soil with 40 mm. and 50 mm. of irrigation plus 400 mm. of rainfall from May 1 to September 30. An irrigation of 110 mm. slightly increased this profit.

The water economy of the soil, G. RICHTER (*Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg, 1913, pp. 43-45*).—In studies of the influence of cultivation on the water economy of light sandy soil it was found that harrowing five times immediately after rains was accompanied by a marked increase in the yield of corn. Irrigation increased the water content of both the surface soil and subsoil of grass land, but the water content of the subsoil decreased with the depth and with the amount of living and dead root matter. The water content of meadow and barley soils even when unirrigated was greater than that of grass and rye land, indicating, it is thought, that rye and grass possess a greater ability to utilize the water. Plowing and harrowing of the rye soil after harvesting followed by fallowing increased the water content of the surface soil about 2.1 per cent by weight, but did not affect that of the subsoil.

Studies in water supply, A. C. HOUSTON (*London: Macmillan & Co., Ltd., 1913, pp. XII+203, pl. 1, figs. 42*).—The contents of this monograph have been previously noted (*E. S. R., 31, p. 416*).

River discharge, J. C. HOYT and N. C. GROVER (*New York: John Wiley & Sons, 1914, 3. ed. rev. and enl., pp. XII+182, pls. 10, figs. 38*).—This is the third edition of this book (*E. S. R., 29, p. 487*), and has been further expanded to present the latest information on the subject.

Surface water supply of the Yukon-Tanana region, Alaska, 1907 to 1912, C. E. ELLSWORTH and R. W. DAVENPORT (*U. S. Geol. Survey, Water-Supply Paper 342 (1915), pp. 343, pls. 13, figs. 5*).—This report gives a detailed summary of the water-supply studies in the Yukon-Tanana region since 1907, these having been discontinued indefinitely. The work of 1907 and 1908 has been previously noted (*E. S. R., 21, p. 309*).

The physical and climatic features of the region are first described, followed by descriptions of stream basins and the results of measurements of flow therein. It is stated, among other things, in conclusion that the stream flow in the region is generally unfavorable for hydraulic development. "The conditions of the Yukon-Tanana region are particularly unfavorable for the development of water power. The combinations of low minimum run-off without natural storage or favorable means of developing artificial storage, of low and uniform stream grades, of short seasons, and of variable market make the use of water power a last resort."

Report on the surface water supply of New Mexico, 1913, J. A. FRENCH (*Santa Fe, N. Mex.: State Engin. Dept., 1913, pp. 216, pls. 5*).—This report covers floods in the Chico Rico Creek basin in June, 1913; Cimarron River basin in June, 1913; Mora River and Sapello Creek drainage basins in 1913; and Rio de Arena and Cameron Creek drainage basins in August, 1913. It also gives miscellaneous measurements in the Canadian and Gila River basins, seepage investigations of the Rio Grande, and evaporation data.

The inverted weir, E. W. RETTGER (*Engin. News, 73 (1915), No. 2, pp. 72, 73, figs. 4*).—The author in dealing with special properties of certain weir forms when used inverted calls attention especially to the proportional-flow inverted weir. See also a previous note (E. S. R., 31, p. 784).

Report upon the Cypress Creek drainage district, Desha and Chicot counties, Arkansas, S. H. McCROBY, O. G. BAXTER, D. L. YARNELL, L. A. JONES, and W. J. SCHLICK (*U. S. Dept. Agr. Bul. 198 (1915), pp. 20, pls. 4, figs. 2*).—This drainage project, the survey for which was completed in March, 1912, embraces a district in southeastern Arkansas having an area of 466 square miles and classed as Mississippi bottom land. The topsoil generally is the ordinary Mississippi alluvium, more or less modified by decayed vegetation.

"The water from which the district must be protected comes from two sources—first, direct precipitation upon the watershed in which the district lies, and, second, overflow from the Mississippi River, whose backwater enters the district through the gap in the levees at the mouth of Cypress Creek, damaging not only the district itself but a large area in Chicot County, Ark., and northern Louisiana, since such water, once behind the Mississippi River levee, must flow south to the Red River. The drainage problem, then, is not only to provide the necessary outlets and laterals to care for the run-off from the 658 square miles tributary to that district but so to design and locate these outlets that the drainage water now entering the Mississippi River through the levee gap will be diverted, thus making it possible to close this gap."

From run-off observations made in this and similar districts, the following formula of the Fanning type was deduced for use in calculating run-off in this project: $R = \frac{35}{\sqrt{M}}$. R =the run-off in second-feet per square mile and M =the area of watershed in square miles.

The proposed improvement includes 421.72 miles of ditches, the total cost of construction of which is estimated at \$2,207,493, or \$7.49 per benefited acre.

Excavating plant for heavy drainage work in Arkansas (*Engin. Rec., 71 (1915), No. 2, p. 41, fig. 1*).—This article deals with the type and dimensions of machinery adapted to channel and levee construction in timbered alluvium. The floating dipper dredge is preferred for this work.

The economy of farm drainage, R. D. MARSDEN (*U. S. Dept. Agr. Yearbook 1914, pp. 245-256, pls. 4*).—In this article a brief discussion of the beneficial effects of land drainage and of surface and subsurface drains and their adaptations is followed by a more detailed discussion of the economic phases of the subject.

The cost of drainage is shown to be a factor varying not only with location, owing to differences in the cost of tile and labor, but with the nature of the soil and with the consequent depth and spacing of drains. It is stated that in considering the economy of farm drainage it is proper first to compare the anticipated results with the probable returns from otherwise investing the money that the drainage work will cost.

Proper planning of drainage projects is considered essential. "To determine the most economical plan of drainage usually requires engineering judgment of no mean order and a thorough knowledge of the drainage properties of soils.

One not experienced in this kind of work should not take the responsibility of planning any considerable expenditure for drainage. . . . Construction work should be carefully done, under the supervision of some one at least qualified to see that the tile are laid according to the grades established by the engineer who planned the work. . . . The fertility of the soil should be assured before drainage is planned and if any element of plant food is lacking the cost of supplying it must be reckoned."

Clean water and how to get it on the farm, R. W. TRULLINGER (*U. S. Dept. Agr. Yearbook 1914*, pp. 139-156, pls. 3, figs. 4).—This article discusses the sanitary aspects of farm water supplies, illustrates good and bad well and spring surroundings, gives information regarding the protection of farm water supplies from contamination, and describes convenient methods for obtaining running water in the house. A report by the author dealing in part with the same subject has been previously noted (*E. S. R.*, 30, p. 690).

Annual report on highway improvement, Ontario, 1913, W. A. McLEAN (*Ann. Rpt. Highway Imp. Ont., 1913*, pp. 62, figs. 24).—This report deals with model and experimental roads, road models, road machinery, specifications for road machinery, concrete roads, and pavements in Ontario, and township road administration.

As regards grading machines, it is stated that they are of greatest value in purely agricultural districts, working constantly in uniform clay, loam, and sandy soils. Steam rollers are considered a necessity wherever broken-stone roads are being built, 10-ton rollers being the best for ordinary country use. It is stated that traction haulage, displacing horses, for hauls of 2 miles or over shows distinct economy, in some cases reducing by one-half the cost of hauling gravel and stone. The objections presented to concrete as a material for roads are that the surface is too hard to give a proper foothold for horses, it is rigid and hard on their feet, it reflects heat, it has an unpleasant glare, it is brittle, expansion joints chip at the angles and under constant traffic deepen to holes, and cracks are unavoidable and difficult to repair. On the other hand, concrete for pavements is said to be low in first cost as compared with other high-class pavements, and is one of the cheapest materials yet available for a permanent pavement or roadway.

The present concrete road practice in Ontario is said to favor one-course construction, rich in cement, coupled with careful drainage of the subsoil.

Traffic factors, J. EASTWOOD (*Surveyor*, 46 (1914), No. 1185, pp. 408-412).—The author deals with the conditions influencing the value of coefficients of potential damaging effect under English conditions and reports a traffic census on two roads, from the results of which he proposes factors for certain classes of traffic for both macadam and paved roads as shown in the following table:

Proposed traffic factors.

Kind of traffic.	Macadamized roads.		York stone paving.		Granite.	
	Level.	Steep.	Level.	Steep.	Level.	Steep.
Led or ridden horses	1	2	$\frac{3}{2}$	1	$\frac{1}{2}$	$\frac{1}{2}$
Single-horse vehicles (light)	2	4	1	$1\frac{3}{4}$	$\frac{1}{2}$	$\frac{1}{2}$
Single-horse vehicles (heavy)	4	6	2	3	$\frac{1}{2}$	$1\frac{1}{2}$
Two-horse vehicles (light)	4	6	2	3	$\frac{1}{2}$	$1\frac{1}{2}$
Two-horse vehicles (heavy)	6	9	3	$4\frac{1}{2}$	1	$1\frac{1}{2}$
Three-horse vehicles	7	12	$3\frac{1}{2}$	$5\frac{1}{2}$	$1\frac{1}{2}$	$2\frac{1}{2}$
Four-or-more-horse vehicles	9	15	$4\frac{1}{2}$	$6\frac{1}{2}$	2	3
Motor cycles	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	$1\frac{1}{2}$	0	0
Motor cars	8	8	$1\frac{1}{2}$	$1\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$
Motor wagons (rubber tires)	12	12	2	2	1	1
Motor wagons (steel tires)	20	20	20	20	20	20

Relation of road maintenance to traffic, W. D. SOHIER (*Engin. Rec.*, 70 (1914), No. 22, pp. 582-584).—Studies of traffic and repair on Massachusetts highways with reference to the influence of volume, weight of units, relative number of rubber and steel tired vehicles, and cost of maintenance are reported.

The largest cost of upkeep on macadam roads in Massachusetts is said to be due to heavy automobile travel and heavy hauling on narrow tires. Traffic values of gravel and water-bound macadam roads are given in the following table:

Traffic values of gravel and water-bound macadam roads.

Conditions of traffic.	Average daily traffic.			
	Light teams, carriages, wagons.	Heavy teams, one-horse.	Heavy teams, two or more horses.	Automobiles.
A good gravel road will wear reasonably well and be economical with.	50-75	25-30	10-15	50-75.
It needs to be oiled with.....	50-75	25-30	10-15	Over 75.
Oiled gravel, fairly good heavy cold oil $\frac{1}{2}$ gal. per square yard, applied annually, satisfactory with.	75-100	30-50	20	500-700 or more.
Water-bound macadam will stand with.....	175-200	175-200	60-80	Not over 50 at high speed.
Cold oil or tar will prove serviceable on such macadam with.	175-200	175-200	60-80	50-500.
Macadam will then stand, but the stone wears, of course, with.	175-200	175-200	60-80	500 or more.
Water-bound macadam with hot asphaltic oil blanket will be economical with.	100-150	50-75	25-30	1,500 and more with fewer teams.
Do., will stand at least.....	150	75	30	50 trucks.
Do., will crumble and perhaps fail with more than (on narrow tires, ice, farm, and wood teams, etc.).	150	75	30	
Water-bound macadam with a good surface coating of tar ($\frac{1}{2}$ gal. per square yard recoated annually with $\frac{1}{4}$ gal. of tar per square yard) will stand with.	100-150	50-75	25-30	1,500 or more.

Notes on the selection of pavements for heavy-traffic roads, H. G. SHIRLEY (*Engin. and Contract.*, 42 (1914), No. 24, pp. 537, 538).—An outline of the factors involved in the selection of pavements for use on country roads subjected to heavy traffic, including excessive loads hauled by tractors, is given.

It is stated that before selecting the type of pavement to be used a more or less accurate census of the different kinds of traffic should be taken and an estimate made as to the possible increase or decrease of the different kinds. The following criterion for the selection of the type of pavement is suggested: "Where the annual cost of maintenance of a less durable type of road surfacing will exceed the annual cost of maintenance of a more durable type of surfacing, plus 4 per cent on the excess cost of the more durable type over the less durable type, the more durable type should be used, and vice versa."

State management of public roads, its development and trend, J. E. PENNY-BACKER (*U. S. Dept. Agr. Yearbook 1914*, pp. 211-226, pls. 2, figs. 3).—In this article, dealing mainly with economic phases of the subject, it is stated, with reference to the progress of state road management, that forty-two States have thus far established highway departments for educational or administrative work, and of these thirty have made actual appropriations in aid of road construction or maintenance. "In all, \$208,000,000 had been appropriated from state funds between 1891 and January 1, 1915, for construction, maintenance, administration, and educational road work, and a total of about 31,000 miles of improved roads is the evidence to show that this expenditure was not in

vain. These roads were built for the most part as a joint state and local undertaking, so that a large local outlay not included in the state total was involved. . . .

"The systems of road management now prevailing in the various States may be grouped in six general classes. The first class comprises those States in which the construction of all roads is more or less under state control. In the second class are comprised those States in which state control of road construction is limited to those roads on which state funds are expended. In the third class are included the States which grant aid in the form of state funds, but allow the expenditure to be made under local control. In the fourth class are those States which have established highway departments for educational and advisory work. The fifth class is composed of the States which devote the labor of state convicts to road improvement, and the sixth class comprises those States in which the control of all road construction is entirely local. . . .

"Summarized briefly, the essentials to successful state highway administration, as demonstrated by the experience of the various state highway departments, are as follows: (1) The elimination of politics as a factor in state highway work, (2) the control by the state highway department of all work on which state funds are expended, (3) adequate appropriations for continuous maintenance of highways under efficient supervision from the day the highways are completed, and (4) state supervision as to surveys, plans and specifications of roads and bridges constructed under bond issue, and supervision of such other road and bridge work as requires considerable cash outlay and the exercise of engineering skill and knowledge."

Standard concrete culverts recommended by the Michigan Highway Department (*Engin. and Contract., 43 (1915), No. 2, p. 44, fig. 1*).—Tables and diagrams showing the standard type of concrete culvert for spans varying from 6 ft. to 18 ft., as recommended by the Michigan State Highway Department, are given.

Making fences, walls, and hedges, W. H. BUTTERFIELD (*New York: McBride, Nast, & Co., 1914, pp. 66, pls. 8, figs. 17*).—This book deals with the construction of fences, gates, and walls. The text is divided into sections dealing with fences and their construction, walls (stone), and hedges.

Mechanical cultivation in Belgium, P. DIFLOTH (*Vie Agr. et Rurale, 3 (1914), No. 26, pp. 716-721, figs. 5*).—The actual experimental data of motor-plow tests previously noted by De Chassart et al. (*E. S. R., 31, p. 487*) are reported in complete form. The more important results are given in the following table:

Results of mechanical plowing tests.

Kind of machine.	Rated horsepower.	Number of plows.	Average plowing width.	Plowing depth.	Total surface plowed in test.	Volume soil turned per hour.	Fuel consumption in test.		Lubricating oil consumed in test.
							Essence.	Coal.	
Steam:			<i>Meters.</i>	<i>Cm.</i>	<i>Hectares.</i>	<i>Cu. met.</i>	<i>Liters.</i>	<i>Kg.</i>	<i>Liters.</i>

Scarifier.....	30	2.00	15.5	3.4116	345.5	132.00	4.18

Results of some experiments made to determine the effect of varying the percentage of water in concrete (*Engin. and Contract.*, 42 (1914), No. 11, pp. 244-246, figs. 4).—The results of a series of experiments, using 6-in. cubes and reinforced beams 2 in. by 2 in. by 3 ft. of a 1:2:4 mixture and a water content varying from 20 to 42.5 per cent of the weight of the cement, are reported. The cubes were broken at the end of 7, 30, and 60 days and the beams at the end of 30 and 60 days. The beams were reinforced with two $\frac{3}{8}$ -in. round rods and designed to carry a load of 274 lbs. placed at the center of the span.

In breaking the cubes the 27.5 per cent of water mixture appeared to be the most desirable as regards strength. A drier mixture than this was noticeably weaker and a slight increase in the amount of water resulted in a decided decrease in strength. In breaking the beams the 27.5 per cent of water mixture also proved the strongest, both at the end of 30 and 60 days. The relative strength of the concrete beams varied as regards the water percentage, and was practically the same as in the cubes of the same consistency.

Tensile tests of mortar briquettes containing 20 oz. of sand and 12 oz. of cement showed that the mixture which gave the maximum strength was a trifle drier, containing 25 per cent of water against 27.5 per cent for the beam and cube tests, but the general relation of consistency to strength was the same.

RURAL ECONOMICS.

The organization of a rural community. T. N. CARVER (*U. S. Dept. Agr. Yearbook 1914*, pp. 89-138, figs. 2).—The author presents a plan for the organization of a rural community, intended as a general guide for those interested. He classifies the needs of rural communities which require organization as business needs and social needs. Under each of these he has selected five major needs, for each of which he suggests the appointment of a special committee.

The committees on business interests are those on farm production, marketing, securing farm supplies, farm finance and accounts, and communication and transportation. Those on social interests are on education, sanitation, recreation, beautification, and household economies. There is also a central committee consisting of the officers of organization and the chairmen of the various committees.

Concerning the organization of agricultural enterprises (*Bol. Agr. Téc. y Econ.*, 6 (1914), Nos. 67, pp. 610-620; 68, 702-712; 69, 818-827; 70, 915-924; 71, 1001-1011; 72, 1097-1107).—These articles relate to the type of agriculture found in Spain, and suggest reforms to make it more efficient.

Information on rural economy and administrative organization of agriculture (*Brussels: M. Weissenbruch, 1913*, pp. 48, pls. 5).—This report contains a brief description of the various activities of the department of agriculture in Belgium. It relates principally to methods used in improving the live stock, controlling animal diseases, and carrying on educational work in agriculture and home economics and experimental work.

[Winter agricultural work]. A. HOFMEISTER (*Mitt. Deut. Landw. Gesell.*, 29 (1914), Nos. 47, pp. 637-639; 48, pp. 648-650; 49, pp. 661, 662; 51, pp. 688-691).—This article indicates methods that may be used to keep the men and women on farms fully employed at profitable work during the winter season.

The cost of production on Missouri farms, O. R. JOHNSON and W. E. FOARD (*Missouri Sta. Bul. 125 (1915)*, pp. 287-316, figs. 5).—The authors outline their method of investigation and indicate the cost per acre of the principal crops

on the farms studied and the cost of keeping the different farm animals. A portion of the work was in cooperation with the Office of Farm Management of this Department.

It was found that the cost of using equipment varied from 1.3 cts. per horse-hour on one farm to 3.8 cts. per horse-hour on another, the average for 12 farms being 2.28 cts. The average cost per year of keeping a work horse on 14 farms was \$88.33, of which 77.4 per cent was spent for feed, 10.7 for labor, and 11.9 for miscellaneous. The average length of workday per horse on 28 farms was 3.57 hours, and the average cost per hour of horse labor on all farms 7.9 cts. The average length of workday per man on 28 farms was 9.64 hours, and the average cost per hour on 6 farms 13 cts. The following table indicates the cost and the amount of man and horse labor required to produce the crops mentioned:

Acre cost of producing various farm crops.

Crop.	Man labor.	Horse labor.	Cost.
	<i>Hours.</i>	<i>Hours.</i>	
Corn.....	23.92	42.32	\$13.52
Oats.....	10.83	19.48	10.87
Wheat.....	11.78	21.37	12.30
Soy beans.....	24.73	36.31	13.53
Cowpeas.....	24.25	40.05	13.60

The authors found that when the yields of corn were less than 30 bu. per acre, the corn paid practically nothing for the man labor. They also found that the average annual cost of keeping a cow for supplying home needs was \$47.95 on 6 farms, while on a single dairy farm of 12 cows it was \$85.10. The latter returned a net loss of \$4.18. They found that the cost of keeping a brood sow was \$25.91; the cost of keeping a hen a year under farm conditions was 65.7 cts.

Market distribution (*Amer. Econ. Rev.*, 5 (1915), No. 1, Sup., pp. 112-161).—The papers and discussions included under this topic relate primarily to the marketing of agricultural products.

R. Meeker maintains that the only way to bring the producer and consumer effectively and permanently together is through the organization of the market. The first step should be to organize the farmers into local cooperative associations. The object of these associations should be, (1) to determine upon the crop or crops to be grown for shipment to market; (2) to insist upon proper methods of growing the crops; (3) to standardize and guarantee the quality of the products shipped; (4) to superintend the gathering, grading, and packing of crops; (5) to arrange for proper and sufficient means of transportation, handling, shipping, and terminal facilities; and (6), to bargain with railroads and other transportation companies for a freight rate that will be a livable rate for both the farmer and the transporter.

L. D. H. Weld calls attention to the fact that the principal reasons for variation in the cost of marketing agricultural products are the degree of perishability, regularity and irregularity of supply throughout the year, waste and shrinkage, volume in which the products are handled, extent into which a commodity may be subdivided, existence of well established qualities or grades, and the relation between bulk and intrinsic value.

The remaining papers relate principally to a discussion of the points brought out in these two addresses.

Retail public markets, G. V. BRANCH (*U. S. Dept. Agr. Yearbook 1914*, pp. 167-184, pls. 4).—The author discusses the local needs and demands for markets, types, location, construction, financing, market regulations and management, and news service of public markets, as factors which should be considered in the establishment of such markets. He concludes that "while the municipal retail market surely has its place in the present system of food distribution, its introduction should be accompanied with even more mature judgment than would attend the establishment of business institutions by private agencies, for, in committing itself to the retail-market policy, a city is departing somewhat from the conservative path. The public market is not a panacea for the weaknesses of the retail system, nor is it advocated that its use should displace the old established agencies of retail marketing. Rather, its service should supplement, cooperate with, and to some extent regulate that which they give."

Farmers' market bulletin (*North Carolina Sta. Farmers' Market Bul.*, 2 (1914), No. 2, pp. 31).—This bulletin outlines methods for marketing eggs through creameries and for organizing to grade and market corn, and discusses the work of the state division of markets. It includes the text of the act of 1915 to provide for the incorporation and maintenance of cooperative organizations, and the usual list of products for sale.

Cooperative marketing, and financing of marketing associations, C. E. BASSETT, C. W. MOOMAW, and W. H. KERR (*U. S. Dept. Agr. Yearbook 1914*, pp. 185-210, pl. 1).—This article points out the advantages of the cooperative marketing of farm products, discusses the basic principles and conditions favoring success, and describes some forms of organization and different methods of financing cooperative enterprises.

Departmental committee on agricultural credit in Ireland (*Dept. Agr. and Tech. Instr. Ireland, Dept. Com. Agr. Credit Ireland, Minutes of Evidence, etc.*, 1912-13, pp. XIV+671).—This volume contains the minutes of the evidence gathered in connection with the report previously noted (*E. S. R.*, 32, p. 286).

[Transportation of agricultural products in France] (*Bul. Mens. Off. Recenseig. Agr. [Paris]*, 13 (1914), Nos. 2, pp. 194-212; 3, pp. 300-329; 4, pp. 394-406; 6, pp. 725-732).—These articles note the various means used in distributing agricultural products in France, giving the tariff rates, quantities moved, time in transit, and movement between distributing centers.

Movement from city and town to farms, G. K. HOLMES (*U. S. Dept. Agr. Yearbook 1914*, pp. 257-274).—The author points out, as the result of a questionnaire sent to about 45,000 crop correspondents, that there are five main classes of people appearing in the movement from city and town to farms: (1) Those who move to the country for the purpose of owning a farm on which to live throughout the year and of devoting their entire time to agriculture, (2) those who reside on the farm for the entire year but continue their former occupation in a nearby city or town, (3) seasonal residents, (4) those who move to the country to become farm tenants, and (5) those who seek temporary employment as farm laborers. The author considers that the movement consists primarily of the first class, and points out that it is highly varied and covers a wide range of quality, quantity, and efficiency in the contributions. It is a phenomenon of the denser populations and is most evident in the North, east of the Mississippi River, and is quite generally an accompaniment, if not a consequent, of nearly urban conditions.

The American farm woman as she sees herself, E. B. MITCHELL (*U. S. Dept. Agr. Yearbook 1914*, pp. 311-318).—This article is a brief review of the replies received to the Secretary's letter regarding the needs of the farm woman, previously noted (*E. S. R.*, 32, p. 890). The author summarizes these

replies as follows: The farm women "believe that the Government can help them in their struggle in two ways—by economic legislation that will make agriculture more profitable, and by advice and education that will enable them to make the best of what they have."

Conference on rural life and work (*Agr. Gaz. Canada*, 2 (1915), No. 2, pp. 177-180).—These pages contain a summary of addresses and resolutions adopted at a conference on rural life at the Ontario Agricultural College in January, 1915.

The organization of the agricultural statistical service in various countries (*Inst. Internat. Agr. [Rome], Organ. Serv. Statist. Agr.*, 2 (1913), pp. 144).—This report describes the methods of gathering statistics relating to agriculture in Australia, Bulgaria, Spain, Nicaragua, Peru, Servia, Sweden, Tunis, and Uruguay.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt.*, 1 (1915), No. 1, pp. 8).—This report succeeds the Agricultural Outlook, which has been discontinued, and is a resumption of the Crop Reporter, which was discontinued June 19, 1913. This report contains estimates of the condition on May 1 of winter wheat, rye, bees, hay, spring pasture, plowing, planting, apples in storage, acreage and condition of certain truck crops, stocks of wool January 1, etc., estimated farm values of some of the principal agricultural products on this date and of others for April 15, range of prices at important markets, and a yearly summary of the "world" production. Comparative data are given for earlier years.

It is estimated that the total production of straw in the United States is 117,754,000 tons, valued at \$436,867,000, of which 54.9 per cent is fed, 15 burned, 7.8 sold, 10 plowed under, and 12.3 used for other purposes. The value of the straw burned is estimated as equivalent to \$65,000,000.

Annual international report on agricultural statistics for 1911-12 (*Inst. Internat. Agr. [Rome], Ann. Internat. Statist. Agr. 1911-12*, pp. XXXIV+622).—This report shows for both those countries adhering and nonadhering to the International Institute of Agriculture, the total area and population, the productive, nonproductive, and arable area, the area and production of the principal agricultural crops, the number of live stock, international commerce, and prices for agricultural products. The estimated consumption for rye, barley, oats, maize, and wheat is included. Comparative data for earlier years are shown. An extensive bibliography is included indicating the sources used.

[Agricultural statistics] (*Statis. Abs. Brit. Self-Gov. Dominions [etc.]*, 51 (1899-1913), pp. 318-381).—These pages bring up to date the statistical data previously noted (*E. S. R.*, 30, p. 493) relating to the several British self-governing dominions, crown colonies, possessions, and protectorates.

[Agriculture in Argentina] (*An. Dir. Gen. Estad. [Buenos Aires]*, 2 (1912), pp. 10-57).—These pages of the annual report contain information concerning the area and production of the principal crops, number of live stock, and trade and manufactures of agricultural products.

Agricultural statistics of British India (*Statis. Abs. Brit. India*, 48 (1903-4-1912-13), pp. 126-135).—These pages of the annual report contain statistical data showing the area devoted to different agricultural purposes, area and production of specified crops, number and amount of land transferred, and area in forests. The statistics for 1913 are shown by provinces. Comparative data for 1903-4 to 1912-13 are shown for the country as a whole (see also a previous note (*E. S. R.*, 30, p. 392)).

[Agricultural population of British India] (*Statis. Abs. Brit. India*, 48 (1903-4-1912-13), pp. 15-17).—The census of 1911 indicated that out of a total population of 313,470,014 people, 226,550,483 were dependent upon and engaged

in agriculture. There were 72,577,476 males and 34,199,230 females actively engaged in the agricultural operations of the country.

Live stock in Germany (*Viertelj. Statis. Deut. Reichs. No. 1 (1914). Ergänzungs.*, pp. 135).—This report shows the number and value of the various kinds of live stock on December 2, 1912, by minor subdivisions and of different ages. Comparative data are given for earlier years for the more important items. The following table shows the number at different censuses:

Number of live stock in Germany.

Kind.	1873	1883	1892	1900	1907	1912
Horses.....	3,352,231	3,522,545	3,836,273	4,195,361	4,345,047	4,523,059
Mules.....	1,626	1,009	383	649	942	1,883
Asses.....	11,689	8,786	6,320	7,199	10,349	11,264
Cattle.....	15,776,702	15,786,764	17,555,834	18,939,092	20,630,544	20,182,021
Sheep.....	24,999,406	19,189,715	13,589,662	9,692,501	7,703,710	5,803,445
Swine.....	7,124,088	9,206,195	12,174,442	16,807,014	22,146,532	21,923,707
Goats.....	2,320,002	2,640,994	3,091,508	3,266,997	3,533,970	3,410,396
Hives of bees.....	2,333,484	1,911,797	2,034,485	2,605,350	2,594,690	2,630,837
Poultry.....	No data.	No data.	No data.	64,453,171	77,103,045	82,702,030

AGRICULTURAL EDUCATION.

[**Agricultural**] instruction (*Jahresber. Landw. Königr. Sachsen, 1913, pp. 79-103*).—Brief reports are given for 1913 of institutions in the Kingdom of Saxony giving instruction in agriculture and home economics, and of special courses in these subjects, together with tables showing the attendance by districts for 1913-14 in these agricultural and home economics schools, and the total attendance from 1875 to 1913-14 for the former.

[**Agricultural education under the direction of the chamber of agriculture**] (*Jahresber. Landw. Kammer Rheinprov., 1913, pp. 69-99*).—This is the annual report of progress in agricultural education under the direction of the chamber of agriculture of the Rhine Province, including the work of the Bacteriological Institute, the Educational and Experimental Dairy Institute at Cleve, the Poultry Breeding Station and School at Neuss, agricultural winter schools, special courses, instruction in the army, and itinerant instruction.

[**School gardening and nature study**] (*Nature-Study Rev., 11 (1915), No. 2, pp. 37-79, figs. 17*).—This number comprises the following articles: Children's Home Gardens, by Alice J. Patterson; Vegetable Gardening for City Children, by Ethel Gowans; School and Home Gardening in Portland, Oreg., Season of 1914, by M. O. Evans, Jr.; Beautifying Work as Nature-Study, by Margaret Dolan; Heuristic Method, by L. C. McLean; Nature-Study in the Gary Schools, Margaret Ahearne; The School Fair an Aid to Gardening, by L. A. De Wolfe; Plants for Class-Rooms, by Ellen E. Shaw; and Gardening at Bloomington, Ill., by J. K. Stableton.

The growth and influence of the nature-study idea, ANNA B. COMSTOCK (*Nature-Study Rev., 11 (1915), No. 1, pp. 5-11*).—The author reviews the progress of the nature-study idea and points out its influence and practical benefits.

Boys' and girls' contest clubs, L. H. BAILEY (In *York State Rural Problems, II. Albany, N. Y.: J. B. Lyon Co., 1915, pp. 71-79; Cornell Countryman, 12 (1915), No. 4, pp. 300-303, figs. 2*).—The author discusses four dangers in boys' and girls' agricultural contest work as some of it is undertaken at the present time, viz. (1) that these clubs or contests may not represent real effort on the part of the child, (2) the rewards may be out of proportion to the effort expended, (3) the effect of the contests may be to inflate the child and to give

him an undue estimate of his own importance, and (4) the children are liable to be exploited, used in the making of political or other public reputation, or in accomplishing advertising and propaganda for institutions, organizations, publications, commercial concerns, and other enterprises, or to exploit the resources of the State or the agriculture of a region.

As safeguards against such dangers the author suggests the recognition of the essential nature and function of such contests. "The fundamental consideration is that all this kind of work is educational. It is not primarily agricultural work, not undertaken directly to improve the farming of a region. The primary consideration is its effect on the child." He thinks that this work should be a part of the public school system with laboratory work at home under the direction of the teachers.

Elementary agriculture, A. W. NOLAN (*Nature-Study Rev.*, 11 (1915), No. 1, pp. 27-29, fig. 1).—The author suggests some points to emphasize in teaching boys and girls in an elementary course in agriculture to work out practical and profitable ways of improving farm animals.

Outlines in agriculture, domestic science, and manual training for twelve weeks of normal training (*Des Moines, Iowa: State Dept. Pub. Instr.*, 1915, pp. 14).—Work is outlined under the following topics: Farm crops, soils; horses, cattle, swine, sheep, poultry; and food, clothing, house sanitation, personal hygiene, and manual training. The examinations for state and uniform county certificates in Iowa have been based upon these outlines since July 1, 1915.

Laboratory exercises in principles of agriculture, E. HOPT and R. R. SPAFORD (*Chicago: W. M. Welch Manufacturing Co.*, 1914, pp. 192, figs. 97).—Laboratory exercises in soils, plants, farm animals, and general farm problems, including seasonal fluctuation in the price of farm products, the cost of living, and an illustration of farm plans and crop rotation, are outlined to cover at least 36 weeks. It is suggested that three single periods a week devoted to classroom work and two double periods a week to laboratory work will probably fit most schools. A list of laboratory supplies for the complete course based upon the needs of a laboratory section of 12 students is appended.

Hotbeds: Their construction and use, S. A. MINEAR (*Rural Educator*, 5 (1915), No. 2, pp. 37-39, figs. 5).—The author points out the uses and location of school hotbeds, gives directions for the construction and management of temporary school hotbeds and for growing cabbage under glass, and suggests other vegetables and flowers that may be similarly grown.

Peppers, OLA POWELL, MARY E. CRESWELL, and W. W. TRACY (*U. S. Dept. Agr., Bur. Plant Indus. Doc. 782* (1915), pp. 8).—Instructions are given to the canning-club girls of the South on the cultivation, growing, canning, and some ways of using fresh and canned Spanish peppers.

Identification of potato varieties, C. L. FITCH (*Off. Pub. Iowa State Col. Agr.*, 12 (1914), No. 33, pp. 32, figs. 25).—This subject is considered under the headings of varieties of interest to Iowa growers, the influence of conditions on shape and color, and varieties described and identified by the tuber form and color markings.

Studies of trees, J. J. LEVISON (*New York: John Wiley & Sons*, 1914, pp. X+253, pl. 1, figs. 155).—This book for the beginner, "which gives in a brief and not too technical way the most important facts concerning the identification, structure, and uses of our more common trees, and which considers their habits, enemies, and care both when growing alone and when growing in groups or forests," has been previously noted as a loose-leaf manual (*E. S. R.*, 31, p. 494), with the exception of the chapters on the identification, properties, and uses of our common woods, and an out-door lesson on trees.

Farm forestry. A. AKERMAN (*Athens, Ga.: Jackson, Ga., Progress Print, 1914, pp. 2+54+4, pls. 9*).—This text has been prepared for use in agricultural high schools and colleges in Georgia and surrounding States. It discusses the life processes of trees, the distinguishing characteristics and utility of some of the more important trees of the South, reproduction, protection, thinning, cutting mature timber, preservatives, firewood, and the place of woodlands in farm management. A preliminary outline of this text has been previously noted (E. S. R., 21, p. 339; 22, p. 197).

A manual of exercises in forest mensuration, H. WINKENWERDER and E. T. CLARK (*Seattle, Wash.: Authors, 1915, pp. 146*).—This book gives detailed directions for conducting the various operations involved in the determination of the contents of logs, trees, and stands.

Modern methods of testing milk and milk products, L. L. VAN SLYKE (*New York: Orange Judd Co., 1913, 2. rev. ed., pp. XII+286, pl. 1, figs. 62*).—In this revision of this text (E. S. R., 18, p. 7), chapters have been added on methods of testing butter and cheese for fat, butter for water and for salt, and milk for casein, and several other chapters have been completely rewritten to cover new developments.

The nature-study course of the elementary school, O. W. CALDWELL (*Nature-Study Rev., 10 (1914), No. 9, pp. 358-367, figs. 3*).—A synopsis is presented of the purposes, projects, and materials of the nature-study course for the first to the eighth grades, inclusive. This outline is the result of several years of experience.

The nature-study course of the school of observation and practice, ADELIN F. SCHIVELY (*Nature-Study Rev., 10 (1914), No. 9, pp. 337-358, figs. 6*).—This is an outline of a course planned for grades 2 to 8, inclusive. The subject matter is arranged in seasonal sequence under plant life, animal life, minerals, experimental work (mainly in chemistry and physics), earth study, and miscellaneous. The work is correlated with geography and occasionally with physiology, and garden work, mostly at home, is encouraged.

Nature study, J. A. CHURCHILL (*Nature-Study Rev., 10 (1914), No. 9, pp. 368-374*).—The author outlines a grade plan of nature study for the elementary schools in Oregon and discusses methods of instruction.

Nature study and agriculture (In *A Manual Containing the Course of Study for the Elementary Schools of West Virginia. Charleston, W. Va.: Dept. Free Schools, 1914, rev. ed., pp. 141-169*).—An outline of a course in nature study for grades 1 to 6, inclusive, and in agriculture for grades 7 and 8 is presented, with directions for making an agricultural booklet. The use of notebooks and the bulletin board, collections, correlation, preliminary school exercises, contests, and home and community projects are recommended.

Nature study at the Van Vliissingen School, G. A. BRENNAN (*Nature-Study Rev., 11 (1915), No. 1, pp. 12-25, figs. 4*).—An outline is given of the course in nature study from the kindergarten to the eighth grade, inclusive, used in the Van Vliissingen School, located in Roseland, a Chicago suburb, which was for years a farming community. During the past 4 years the teaching has been subdivided into departments of horticulture, plants and propagation, including forestry, agriculture, molds and blights, floriculture, pollination, window gardens, etc., represented by committees of teachers, each group specializing in the department to which it was assigned. The publications in the library on nature study are listed and the school garden work is described.

Home work for winter months for canning-club girls of Tennessee, LOUISE G. TURNER (*Col. Agr. Univ. Tenn., Ext. Div. Pubs. 2 (1914), pp. 12, figs. 2; 3, pp. 16*).—The first bulletin discusses kitchen rules, setting the table, and beverages, and the second cereals and breads.

Homemakers' clubs for negro girls, J. L. SIBLEY (*South. Workman*, 44 (1915), No. 2, pp. 81-86, figs. 6).—This is an account of the negro girls' gardening, domestic science, and sanitation club work conducted in 10 counties in Alabama with funds provided by the General Education Board, and in Macon County with funds provided by the extension department of Tuskegee Institute. The work was under the direction of the state supervisor of negro rural schools. Ten community centers in each county were visited each week.

MISCELLANEOUS.

Yearbook of the Department of Agriculture, 1914 (*U. S. Dept. Agr. Yearbook 1914*, pp. 715, pls. 53, figs. 45).—This contains the report of the Secretary of Agriculture, previously noted (E. S. R., 32, p. 795): 22 special articles abstracted elsewhere in this issue; and an appendix containing a directory of the agricultural colleges and experiment stations and the state officials in charge of agricultural work, and statistics of the principal crops, farm animals and their products, the federal meat inspection, agricultural statistics from the census of 1910, and imports and exports of agricultural products.

A report on the work and expenditures of the agricultural experiment stations during the fiscal year ended June 30, 1913 (*U. S. Dept. Agr., Rpt. Work and Expenditures Agr. Expt. Stas., 1913*, pp. 110, pls. 6).—This includes the usual report on the work and expenditures of the agricultural experiment stations in the United States, including Alaska, Hawaii, Porto Rico, and Guam, together with detailed statistics compiled from official sources as to the organization, lines of work, revenues, additions to equipment, and expenditures of the stations.

Twenty-sixth Annual Report of Maryland Station, 1913 (*Maryland Sta. Rpt. 1913*, pp. XX+271, figs. 64).—This contains the organization list; a report by the director on the organization, work, and publications of the station; a financial statement for the fiscal year ended June 30, 1913; and reprints of Bulletins 168-177, previously noted.

Work and progress of the agricultural experiment station for the year ended June 30, 1914 (*Missouri Sta. Bul. 131* (1915), pp. 441-509, figs. 8).—This contains the organization list, a report of the director on the work and publications of the station and the work of the college extension service, and a financial statement for the station for the fiscal year ended June 30, 1914. The experimental work reported is for the most part abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (*Washington Sta., West. Wash. Sta. Mo. Bul.*, 3 (1915), Nos. 2, pp. 16, fig. 1; 3, pp. 8).—These numbers contain brief articles on the following subjects:

Vol. 3, No. 2.—Why Tolerate Mesquite, by H. L. Blanchard; Some Summer Fruit Insect Pests, by J. L. Stahl; Comb Honey, by J. W. Ware; Finishing Poultry for Market, by V. R. McBride; Concerning the Rainfall, by E. B. Stoukey; and Bacterial Gummosis of Cherries, by H. L. Rees.

Vol. 3, No. 3.—Saving Hay Crops, by H. L. Blanchard; Extracted Honey, by J. L. Ware; and Production and Handling of Market Eggs, and Preserving Eggs, by V. R. McBride.

[**Index to Wyoming Station publications, 1907-1914**], J. E. ANDERSON (*Wyoming Sta. Index Bul. E* (1915), pp. 94).—This contains lists of the publications of the station from its organization to July 1, 1914, and a combined subject and author index to Bulletins 76-98 and annual reports from 1908 to 1913, inclusive, continuing previous work (E. S. R., 19, p. 695).

NOTES.

Connecticut College.—Dr. A. F. Blakeslee, professor of botany and genetics, has been appointed plant geneticist at the Carnegie Station for Experimental Evolution, beginning October 1.

Kansas College and Station.—The graduating class this spring numbered about 200, of whom 46 received the bachelor's degree in agriculture and 65 that in home economics. A course in plant breeding was offered in the summer school for the first time. The fifth school for rural leaders gave special prominence to rural sociology.

Dr. Paul S. Welch, who has been connected with the investigations of staple crop insects in the station, is now giving his full time to college work as assistant professor of entomology. W. P. Hayes, assistant in zoology in the college, has been added to the station staff as assistant in the staple crop insect investigations. L. E. Hobbs, D. V. M., assistant in hog-cholera work in the station, has resigned and has been succeeded by O. E. Strodman. E. P. Harling has been appointed seed analyst and R. H. Needham assistant chemist. G. A. Gilbert, instructor in dairy husbandry in the college and assistant in dairy manufactures in the station, has resigned.

Maine University and Station.—H. D. Lucas, assistant chemist in the station, resigned July 1 and has been succeeded by Walter H. Rogers, a 1915 graduate of the university.

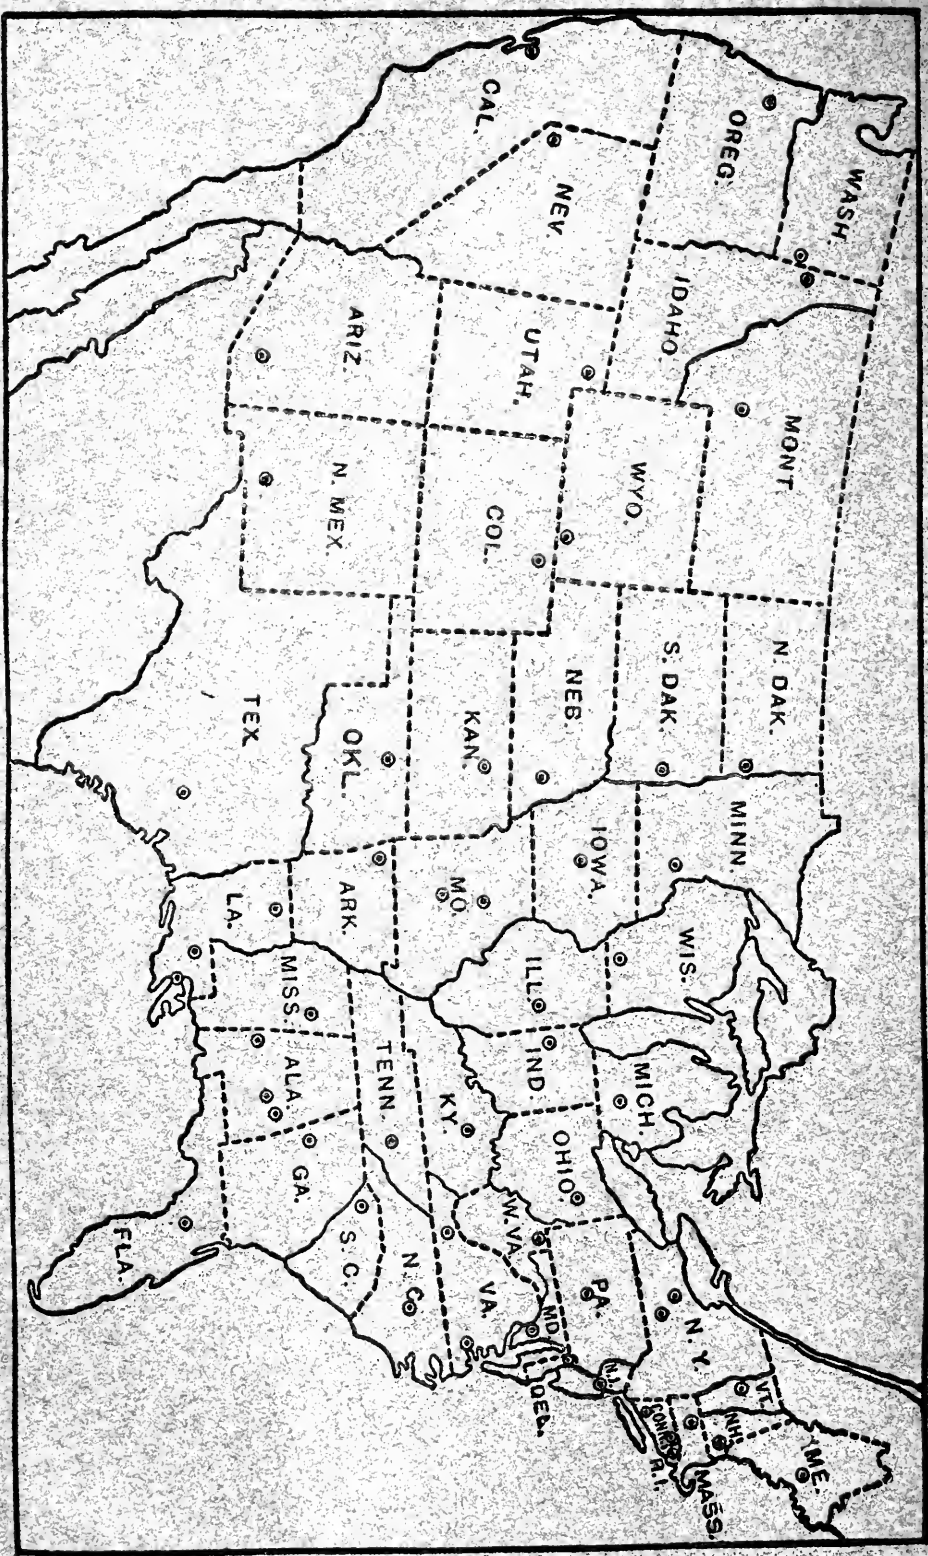

Massachusetts College and Station.—A bequest of \$4,000 for assisting worthy students, made in the will of Major Henry E. Alvord several years ago, has now become available.

John Phelan, of the University of Wisconsin, has been appointed professor of rural sociology. Arnold P. Sturtevant, recently connected with a commercial laboratory in Philadelphia, has been appointed assistant in animal pathology beginning July 1 and will give special attention to studies of bee diseases.

New Mexico College and Station.—Dr. E. P. Humbert, station agronomist, has been appointed dean of agriculture, beginning July 1. Roland Harwell resigned as assistant agronomist May 1 to become county agriculturist for Torrance County, and was succeeded June 1 by J. G. Hamilton, a 1915 graduate of the college. R. L. Stewart resigned July 1 as assistant animal husbandman, and was succeeded by E. J. Maynard, also a 1915 graduate of the college. A. B. Fite, another 1915 graduate, has been appointed assistant horticulturist, beginning July 1. C. P. Wilson, formerly station stenographer, has been appointed editor of agricultural publications for the station and the extension division in addition to his previous duties as extension secretary. Dr. R. F. Hare, station chemist since 1904, resigned July 1.

CONTENTS OF VOL. XXXIII, NO. 4.

	Page.
Editorial notes:	
The Berkeley convention of the Association of American Agricultural Colleges and Experiment Stations	301
The preparation of men for teaching and research in agriculture	303
The effective correlation of station and extension work	306
Some other problems before the association	307
Recent work in agricultural science.....	310
Notes.....	399

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemical methods, edited by Adberhalden.....	310
The proteid substances of barley, Schjerning.....	310
The carbohydrates of vegetables.—IV. Carbohydrates of Savoy cabbage, Busolt.....	310
Influence of temperature and time on reducing sugar of potatoes, Baudrexel.....	310
Evidence of the occurrence of a hexose sugar in normal milk, Jones.....	311
Gossypol: A toxic substance in cotton seed, Withers and Carruth.....	311
The chemical nature of catalase, Waentig and Gierisch.....	311
Tests on catalase solutions with proteolytic and peptolytic ferments, Winkler.....	311
On vicine, Levene.....	311
A starch-forming enzym from malt: Its action and application, Davis.....	312
The action of micro-organisms on betain, Ehrlich and Lange.....	312
Simplification of the determination of total nitrogen by colorimetry, Gulick.....	312
The estimation of ammonia by the boric-acid method, Winkler.....	312
Remarks on Winkler's work on the estimation of ammonia, Bernard.....	313
Solubility of mineral phosphates in citric acid, Robertson.....	313

	Page.
A convenient method for separating iron and aluminum, Borck.....	313
Copper sulphate of commerce and methods for copper, Mach and Lederle.....	313
The cupric reducing power of xylose and arabinose, Daish.....	314
Estimation of cellulose in flours, Lindet.....	314
Apparatus for determining fat in cheese, dry milk, cream, etc., Herramhof...	314
The measurement of diastase activity in plant extracts, Appleman.....	315
Estimates of cholesterol by gravimetric and colorimetric methods, Weston....	315
The use of the interferometer in agricultural investigations, Kappen.....	315
The burning quality of cigar wrapper, III, Tijnstra.....	316
Studies on fruit juices, Gore.....	316
When, what, and how to can fruits and vegetables in the home, Carver.....	318

METEOROLOGY.

The rainfall régime of the several States, Wallis.....	318
The distribution of the rainfall in the western United States, Wallis.....	319
Influence of western yellow pine forest on snow, Jaenicke and Forester.....	319
Atmospheric influence on evaporation and its direct measurement, Livingston.	320
Monthly weather periodicity, Köppen.....	320
Influence of the moon on weather.....	320
Monthly Weather Review.....	320
Climatological data for the United States by sections.....	321
Meteorological observations at Massachusetts Station, Ostrander et al.....	321

SOILS—FERTILIZERS.

[Soil analyses], Hume.....	321
Cola's osmotic theory of edaphism, Cavers.....	321
Nature and methods of extraction of the soil solution, Stiles and Jørgensen....	322
The difficulty with which soils are moistened, Ehrenberg and Schultze.....	322
The ground water, Grohmann.....	322
Water movement in peat, Franklin.....	322
Antagonism between anions as affecting barley yields, Lipman and Gericke..	323
Antagonism between anions as affecting nitrogen fixation, Lipman and Burgess.	323
Relation of carbon bisulphid to soil organisms and plant growth.....	323
New experiments on alkali soil treatment, Lipman and Sharp.....	324
The dead moor on Steinhude Lake, Birk.....	324
Management of marsh soils.....	325
The results of technical moor utilization, Keppeler.....	325
Changes in a sterile sand by cropping, Blanck.....	325
Management of sandy soils.....	325
Farm manures, Beavers.....	325
Farm manure, Olson.....	325
Chemical preservation of manure, Maignen.....	325
Manuring of farm crops.....	326
Influence of organic substances on nitrogenous compounds in the soil, Gerlach..	326
Conditions of Chilean nitrate industry, Havens.....	326
The fixation of atmospheric nitrogen, Landis.....	326
Fixation of atmospheric nitrogen, Summers.....	326
Is loss of lime from soil increased by kainit? Gerlach and Veckenstedt.....	326
Manuring experiments with manganese carbonate in Italy, d'Ippolito.....	326
Wool and leather wastes, Russell.....	327
A note on the export of manures from India.....	327

AGRICULTURAL BOTANY.

Inorganic plant poisons and stimulants, Brenchley.....	327
Toxic effect of iron and aluminum salts on clover seedlings, Ruprecht.....	328
Effect of salicylic aldehyde on plants in soil and solution cultures, Skinner...	328
The decrease of permeability due to certain bivalent cations, Osterhout.....	328
The production of anthocyanins and anthocyanidins, II, Everest.....	329
Oxidation by catalysts of organic and inorganic origin, Ewart.....	329
Cytological studies of <i>Azotobacter chroococcum</i> , Bonazzi.....	329
Physiological studies of <i>Bacillus radicicola</i> of Canada field pea, Prucha.....	329
Negative heliotropism of urediniospore germ tubes of <i>Puccinia thamni</i> , Fromme.	330
Flora of Vermont.....	330

FIELD CROPS.

	Page.
Field experiments, 1914.....	330
[Field crop studies].....	331
[Breeding experiments with cereals], Hume.....	331
Vascular bundles and their significance in lodging of cereals, Moldenhawer.....	332
Effect of different times of plowing small-grain stubble in Colorado, Grace.....	332
Meadows and pastures, Voorhees.....	332
Growing hay in the South for market, Piper, McClure, and Carrier.....	332
Corn, milo, and Kafir in the southern Great Plains area, Chilcott et al.....	332
Forage crops, Allen.....	333
The effect on a crop of clover of liming the soil, Morse.....	333
Hard clover seed and its treatment in hulling, Harrington.....	334
Improvement of the flax crop by propagation from selected plants, Hunter.....	335
Investigations on hops.—III, Pollination and fertilization processes, Winge.....	335
Spraying and dusting white potatoes, Headlee.....	336
Potato spraying experiments at Rush in 1914, Stewart.....	336
Mulched potatoes for seed purposes in eastern Nebraska, Howard.....	336
Potato seed certification in Wisconsin, Milward.....	336
Results of four years' experiments with sugar cane, Rosenfeld.....	336
Local fertilizer experiments with sweet potatoes, Duggar and Williamson.....	336
Irrigation practice in rice growing, Haskell.....	337
Growing hard spring wheat, Ball and Clark.....	337
Wheat silage, Shinn.....	337
Control of tumbling mustard, Adams and Hunter.....	337

HORTICULTURE.

Progress in plant breeding, Hansen.....	337
Mushrooms, edible and poisonous, Babcock.....	338
[Horticultural investigations at the Umatilla experiment farm, 1914], Allen.....	338
The influence of grass upon the growth of orchard trees, Barker.....	339
Pruning, Merrill.....	339
New developments in spray materials, Scott.....	339
New developments in spraying materials, Scott.....	340
Farm apple storage, Cummings and Lombard.....	340
Report of cranberry substation for 1914, Franklin.....	341
State bog report, Franklin.....	342
[Cranberry investigations].....	342
The avocado in California.—I, Culture, production, and marketing, Condit.....	342
Botanical characters of the leaves of the date palm, Mason.....	342
Mangoes in Florida, Rolfs.....	342

FORESTRY.

Forest planting in Vermont as an investment, Hawes.....	342
The cypress and juniper trees of the Rocky Mountain region, Sudworth.....	343
Caoutchouc, Ultee.....	343
Cinchona culture, Groothoff.....	343
Union of an oak and a birch, Davis.....	343
Union of an oak and a beech, Hollick.....	343
Notes on the germination of some tree and shrub seeds, Kinzel.....	343
Town sewage and house garbage as a forest manure, Schwappach.....	343
Forest administration in Western, Eastern, and Kumaun Circles, Billson et al.....	344
Report of forest administration in the Punjab for 1913-14, McIntosh.....	344
The production of lumber in 1913.....	344

DISEASES OF PLANTS.

[Investigations in plant diseases].....	344
Lightning injury to potato and cotton plants, Jones and Gilbert.....	345
Relation between <i>Puccinia graminis</i> and plants resistant to its attack, Stakman.....	345
The relation of grass rusts to the cereal rust problem, Stakman.....	345
The ascigerous stage of <i>Helminthosporium teres</i> , Johnson.....	345
Some facts of the life history of <i>Ustilago zeæ</i> , Piemeisel.....	345
Third progress report on <i>Fusarium</i> -resistant cabbage, Jones.....	346
Relation of temperature to infection by <i>Fusarium congenitans</i> , Gilman.....	346

	Page.
Cotyledon infection of cabbage seedlings by bacterial black rot, Drechsler.....	346
A disease of clover caused by a new species of <i>Colletotrichum</i> , O'Gara.....	346
A disease of Irish potato caused by a new <i>Colletotrichum</i> , O'Gara.....	346
"Spindling sprout" of potatoes, Hall.....	346
A contribution to the life history of <i>Spongospora subterranea</i> , Kunkel.....	346
Soil stain and pox, two little known diseases of the sweet potato, Taubenhau.....	347
Some important leaf diseases of nursery stock, Stewart.....	347
A promising new fungicide, Scott.....	347
Apple cankers and their control, Hesler.....	347
Field studies of apple rust, Giddings and Berg.....	348
Apple rots, Brooks, Fisher, and Cooley.....	348
York spot and York skin-crack, Reed.....	348
Orchard experiment with Jonathan spot rot in 1914, Martin.....	348
Jonathan spot, bitter pit, and stigmomose, Brooks and Fisher.....	348
Stigmomose: A disease of fruits, Waite.....	349
Common diseases of apples, pears, and quinces, Cook.....	349
Common diseases of the peach, plum, and cherry, Cook.....	349
Twig and leaf infection of the peach by <i>Cladosporium carpophilum</i> , Keitt.....	349
Fungus-host relationship in black knot, Gilbert.....	349
The perfect stage of the fungus of raspberry anthracnose, Burkholder.....	350
[Fungus diseases of cranberries], Franklin.....	350
Rhizoetonia in America, Peltier.....	350
An anthracnose of <i>Asclepias speciosa</i> caused by a new <i>Colletotrichum</i> , O'Gara.....	350
Some effects on chestnut trees of the injection of chemicals, Rumbold.....	350
Notes on <i>Cronartium comptonia</i> and <i>C. ribicola</i> , Spaulding.....	351
Observations on the pathology of the jack pine, Weir.....	351
A new leaf and twig disease of <i>Picea engelmanni</i> , Weir.....	351

ECONOMIC ZOOLOGY—ENTOMOLOGY.

[Report on insect pests].....	351
Potato insects, Webster.....	352
[Work with cranberry insects in 1914], Franklin.....	352
The control of citrus insects, Quayle.....	353
Control of dried-fruit insects in California, Parker.....	353
Some external parasites of poultry, especially Mallophaga, Herrick.....	353
A new wheat thrips, Kelly.....	354
Control of the citrus thrips in California and Arizona, Horton.....	354
A new species of North American Tingitidæ, Heidemann.....	355
The eggplant lace-bug, Fink.....	355
Leafhoppers of Maine, Osborn.....	356
The sharp-headed grain leafhopper, Gibson.....	356
Influence of soil moisture on increase in sugar-beet root louse, Parker.....	357
The Hessian fly, Headlee.....	357
Fly baits, Buck.....	357
Control of the onion fly, Sanders.....	357
Insecticides for the control of the Colorado potato beetle, Smith.....	358
The southern corn-leaf beetle, Kelly.....	358
North American Cerambycidæ.—Larvæ of the Prioninæ, Craighead.....	360
The roundheaded apple-tree borer, Brooks.....	360
Some sugar-cane root-boring weevils of the West Indies, Pierce.....	360
Descriptions of new Hymenoptera, IX, Crawford.....	360

FOODS—HUMAN NUTRITION.

[Food and drug topics], Ladd and Johnson.....	360
Digestibility of proteins of cereals, legumes, and potato flour, Rammstedt.....	361
Influence of environment on wheat in India, III, Howard et al.....	361
Banana meal a substitute for flour, Monaghan.....	361
Digestive disturbances following the use of war bread, von Noorden.....	361
Bread seasoning, Maurizio.....	361
Proso and kaoliang as table foods.....	361
The nutritive value of the avocado, Jaffa.....	362
Unfermented grape juice, McGill.....	363
The preservation of meat, Copaux and Kling.....	362
Bacterial content of desiccated egg, Ross.....	362

	Page.
Cooking fats in South America.....	362
The use of hardened fats for food purposes, Thoms and Müller.....	362
Use of hydrogenized fish oil in oleomargarin manufacture, Klimont and Mayer..	363
Report on food and drug products, 1914, Street.....	363
Twenty-first annual report of the Dairy and Food Commissioner of Michigan..	363
The Food and Drugs Act.....	364
Food—what it is and does, Greer.....	364
Physics of the household, Lynde.....	364
[Popular nutrition bulletins].....	364
The public feeding of elementary school children, Winder.....	364
A standard dietary for an orphanage, Jaffa.....	365
Feeding men in camps, Fisher.....	365
A modern small-sized construction camp with costs of feeding men, Robinson..	365
Campaign rations for the army, Basset.....	365
Beri-beri, Vedder.....	365
Relationship of beri-beri to glands of internal secretion, Funk and Douglas...	365
The harmlessness of vinegar eels in the human and animal organism, Wüstenfeld	366
Metabolism of white races living in Tropics.—I, Protein metabolism, Young...	366
Gastrointestinal studies.—VII, Utilization of protein, Foster and Hawk.....	366
Circulation of the blood in man at high altitudes, II, Schneider and Sisco.....	366
Some metabolic influences of bathing in the Great Salt Lake, Mattill.....	367
Healthy atmosphere, Hill.....	367

ANIMAL PRODUCTION.

Influence on growth of rations restricted to corn or wheat, Hart and McCollum..	367
Value of proteins from different sources.....	367
Effect of rations from single plant sources.....	367
Acidosis and its relation to protein storage, Steenbock et al.....	368
Relation of different fats to animal growth.....	368
Effect of poison on germ cells.....	368
Physiology of reproduction.....	369
Assumption of male secondary characters by a cow, Pearl and Surface.....	369
Sex ratios in pigeons, Cole and Kirkpatrick.....	369
Studies on inheritance in pigeons.—II, The feather pigments, Lloyd-Jones...	371
Inspection of feeding stuffs, Clark.....	371
Analyses of feeding stuffs, Wessels et al.....	371
The law regulating the sale of concentrated feed stuffs in Texas, Youngblood..	371
Cattle feeding.—X, Winter steer feeding, 1913-14, Skinner and King.....	371
Corn silage and alfalfa hay for beef production, Bliss and Lee.....	373
Raising calves on skim milk, Reed.....	374
Sheep feeding.—IV, Fattening western lambs, 1913-14, Skinner and King...	374
Specific effects of rations on the development of swine, Forbes et al.....	375
Pork production, Snyder.....	376
Profitable hog feeding, Hislop.....	379
Alfalfa pasturing experiment, Allen.....	379
Rape pasture for pigs in cornfield. Kaoliang for pigs, Wilson.....	380
A metabolism crate for swine, Forbes.....	380
Rations for growing and fattening roasters and capons, Buss.....	380
Essentials for growth of chicks, Whitaker.....	381
Wild fowl and poultry propagation.....	381

DAIRY FARMING—DAIRYING.

[Milk production].....	381
The value of nitrogen of alfalfa hay for milk production.....	382
Dairy problems.....	382
Pasteurizing milk in bottles and in bulk, Ayers and Johnson, jr.....	382
Leucocytes in milk.....	382
Do low scores always mean poor milk? Hall.....	382
How to produce cream that makes good butter, Hunziker and Ogle.....	383
Variations in the tests for fat in cream and skim milk, Guthrie and Supplee...	383
The Babcock test and its application, Hundertmark.....	383
The creamery and testers' license law.—Report for 1915, Hunziker and Ogle..	383
Markets and prices of Wisconsin cheese, Hibbard and Hobson.....	383

VETERINARY MEDICINE.

	Page.
Annual report veterinary research, 1913-14.....	384
Protective enzymes, immune sera, and anaphylaxis, Pearce and Williams	385
Studies on so-called protective ferments, I, Bronfenbrenner et al.....	385
A note on the preparation of bacterial vaccine, Stone.....	386
Detection of anthrax with precipitation method, Schütz and Pfeiler.....	386
Vaccination against anthrax according to Sobernheim's method, Engel.....	387
Blood examinations in combating glanders, Nevermann.....	387
The eradication of glanders in Prussia by the blood test, Nevermann.....	387
Vaccination tests with serum against rabies, Pfeiler and Kapfberger.....	387
Tuberculosis diagnosis with complement fixation Bierbaum and Berdel.....	387
Microscopical detection of tubercle bacilli in open tuberculosis, Meyerhoff....	387
Sampling lung mucus from bovines for diagnosing open tuberculosis, Scharr....	387
Some observations on the tuberculin test, Jowett.....	387
A remedy for clover bloat, Healy and Nutter.....	388
Thiele's hog cholera remedy "544".....	389
Poultry diseases.....	389
Factors in combating fowl tuberculosis, Van Es.....	389

RURAL ENGINEERING.

The use of water in irrigation, Fortier.....	389
Treatise on engineering studies and works for water transportation, Engels.....	390
Report of the State engineer, Parshall.....	390
[Irrigation and other experiments, Umatilla project, Oregon, 1914], Allen.....	390
Irrigation of plains of Kep, Voi, Bao-Loc, Pins, and Phu-Lang-Thong, Rouen.....	391
Water regulation in the different water districts of Java and Madoera.....	391
Surface water supply of Missouri River basin, 1913.....	391
Surface water supply of the lower Mississippi River basin for 1913.....	391
Water resources of Rio Grande basin, 1888 to 1913, Follansbee, Dean, et al....	391
Report of progress of stream measurements for 1913, Sauder et al.....	391
Pumping water by means of steel windmills, Müller.....	391
Irrigation with fresh water from the sea, Meynihan.....	392
Proceedings of tenth annual meeting of Iowa State Drainage Association.....	392
Alkali and water-logged lands.....	392
West Tennessee gullied lands and their reclamation, Maddox.....	392
The law of highways, MacKenzie.....	393
Report of the State commission of highways.....	393
Road models.....	393
Surfaces or floors for bridges, Older.....	393
Use of the Abney hand level, Hickerson.....	393

RURAL ECONOMICS.

Principles of rural credits, Morman.....	393
Agricultural organizations in European countries, Pearson.....	394
[Cooperation in Switzerland].....	394
The social anatomy of an agricultural community, Galpin.....	394
[The dwellings of agricultural workers], Durand and Sanchez.....	394
Report on public administration in relation to agriculture, Garner.....	395
Negroes in the United States.....	395
Live stock [in Costa Rica].....	395
Agricultural statistics of Sweden.....	395
Agriculture in Algeria.....	395
[Agricultural statistics of Egypt].....	395
[Chinese agriculture].....	395
[Agriculture in Japan].....	395
[Agriculture of New Zealand].....	395
Monthly crop report.....	395
Statistical notes on cereals.....	396
[Prohibited exportation of agricultural products].....	396

AGRICULTURAL EDUCATION.

[Progress in agricultural education in Manitoba].....	396
Report of the department of agriculture for 1912.....	396
The use of land in teaching agriculture in secondary schools, Colvin.....	396

	Page.
Tenth acre gardening demonstration, Kirkpatrick.....	396
Agricultural extension service.....	396
[Agriculture and home economics in schools of New Hampshire], Whitcher....	397
[Instruction in agriculture, cooking, and sewing in Porto Rico].....	397
Education for the home, Andrews.....	397
Cooking in the vocational school as training for home making, O'Leary.....	397
Lesson plans for teachers in nature-study agriculture, Patterson and Dexheimer. [Rural school agriculture].....	397
Practical lessons in tropical agriculture, Book I, Clute.....	397

EXPERIMENT STATION RECORD.

VOL. XXXIII.

SEPTEMBER, 1915.

No. 4.

For the third time in its history the Association of American Agricultural Colleges and Experiment Stations this year held its convention on the Pacific coast. The first meeting there was at San Francisco in the summer of 1899 and the last previous one at Portland, Oregon, in 1909. This year members from the East and the Central West again journeyed across the plains and the mountains to meet with their colleagues of the West on their own field of action. The sessions were held at Berkeley in the spacious agricultural building of the University of California, August 11-13, 1915.

The meeting was generally considered a successful and satisfactory one from all points of view. The registration was unusually large—considerably over two hundred, the representation was very general from all parts of the country, and the attendance on the various sessions was good. Despite the attractions of the exposition the convention held the attention of the delegates, most of whom stopped at Berkeley, to a degree which showed the serious purpose of the meeting and the interest maintained in it. The number of special conferences was unusually large.

The convention was preceded by the summer meeting of the American Association for the Advancement of Science and the annual gathering of various distinctly agricultural associations, and it was followed by the meeting of the National Education Association. Rarely has so large a body of persons interested in education and research been brought together in a series of consecutive meetings.

While the convention took no action of outstanding importance, there were fully the usual number of matters of special interest to the land-grant colleges and the various departments of their work. The animated discussion of some of these matters showed the vital interest which surrounds them at this time, and in some instances a desire for greater opportunity for discussion than the limits of the sessions afforded.

The solidarity of the land-grant colleges was emphasized in the presidential address of President E. A. Bryan of the association, who pointed out the national character of these colleges, their common interests and purpose, and the place they have occupied in education. He described the line separating the old education from the new as represented by these institutions, which are to minister to our common welfare. They now comprise a national system of education, largely subsidized by the Federal Government and with certain prescribed relations to it. They have greater solidarity than any other class of institution.

President Bryan urged that unity should be maintained among the colleges of this great system—a balance, a coordination between them. Because together they constitute a national system of education he urged a closer relation of the national Bureau of Education to them in helping them to work out their mission; and he advocated a national Department of Education, presided over by a Secretary.

The U. S. Bureau of Education was represented on the program by Dr. S. P. Capen, who discussed the relation which the Bureau has sustained to the land-grant colleges. The specialist of the Bureau of home economics, Mrs. Henrietta W. Calvin, was also present and discussed that division of the work.

Dr. C. A. Duniway set forth the position of economic science in colleges of agriculture and mechanic arts. After pointing out the elementary character of the requirements in this line for graduation from most of these colleges, he emphasized the importance at this time of correlated courses in economics, in preparation for industrial life and citizenship.

The correlation of the college of agriculture of Ohio with other institutions in the State according to the plan previously noted,^a was described by Prof. Alfred Vivian. The plan has now been in operation for two years and has proved quite satisfactory. It stimulates both of the participating institutions, and it has some advantages for the student, permitting him to take his elementary course in small classes, often at less cost, and to be an alumnus of the arts college as well as of the university. It was explained that such students are found to more readily take up graduate work.

In an evening address, Dean Thomas F. Hunt, of California, gave an interesting and informing account of the agricultural institutions now in operation in that State, equal in area to the nine northeastern States and having all the problems of those States and some others. Instead of nine separate agricultural colleges and experiment sta-

^a Expt. Sta. Rec., 30, p. 397; 32, p. 798.

tions, as in that group of States, California has only a single organization, but it has eight centers of activity at present, three of which were designated as major centers and five as minor. The activity and the plans at each center or unit were set forth. Much interest was manifested by those who had not had opportunity to study the system, in this description of the manner in which the varied needs of the State are being met. A considerable number of the delegates took occasion to visit some of these units located away from the university.

The preparation of men for teaching and research in agriculture, and the means of securing it, was a live subject of consideration. This is recognized as one of the great problems of the day in the advancement of this agricultural work. It is common to each division of the undertaking and to every section of the country. The demand for workers has grown very rapidly, and the standards have advanced with the grade of the work now required of the institutions. The number of adequately prepared persons has not kept pace with this development. It was pertinent, therefore, that the subject should be one for extended discussion.

As bearing on the subject from the standpoint of the college as a preparatory agency, President A. Ross Hill reviewed the situation with reference to the service contemplated in the Nelson amendment. He showed from a canvass of the catalogues what the various colleges are attempting to do, and incidentally the inadequacy of their efforts. Not only is the provision inadequate but the colleges are not attracting or preparing the necessary numbers. The belief was expressed that probably all of the land-grant colleges combined are not training enough teachers to meet the needs of a single State. Dr. Hill urged the need of a propaganda to attract prospective teachers.

This paper resulted in a very interesting discussion, along a line which has heretofore not received much consideration by the association. Complaint was made by some of the difficulty of attracting persons to the field of agricultural teaching in view of the avenues open to them in other lines, especially agricultural extension. But, on the other hand, it was shown that the presentation of the larger field of the agricultural teacher had in some States inspired considerable numbers of persons to enter that field. In Minnesota, for example, there are one hundred and seventy schools teaching agriculture and it has been possible to get all the teachers needed, these being drawn from some twenty agricultural colleges. The opening up of an avenue for these teachers outside the school room in conducting community work has been a great incentive. These agricultural

teachers often become county agents, and the teaching experience has proved a fine training ground for them.

The preparation required for workers in the three general divisions of the agricultural work—college teaching, research or station work, and extension work—was considered in a set of papers presented before the college section; and the report of the standing committee on agricultural instruction dealt specifically with college courses for the preparation of extension workers.

The comprehensive report as to the preparation of extension workers was based on about a hundred replies to a questionnaire sent to agricultural educators, extension directors and others in charge of extension work, and others interested therein. The committee advocated that a considerable number of the agricultural colleges should offer undergraduate courses for the purpose, and that a few should make special provision for graduate instruction.

In one of the general sessions Dr. H. L. Russell described a plan for promoting advanced study through exchange with other colleges. This had in mind the postgraduate preparation of men from the institution, and the purpose of the plan as explained was to "avoid inbreeding" and to promote "cross breeding" with other institutions. Dr. Russell believed that not more than one-half of the permanent staff above the assistant grade should be chosen from the home institution. At the University of Wisconsin assistants are required to go elsewhere for advanced study, and to provide for this and meet the financial difficulty which often confronts young men an exchange relationship has been established with certain other colleges. This cooperative arrangement provides for mutual exchange of staff members, with opportunities afforded for study. The description of this plan developed so much interest that the paper was referred to the committee on college organization and policy, with a view to arranging for a consideration of its suggestions.

The station section had before it the question as to what the stations can do to encourage more men to fit themselves for advanced research. It developed out of the discussion that considerable is being done in a systematic way by some of the institutions to advance this end. One station encourages its younger men to take graduate work in the local university, allowing part time for the purpose; and it followed the practice of sending older men away to other institutions, allowing them to take their station projects with them and work upon them under salary from the station.

The practice of providing fellowships has become quite common. In some instances promising men are selected in the senior year and fellowships offered in return for special work of a research character.

Other institutions offer such fellowships for graduate students only. The value of this method in attracting workers is proving quite important. It enables the prospective employee to get a deeper insight into the spirit of research, and kindles an interest and a desire which are not aroused in the ordinary course of instruction. The acquiring by this means of something of "the living, breathing spirit of research"—of going beyond the boundaries of knowledge, presents the field in a new light and is one of the greatest sources of stimulation to young men.

While the chief purpose of this plan is usually educational, the immediate advantages to the station work are not to be overlooked. In an increasing number of institutions graduate students are being utilized in conducting the station investigations, and in some instances this is looked upon as an economical means of securing assistance. Some have gone so far as to divide their main theme or project into various parts which can be worked out independently and assigned to advanced students to be conducted under the general direction of the leader of the project. The real advantage of this to the station depends largely on the nature of the subject and on the men assigned to it. The right kind of graduate assistants may be a real help, as has often been found to be the case, but instances have also occurred in which men well recommended by other institutions have proved disappointing as graduate assistants.

Evidently the station work must not be contingent upon this type of service, or subordinated in any sense to the purpose of teaching. It is based on the plan of the university in making provision for graduate work, and it is well recognized as largely a phase of the teaching activity. As a teaching function the responsibility for it should rest usually with the college or university, and for that reason doubtless the college has in specific instances provided the fellowships. Unless there is some direct advantage or aid to the station, it will rarely be able to do more than a quite limited amount in this direction. But the community of interest among the stations in promoting more thorough preparation of men for research work makes efforts of this kind worth encouraging.

The salary attractions in other directions, especially under the development of the extension work, make the recruiting of the station staffs more difficult and present real obstacles in the way of inducing men to take long and expensive courses in preparation for research activity. The need of arousing zeal for creative work and the encouragement of promising young men in preparing for it can hardly escape the attention of the stations at this time.

The opportunities of the Graduate School were again referred to in the report of the committee on graduate study, and it was urged

that the younger men at the colleges and stations should avail themselves more largely of it. In emphasizing the importance of this the committee expressed the belief that college and station employees attending the school should be considered as on duty and that the time so occupied should not be deducted. The association endorsed this recommendation.

The effective correlation of station and extension work and the means of securing public recognition for that of the station was another live topic discussed in the station section. Considering the correlation of the two sets of workers from the standpoint of the extension director, Mr. Bradford Knapp suggested that the station men should go out enough to maintain contact with the farmers. They might exchange work to some extent with the extension men, especially in the preliminary stages of preparation for extending the results of station work in the field. Conferences between the two sets of workers, at least annually or semiannually, were advocated.

Prof. C. E. Thorne, speaking from the standpoint of the station director, pointed out that the experiment stations collectively are the source of the more exact knowledge with reference to factors which bear upon the progress of agriculture. They were organized to advance definite knowledge. They furnish the best means we have of reaching further into the unknown and of correlating and co-ordinating what is known. The teacher in the great outside must keep himself posted and in touch with the experiment station in his own State, and to some extent with the stations collectively.

In Ohio the station is extending the points of its work to various parts of the State, by maintaining branch stations. It is felt that the county agent is thus given an advantage by having available the help of these smaller agricultural farms, and that data of more local application can be secured and tested. Such arrangements will call for definite understanding, but will offer for men opportunity to work in both fields—on the local experiment farms and in the extension teaching.

Discussion of the best means of securing recognition and credit for station work through the extension staff brought out the fact that the attitude of the extension worker is a large factor in this matter, and that his closeness to the public affords a means of giving wide publicity to the station work and emphasizing its importance. The close contact which the stations formerly had with the public, through meetings, correspondence, personal visits, etc., will be diminished as the extension work is segregated and grows in extent. Obviously, the extension man can ill afford to claim to be the original source of the information he gives out, and the importance to his

work of maintaining the support for station activity should lead him and those in general charge of the extension enterprise to give full prominence and credit to the station.

A feeling was expressed that unless this is systematically done the stations will ultimately suffer, and that the individual extension worker will be magnified in importance to the detriment and crippling of the institution which has given him his strength and appeal. The statement was made that the agricultural colleges are now in the greatest danger they have ever been by reason of the large amounts of money being appropriated for this popular line of work; they must watch to see that the research activity is continued and that the money for it is provided.

The matter of publications again came forward for consideration. The report of the standing committee on extension organization and policy dealt with extension publications and their distribution, showing that already the subject is being considered in this newer division of the work. The diversity of these publications and the lack of system or of definite policy in some instances makes the subject one well worthy of study.

The form of publication of station work was one of the main topics on the program of the station section, and occupied an entire afternoon's session. The consideration embraced the annual report, the station bulletin, and the publication of technical investigations in the *Journal of Agricultural Research* and elsewhere outside the regular station series. Further reference to this discussion is contemplated in a later issue of the *Record*.

A subject which affects a very large proportion of the stations was brought forward in the report of the committee on station organization and policy. This report dealt with the relation which the experiment stations should sustain to various lines of control work. It showed that while fundamentally the stations are for acquiring information and extending the boundaries of knowledge, they have gradually become involved in a great variety of control and regulatory work, until the modern station has become a complex and somewhat heterogeneous organization. The advantages and disadvantages of this kind of work were reviewed, and its special appropriateness to the stations and the necessity for them to continue to exercise such governmental functions was brought into discussion.

The report of the committee was in a large sense preliminary. The subject is one which deserves discussion and the main purpose of the committee was in opening up the question. At its suggestion the station section will place the subject on its program for the next

meeting, in order to afford opportunity for wider consideration and the presentation of views. Ultimately it is expected the topic will be made one for a future report of the committee on station organization and policy.

The subject of experiment stations for engineering for mechanic arts came in for an unusual amount of consideration at the Berkeley meetings. The Land Grant College Engineering Association, which met in connection with the convention, held a symposium on engineering experiment stations, devoting two sessions to that subject. In his presidential address, President Bryan advocated the making of provision for such a system of stations, to round out the proper development of the educational movement started in the land-grant act of 1862.

In connection with a paper on the place of mechanic arts and engineering in the land-grant colleges, President R. A. Pearson expressed the need for investigation in the field of engineering, citing numerous examples of the problems awaiting such study and some results which have already accrued. He urged the desirability of establishing experiment stations for engineering, to do for that subject what the present existing system of stations has done for agriculture.

At one of the general sessions of the association, Hon. F. G. Newlands, Senator from Nevada, gave an address on the subject of federal aid to engineering experiment stations. In this he urged that the mechanic arts are not of less importance than agriculture, and present the same need for research activities. He favored the provision of appropriations for the purpose by the Federal Government, and advised that effort be directed to creating an intelligent sentiment and understanding in that direction.

On this point the association reaffirmed its belief in the desirability of engineering experiment stations and of securing appropriations therefor; and it instructed the executive committee to proceed in that direction whenever conditions were deemed advisable.

It will be apparent that the twenty-ninth convention of the association lacked nothing in variety of the topics discussed or in timeliness and importance. To the people of the East the meeting was well worth the trip across the continent; and to those of the West it was an opportunity which has come to them but rarely of meeting with their colleagues on their own ground. The interchange of benefit was undoubtedly mutual.

The trip gave those from the East a clearer insight into the conditions surrounding their agricultural colleagues of the West, the great size of the States they are attempting to serve, the diversity of conditions, and the consequent diversity of the problems of teach-

ing and of investigation. It also brought a realization of the rapid development of the institutions of the West, which is difficult to gain except by observation and contact.

A most remarkable change has taken place since the former California meeting. In equipment, support, personnel, and grade of work the institutions of the West have made great strides. Their success and the appreciation which has marked their growth is not only gratifying to the whole country but it is stimulating and inspiring, for it gives new evidence of the position agricultural work has attained and the nation-wide character of its forward movement.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemical methods, edited by E. ABERHALDEN (*Handbuch der Biochemischen Arbeitsmethoden*. Berlin: Urban & Schwarzenberg, 1915, vol. 8, pp. XIII+684, pl. 1, figs. 298).—The eighth volume of this work (E. S. R., 30, p. 201) deals with the following topics: Microscopical methods for determining molecular weights; measurement of oxidation and fermentation rapidity in cells, and some remarks on the technique of cell physiological investigations; methods of examining stomach contents; refractrometric methods for biological investigations; methods of accelerating seed germination, the growth of seedlings, and forcing; analysis of plant material (drying and total solid determination, pressing and extracting, and the treatment of the extracts); a supplement to previous chapters on sterilizing the higher living plants (E. S. R., 29, p. 408); the most important methods for preparing cell granulations in fixed objects; methods for studying the physiology of plant growth; quantitative methods for determining small amounts of tannin in plant juices; preparation of physiologically active amines by decarboxylation of amino acids; the analysis of the rarer elements; determining of ester-(i. e., fat)cleaving action of blood and other body fluids with the drop method; the raising of germ-free mammals; supplements to previous chapters on general chemical laboratory technique (E. S. R., 23, p. 410); a description of a scale which registers automatically weight decrease and weight increase; microscopic air analysis and its uses; microrespirometry; functional investigations on the lungs of man with gas analytical methods; the interferometric method for studying the defensive ferments; and mathematical methods in the biological sciences.

On the proteid substances of barley, in the grain itself and during the brewing processes, H. SCHJERNING (*Compt. Rend. Lab. Carlsberg*, 11 (1914), No. 2, pp. 45-105, pl. 1, figs. 6).—A review of the work noted (E. S. R., 32, p. 23), with a description of the material and methods used in the investigation.

Contribution to our knowledge of the carbohydrates of vegetables.—IV, The carbohydrates of Savoy cabbage, E. BUSOLT (*Jour. Landw.*, 62 (1914), No. 2, pp. 117-120).—Continuing the work previously noted (E. S. R., 31, p. 11) the author reports that he was able to obtain in crystalline form from 15 kg. of Savoy cabbage 15 to 16 gm. of mannit and 3.1 gm. of grape sugar. The amounts present in this vegetable are probably greater.

The influence of temperature and time upon the direct reducing sugar of raw potatoes and potato juice, A. BAUDREXEL (*Ztschr. Spiritusindus.*, 37 (1914), Nos. 16, pp. 225, 226; 17, pp. 238, 239; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 59, *Referatenteil*, p. 467).—In this investigation the influence exerted by the respiratory process upon the sugars present in potatoes was excluded by comminuting the potatoes by grating and pressing out the juice in filter bags. The sugar was estimated in the juice by Bertrand's method.

In the experiments made for the purpose of finding the most appropriate methods for obtaining potato juice, it was found that the potatoes which were

taken from storage where temperatures varying from 12 to 15° C. prevailed contained 29 per cent of glucose. By storing these potatoes for several days at 5 to 6°, one set of experiments showed an increase in glucose of 0.0283 per cent and in another of 0.0296 per cent per day of storage. The juices obtained from the potatoes were then kept at 3, 31, and 48° for various lengths of time. A marked increase in glucose was noted in all cases, the greatest production being at the higher temperatures. Glucose formation occurred most rapidly at the beginning of the storage process. The diastatic power of the juices was low, but greatest in the freshly obtained juices.

The bacteriological and chemical evidence of the occurrence of a hexose sugar in normal milk, H. M. JONES (*Jour. Infect. Diseases*, 15 (1914), No. 2, pp. 357-366).—Bacteriological and chemical evidence is presented which is said to indicate that milk normally contains a substance which reacts like dextrose.

Gossypol: A toxic substance in cotton seed.—A preliminary note, W. A. WITHERS and F. E. CARRUTH (*Science*, n. ser., 41 (1915), No. 1052, p. 324).—“We have separated from cotton-seed kernels a substance which appears to be identical with the substance which Marchlewski [*E. S. R.*, 11, p. 510] separated from crude cotton-seed oil and called gossypol. We have administered in various ways to rabbits gossypol as prepared by us and have found it toxic in every case. We have found, as did Marchlewski, that gossypol is quickly oxidized in an alcoholic solution of sodium hydroxid.

“In a previous paper from this station [*E. S. R.*, 23, p. 279] it was stated that ‘(alcoholic) alkaline treatment, very greatly diminishes, if it does not entirely remove, the toxic properties of the (cotton-seed) meal,’ and it was suggested that the beneficial effect ‘may be due to hydrolysis or to the formation of a sodium salt or to some other change not yet determined definitely.’ We now offer as an explanation that gossypol is a toxic substance and that its oxidation by an alcoholic alkali renders it nontoxic and thus diminishes, if it does not entirely remove, the toxic properties of cotton-seed meal.”

About the chemical nature of catalase, P. WAENTIG and W. GIERISCH (*Fermentforsch.*, 1 (1915), No. 2, pp. 165-195).—Catalase of liver (present to the extent of 0.3 per cent) is a water-soluble coagulable protein substance which was precipitated in the cold by mineral acids, especially nitric acid, but not by acetic acid. Heating caused an inactivation and the coagulum obtained showed mucin-like characteristics. It was precipitated by the so-called alkaloidal reagents and bromin water in an acetic acid solution. The well-known protein reactions were positive and the biuret test was obtained as a blue-violet coloration. The protein substance probably contains a sugar which can be identified by the Molisch test but not after hydrolysis by Fehling's solution. The quantity of mineral substances present in a catalase preparation can be considerably reduced without affecting the activity of the catalase, although it was found that iron and phosphoric acid were not removed by dialysis and were adsorbed by the active substance. It is doubtful whether these two constituents, especially iron, are an integral part of catalase. Purin bases could not be noted in the preparations.

Digestion tests on catalase solutions with proteolytic and peptolytic ferments, K. WINKLER (*Fermentforsch.*, 1 (1915), No. 2, pp. 105-130).—The ferment erepsin which is present in the intestine of vertebrate animals destroys catalase. This fact is said to justify the conclusion that catalase is a chemical substance protein-like in nature. Some data on ferments present in invertebrates (crabs, snails, etc.) are also included.

On vicine, P. A. LEVENE (*Jour. Biol. Chem.*, 18 (1914), No. 2, pp. 305-311).—“Vicine was discovered by Ritthausen (*E. S. R.*, 29, p. 501), who found that

the substance could be hydrolyzed into a hexose and into a basic substance which was named by him di-vicine. The exact nature of the base and the configuration of the sugar were not recognized by the discoverer of the substance. Schulze and Trier,^a on the basis of theoretical considerations, were the first to give expression to the assumption that vicine had the structure of a pyrimidin glucosid."

This article gives the results of investigations dealing with some of the principal points in the structure of the nucleo side of the substances. "The results point to the conclusion that vicine is composed of 4-6-dioxy-2-5-diamino-pyrimidin combined in glycosidic union with *d*-glucose."

On a starch-forming enzym from malt: Its action on hemicelluloses and its commercial application to brewing, C. B. DAVIS (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 2, pp. 115-118, figs. 8).—A new enzym capable of hydrolyzing the hemicelluloses of yeast and cereals was isolated from barley malt.

"Hemicellulase is precipitated by metals, metallic salts, alcohol, and tannin. Its enzymatic action is destroyed at an elevated temperature above its optimum, 90° C., at which its action is irrevocably changed. Its action is catalytic and hydrolytic on hemicelluloses, otherwise known as granulose, starch cellulose, amylocellulose, amylopectin, pentosans, and hexosans, transforming them permanently into gelatinized starch between the temperatures of 15° and 90° C., and transforming the jelly of hemicelluloses which react yellow to iodine to gelatinous insoluble starch, giving an intense blue reaction with iodine. . . . Hemicellulase is without action on nitrogenous compounds, such as proteids, albumin, peptone, etc."

The application of this finding to practical brewing conditions was pointed out.

About the action of micro-organisms on betain, F. EHRlich and F. LANGE (*Ztschr. Ver. Deut. Zuckerindus.*, No. 697, II (1914), pp. 158-171; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 21, *Referatenteil*, p. 193).—Betain is one of the nonsugar substances which is not removed during the separation and saturation of beet juices, and is found in the strontium molasses slops in amounts up to 15 per cent.

It was found that betain is not affected by the ordinary distillery, beer, and wine yeasts, although it serves as a source of nitrogen for other micro-organisms. In the presence of sugar or ethyl alcohol it is fermented by surface film-forming mycoderma and by mold fungi. When betain is assimilated by micro-organisms acid is usually formed. *Willia anomala*, when grown in a betain solution, leads to the formation of glycollic acid. In a symbiotic culture of yeast and mold fungi, trimethylamin is produced, and from the latter, ammonia. Neither substance, however, can be detected because they are quickly synthesized to proteins. It is only possible with a few molds, as, for example, *Penicillium glaucum* and other related varieties, to detect ammonia in appreciable amounts.

A simplification of the determination of total nitrogen by colorimetry, A. GULICK (*Jour. Biol. Chem.*, 18 (1914), No. 3, pp. 541-547, fig. 1).—It has been found possible to improve and abbreviate the Folin-Farmer colorimetric nitrogen method by avoiding the aspiration of the products of oxidation. The method is said to be rapid to conduct, reliable, and simple.

The estimation of ammonia by the boric acid method, L. W. WINKLER (*Ztschr. Angew. Chem.*, 27 (1914), No. 94, *Aufsatzteil*, pp. 630-632, fig. 1).—In order to study the conditions under which the method operates, tests were

^a Hoppe-Seyler's *Ztschr. Physiol. Chem.*, 70 (1910-11), No. 2-3, pp. 143-151.

made with pure dried ammonium chlorid dissolved in water with the aid of a few drops of hydrochloric acid.

In using the boric acid method in the Kjeldahl procedures it is advisable to use a large excess of boric acid in the distillate collecting flask—i. e., 10 gm. of boric acid in 100 cc. of water for from 200 to 300 cc. of distillate. If the distillate amounts to only 100 cc. or less, 5 gm. of boric acid should be used.

The ammonia present is to be titrated with the standard hydrochloric acid solution, and not, as inadvertently stated in a previous abstract (E. S. R., 31, p. 108), the excess of boric acid. For this purpose the author recommends the employment of tenth-normal or fifth-normal hydrochloric acid solution, but discourages the use of sulphuric acid. If Congo red is used the solution to be titrated should be perfectly cool.

Remarks on L. W. Winkler's work on the estimation of ammonia with the boric acid method, E. BERNARD (*Ztschr. Angew. Chem.*, 27 (1914), No. 102, Aufsatzteil, p. 664).—The boric acid method is deemed rapid and convenient and yields very accurate results.

The solubility of mineral phosphates in citric acid, G. S. ROBERTSON (*Jour. Soc. Chem. Indus.*, 33 (1914), No. 1, pp. 9-11; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 64-65, Referatenteil, p. 506).—Determining in the usual manner citric acid soluble phosphoric acid in mineral phosphates destined for fertilizers is said to yield erroneous results. A single extraction with citric acid will not suffice and repeated extraction will dissolve almost all the phosphorus present in the fertilizer. The yields obtained with mineral phosphates on experimental plats are said to be as good as those given with slag or with bone meal.

A convenient method for separating iron and aluminum, H. BORCK (*Chem. Ztg.*, 38 (1914), No. 1, p. 7, fig. 1; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 29, Referatenteil, p. 249).—The method depends upon the volatilization of the iron from a mixture of iron and aluminum oxids by heating in hydrochloric acid through which a current of air is being passed. It will yield constant results only when a quartz boat is used.

Copper sulphate of commerce and methods for determining copper therein, F. MACH and P. LEDERLE (*Landw. Vers. Stat.*, 84 (1914), No. 1-2, pp. 129-143).—The fact that a sample of copper sulphate has a satisfactory appearance is not sufficient evidence of its value for spraying purposes. The Windisch method^a for determining copper with sodium hypophosphite yielded low results, despite the fact that the filtrate from the reduced copper does not give a reaction with either ammonia or potassium ferrocyanid. Better results were obtained when the copper reduced by sodium hypophosphite was collected in an Allihn tube instead of roasting the precipitate as suggested by Windisch, but this method, unless modified, is of value only when speedy results are desired. Rhead's^b and Moser's^c methods were tried and also found unsatisfactory.

The following method, which embodies some of the essentials of the Rhead and Moser methods, is recommended: Dissolve 10 gm. of the copper sulphate in approximately 200 cc. of hot water, render slightly alkaline with ammonium hydroxid, oxidize the ferrous iron with about 5 cc. of a 2 per cent hydrogen peroxid solution (this is adequate for salts containing 2 per cent ferrous sulphate), keep the solution at the boiling point for two minutes, and filter off the ferric hydrate. Wash the precipitate, dissolve in a little hot hydrochloric acid, reprecipitate the iron with ammonia, filter, and add the washings therefrom to the original solution. Make the iron-free solution slightly acid with

^a *Ztschr. Analyt. Chem.*, 52 (1913), No. 1, pp. 1-13.

^b *Jour. Chem. Soc. [London]*, 89 (1906), II, pp. 1491-1495.

^c *Chem. Ztg.*, 36 (1912), No. 117, pp. 1126, 1127.

hydrochloric acid and fill to the 1,000 cc. mark. To 25 cc. of the same (representing 0.25 gm. of copper sulphate) add from 10 to 20 cc. of hydrochloric acid (specific gravity 1.125), heat to the boiling point for one minute, and stopper with a rubber which contains two glass tubes which reach half way to the bottom of the flask. Connect one of the tubes with a carbon dioxid generator and allow a strong stream of gas to pass through the flask. Cool, rapidly rotating the flask, and add 5 cc. of a 10 per cent potassium sulphocyanid solution and two drops of a decinormal iron chlorid solution. Pass a stream of carbon dioxid through a tube inserted in the mixture, and titrate with a decinormal titanium trichlorid solution until a milky white color is obtained.

Methods of estimation of carbohydrates.—III, The cupric reducing power of the pentoses—xylose and arabinose, A. J. DAISH (*Jour. Agr. Sci. [England]*, 6 (1914), No. 3, pp. 255-262, figs. 2).—Tables are given to show that the reducing power of arabinose and xylose are almost identical. For practical purposes, when working with the unknown pentoses in plant extracts, it is considered probable that no large error will be incurred by taking as the divisor the average value for arabinose and xylose corresponding with the weight of cuprous oxid dealt with. The reducing powers of these two pentoses differ only very slightly from that of dextrose, the divisors for these three sugars for 100 mg. of sugar being, respectively, 2.536, 2.49, and 2.538. See also a previous note (*E. S. R.*, 32, p. 807).

Estimation of cellulose in flours with a special regard to their degree of grading, L. LINDET (*Ann. Falsif.*, 7 (1914), No. 66, pp. 169-171).—The method for determining cellulose in noting the extent to which the flour under examination had been bolted is as follows:

Ten gm. of flour from which the fat has been removed by either benzin or ether is treated in a beaker glass with 400 cc. of hydrochloric acid (specific gravity 1.025), boiled for one-half hour, and to the mixture is added 50 cc. of a 10 per cent solution of aluminum sulphate. The aluminum sulphate is then converted into an hydroxid with ammonia, the precipitated aluminum hydroxid which engulfs the cellulose particles collected on a filter, washed, and transferred from the filter to a flask or conical vessel, sodium carbonate solution (10 gm. per 100 cc. liquid) added gradually, and the mixture heated to 100° C. for one hour. The precipitate is then acidified with hydrochloric acid, made alkaline with ammonia, collected on a tared filter, and washed with dilute hydrochloric acid. After drying and weighing, the precipitate of aluminum cellulose is incinerated and weighed again. The quantity of ash found is deducted from the original weight and calculated as cellulose to 100 gm. of flour.

Dr. Herramhof's fat tester.—An apparatus for determining fat in cheese, dry milk, cream, etc., in practice, HERRAMHOF (*Molk. Ztg. [Hildesheim]*, 23 (1914), No. 36, pp. 677-679, fig. 1).—The apparatus employed consists of two parts, a flask which receives the cheese to be tested and the butyrometer proper. The outer wall of the mouth of the flask and the inner wall of the butyrometer are so ground as to form a sealed joint. The butyrometer is graduated to 0.5 per cent.

In the test 2.5 gm. of cheese is weighed into the flask and 6 cc. of sulphuric acid (specific gravity 1.5) is added. The flask and contents are heated on an asbestos plate until the cheese is completely dissolved, and 16.5 cc. of sulphuric acid (specific gravity 1.5) and 1 cc. of amyl alcohol are added. The butyrometer attachment is then placed on the flask and the apparatus kept for about one-half minute on the hot plate. After going through the other details of the procedure, the butyrometer attachment with its contents is stoppered with a rubber, whirled in a centrifuge for three minutes, and placed in a

water bath at 67° C. The height of the fat column is then read. The total solids of the cheese may be estimated by drying the cheese in the flask previous to adding the sulphuric acid.

The methods of determining fat in dry milk, cream, and milk are also described.

Concerning the measurement of diastase activity in plant extracts, C. O. APPLEMAN (*Abs. in Science, n. ser., 41 (1915), No. 1048, pp. 175, 176*).—"Several methods have been proposed for the measurement of the velocity of diastase activity in plant extracts. The procedure adopted by several investigators is based upon the determination of the amount of reducing sugar, usually calculated as maltose, produced by the action of a definite amount of extract upon an excess of soluble starch for a definite length of time at constant temperature. The Kjeldahl 'law of proportionality' is sometimes observed and sometimes ignored."

The general inapplicability of the method for plant extracts is very strikingly shown in the following, which refers to the diastase activity in glycerin extracts from cold-storage potatoes: The number of milligrams of sugar at 40° C. per hour per 100 gm. of potato pulp, calculated as maltose, was 17 mg. of total reducing sugar on March 28, and the total sugar was 3.6. On December 20 the former was 24.6 and the latter 3.7. On January 13 the amounts were 81.9 and 3.7, respectively.

"Calculated on the basis of increase in total reducing sugars or maltose in the extract after incubation with soluble starch, the tubers would show a very marked increase in diastase with storage, but when calculated on basis of increase in total sugar, the diastase activity remains practically constant. The amount of sucrose in the tubers increases with cold storage. It is extracted with the diastase and is inverted at the incubation temperature, according to the law of the mass action. Since nonreducing, hydrolyzable sugars are present in many plant tissues and are subject to wide variation in the same tissue, the above-described method in unmodified form is not reliable." See also a previous note (*E. S. R., 32, p. 129*).

Estimates of cholesterol in serum by gravimetric and colorimetric methods, P. G. WESTON (*Jour. Med. Research, 29 (1914), No. 3, pp. 457-464*).—This is a continuation of work previously published^a and consists of a comparative study of the gravimetric digitonin method with the author's colorimetric method. For the experiments pure cholesterol prepared from gall stones, human brains, and blood serum was used. Determinations were made of (1) pure cholesterol, (2) impure cholesterol extracted from serum, and (3) impure cholesterol extracted from serum plus a known quantity of pure cholesterol.

"Known quantities of pure cholesterol subjected to the same process as that employed in the extraction of cholesterol from serum yielded 99.44 per cent according to the colorimetric estimates and 108.56 per cent by weight. Serum to which 1 mg. of pure cholesterol had been added to each cubic centimeter yielded an excess of 1 mg. per cubic centimeter according to the colorimetric method and an excess of 1.3835 mg. by weight. In the 17 experiments in which a known quantity of cholesterol was estimated by both methods the results obtained by colorimetric estimation were uniformly more accurate than the results obtained by weight."

The use of the interferometer in agricultural investigations, H. KAPPEN (*Landw. Vers. Stat., 83 (1914), No. 5-6, pp. 385-396; abs. in Ztschr. Angew. Chem., 27 (1914), No. 37, Refractenteil, p. 298*).—This apparatus is employed for determining the refraction of fluids. It is said to be a decided improve-

^a *Jour. Med. Research, 26 (1912), No. 3, pp. 531-546.*

ment over the immersion refractometer, inasmuch as it will give more dependable results for very dilute solutions. From some of the results obtained with the apparatus it seems clear that it can be employed for the examination of milk, water-soluble constituents of soils, dissolved substances in river water, etc.

The burning quality of cigar wrapper, III, S. TIJMSTRA (*Bul. Deli. Proefstat. Medan, No. 3 (1914), pp. 30, figs. 2*).—The burning quality of the wrapper is defined as the ease with which the burning of the wrapper keeps pace with the burning of the filler without lagging behind the latter. The glowing test is not believed to be a theoretical or practical test for determining the burning quality of a tobacco. Burning quality and glowing quality are to a certain extent opposing properties. The extinction capacity of the tobacco leaf could be determined or in its stead the thickness of the leaf. The denser the leaf the greater will be its glowing property and the less its burning power.

In determining the burning power of the tobacco, 4 trapezium-shaped pieces cut out of the tobacco leaf are rolled loosely on bamboo twigs, with the upper side of the leaf facing outwards. The small "cigars" thus prepared, containing the bamboo, are placed 1 cm. deep into small glass tubes 14 cm. high and 4 mm. wide. The surface of the "cigar" protruding from the glass tube should be just 12 sq. cm. The bamboo twig is then carefully removed from the tobacco, and the latter is dried over sulphuric acid (specific gravity 1.3) until a constant moisture content is obtained. The glass tube holding the "cigar" is inserted into the hole of a small rubber stopper, which is then put into a glass tube, bent four times vertically, and connecting with a 5-liter aspirating bottle provided with a 1-meter siphon tube. The cigar is lighted and the water is allowed to run from the aspirator flask at the rate of 500 cc. per minute. The number of seconds required to burn a cigar represents the burning quality of the tobacco, the less time required for burning the tobacco the better being the quality of the tobacco.

The methods for estimating burning quality of tobacco previously proposed by the author,^a by Garner (*E. S. R.*, 18, p. 35), and by other workers are discussed at length.

Studies on fruit juices, H. C. GORE (*U. S. Dept. Agr. Bul. 241 (1915), pp. 19*).—"The studies described in this bulletin were made with a view of finding methods for the preparation of juices from such fruits as the strawberry, blackberry, pineapple, orange, and lemon. . . . The actual fruit used wherever practicable was that produced under typical conditions in localities where it is grown extensively."

It was found that ordinary methods of sterilizing fruit juices by heat could be applied successfully to only a limited number of the special fruits as black raspberry, blackberry, black currant, sour cherry, and peach. The strawberry, red raspberry, red currant, pineapple, and citrus fruit juices, and apple cider were found to lose in flavor when sterilized by heat. Special tests were made with the latter named fruits for the purpose of devising methods of storing by refrigeration or sterilization with carbon dioxide.

The general methods of preparing fruit juices are discussed as a preliminary to the discussion of the special methods.

"Satisfactory yields of juice were easily obtained from all of the fruits studied. Lemon and orange juices were best expressed by cutting each fruit into several pieces and then pressing, a method which could be successfully used

^a Meded. Deli-Proefstat. Medan, 5 (1910), No. 2, pp. 25-45, figs. 3; 6 (1911), No. 8, pp. 257-288, figs. 3.

in pressing pineapples, although the method of pressing the fruit without previous cutting is probably superior. It was found advisable to pass all of the other kinds of fruit pressed without heating through an apple grater to facilitate the outflow of the juice.

“Heating before pressing in the case of black raspberry, blackberry, red currant, black currant, and huckleberry juices resulted in larger yields of juice and the development of more color and a more distinctive flavor than were obtained from cold pressing. Strawberries, red raspberries, cherries, peaches, pineapples, lemons, and oranges were cold pressed.

“Heating the juices sufficiently to sterilize them did not affect injuriously the color of any of the fruit juices, though pineapple, lemon, and orange juices usually darkened somewhat if heated in the presence of dissolved oxygen or if exposed to atmospheric oxygen during the heat treatment.

“The distinctive flavor of the fresh fruit was greatly injured and the familiar cooked-strawberry taste appeared when strawberry juice was sterilized by heat. The fresh fruit flavor of orange juice was also distinctly injured when the juice was heated. Although all lost in the quality of freshness, heating did not seriously affect the flavor of other fruit juices, except in cases where the heat employed was excessive.

“The extent to which color and flavor were retained on keeping the juice after sterilization varied greatly in the juices from the various fruits. In strawberry juice the brilliant red color of the freshly sterilized juices in all cases faded greatly and further flavor losses occurred. Sterilization and subsequent keeping in carbon dioxide were not effective in securing color retention.

“Red currant juice very gradually lost in distinctive color and flavor on being kept at room temperature after sterilization, and keeping in carbon dioxide was not effective in securing either color or flavor retention. Cold storage at from 32 to 35° F. was found to be a very satisfactory means of controlling color and flavor changes.

“The distinctive colors and flavors of black currant, blackberry, and black raspberry juices were satisfactorily retained during prolonged periods at common storage. The flavor of blackberries was, however, distinctly less well retained than that of black currants or black raspberries, though it did not undergo a perceptible change during a storage period of six months.

“In the case of red raspberries the distinctive color and flavor were poorly retained, even on keeping the juice in carbon dioxide in cold storage at from 32 to 35°.

“When sterilized and subsequently kept in carbon dioxide the distinctive color of pineapple juice remained practically unchanged. When exposed to atmospheric oxygen at juice surfaces during and after sterilization marked darkening occurred. Change in color was also found to be greatly, though not wholly, retarded by keeping the juice in cold storage at from 32 to 35°. On keeping the juice at ordinary temperatures the distinctive pineapple flavor gradually lessened, though the juices remained recognizable as pineapple. By keeping in cold storage at from 32 to 35° F. flavor change was almost wholly prevented.

“The distinctive colors and flavors of peach and cherry juices were quite well retained while kept at room temperatures. Huckleberry juice, hot pressed, lost in flavor on keeping.

“Lemon juice darkened in color if sterilized and kept in the presence of atmospheric oxygen, though the color was satisfactorily retained when the juice was sterilized and kept in carbon dioxide or in vacuum. In all cases an off-flavor, designated as a ‘bottled lime-juice’ flavor, appeared in the lemon

juice after it had been kept for a time after sterilization, even though in cold storage at from 32 to 35°.

"Orange juice also underwent a marked darkening in color when kept at room temperatures after being sterilized. The color was fairly well retained when atmospheric oxygen was excluded by sterilizing the juice and subsequently keeping it in vacuum or in carbon dioxide, and the change in color was well controlled by keeping the juice at low temperatures. The flavor of sterilized orange juice, already slightly injured by the heating necessary for sterilization, underwent further changes when kept at room temperatures. It was found that by keeping the juice in cold storage at from 32 to 35° the flavor was well retained for long periods.

"The distinctive colors and flavors of all fruit juices kept in freezing storage at about -10° C. (14° F.) were found to remain practically unchanged during many months, except that a peculiar coagulation of much of the coloring matter appeared in the juice of the black raspberry. It was possible to concentrate fruit juices to sirups by freezing out the water as ice and centrifuging. Characteristic colors and flavors were well retained on concentrating.

"Infusorial earth greatly promotes the filtering of fruit juices, as it retards greatly the clogging of the filter."

When, what, and how to can and preserve fruits and vegetables in the home, G. W. CARVER (*Alabama Tuskegee Sta. Bul. 27 (1915), pp. 3-8*).—A description of home canning methods. The material is arranged in seasonal form. A section on drying fruits and vegetables is included.

METEOROLOGY.

The rainfall régime of the several States, B. C. WALLIS (*Mo. Weather Rev., 43 (1915), No. 4, pp. 176-178, fig. 1*).—In this article an attempt is made to group the States which have similar rainfall conditions on the basis of rainfall data used in the construction of equipluves presented in previous articles (*E. S. R., 32, p. 119*). The results are shown in the following map:

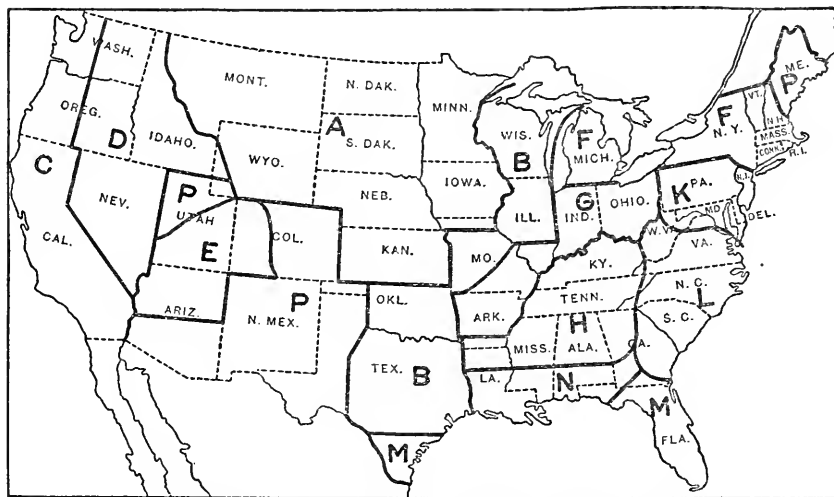

FIG. 1.—Approximate grouping of States as rainfall sections.

The rainfall regions shown on this map are as follows:

Summary of the rainfall régimes of the several States.

Sections (fig. 1).	Months bringing—		Average pre- cipitation.	Range of intensity.
	Principal maximum intensity.	Principal minimum intensity.

The distribution of the rainfall in the western United States, B. C. WALLIS (*Mo. Weather Rev.*, 43 (1915), No. 4, pp. 170-175, figs. 19).—This is a discussion similar to that of rainfall intensity of the eastern United States already noted (E. S. R., 33, p. 117). It contains twelve monthly maps of equipluvies besides charts of rainfall intensity, for the region west of the 103d meridian. These show "a notable regularity almost throughout the year, a very wet area gradually fades off into a very dry district. The exceptional month is October, when the raininess is uniformly below the average, and the elevated lands are wetter than the lowlands. The second general feature is the absence of very marked raininess or dryness on the mountains at any time of the year. This fact is well shown by the graphs for the mountain divisions. Consequently, in a broad way, the West contains three regions with three types of rainfall: (1) The far west, including the coast lands, with great rainfall intensity throughout the period November to March—i. e., winter rains; (2) the mountains, never very wet, never very dry; (3) the eastern slopes, with great rainfall intensity in the north from April to June, and in the south from July to September—i. e., summer rains."

A study of the rainfall charts for the western United States in conjunction with those of the eastern United States "indicates that the rainfall of the United States as a whole is determined by (1) continental influences which are exerted over a broad triangle of country, with the vertex to the south and with the edge of the Rocky Mountains as the eastern limb of the triangle; (2) oceanic influences exerted upon the coastal lowlands, (a) on the west from the Pacific and (b) on the east from the Atlantic; (3) intermediate regions (a) the Rockies in the west and (b) the western Appalachians on the east; and (4) direct solar influences which are manifest with some elements of variety along the southern boundary as far west as Yuma, Ariz."

The influence of a western yellow pine forest on the accumulation and melting of snow, A. J. JAENICKE and M. H. FOERSTER (*Mo. Weather Rev.*, 43 (1915), No. 3, pp. 115-126, pls. 3).—This article reports a study of the influence of a virgin western yellow-pine forest on the accumulation and melting of snow. This study was made at the Fort Valley (Forest) Experiment Station,

Ariz., during the winters of 1910-11 and 1912-13 "upon two areas, alike in all respects, except that one was forested and the other naturally treeless."

The results, reported in detail, indicate that there was no appreciable difference in the total amount or density but great difference in distribution on the ground of snow in the forested and nonforested areas. The rate of melting in winter was greater in the forest than in the open. Melting in spring was most rapid and the run-off greatest in the open. The snow disappeared more gradually and the absorption and retention of water by the soil was greater in the forest than in the open.

The authors conclude in general "that the value of forest cover in the conservation of snow waters is great, even when that forest cover is of such an open and broken character as the typical western yellow-pine forest on which observations were made in this study." Commenting upon this study and the deductions drawn from it, officials of the Weather Bureau question whether certain of the conclusions drawn, especially those relating to the causes of difference in conservation of snow in the forested and open areas, are sufficiently supported by the data presented.

Atmospheric influence on evaporation and its direct measurement, B. E. LIVINGSTON (*Mo. Weather Rev.*, 43 (1915), No. 3, pp. 126-131, figs. 2).—This article deals briefly with some general principles of atmometry and discusses the relative merits of different types of atmometers, especially the porous clay-cup atmometer. It is stated that the latter "possesses all the advantages over the free water surface that are possessed by the Piche, Piche-Cantoni, and Bellani instruments. Its main advantage over these instruments lies in this, that its surface projects up into the air and is exposed equally to wind action in all directions. Its surface is somewhat similar to that of plants, which is also the surface of a water-imbibed solid, and its exposure to the surrounding aerial conditions is similar to the mean exposure of the surfaces of the foliage of an entire plant. For this reason it has proved especially valuable in studies bearing upon water loss from plants. The rigidity of the cups also makes them more satisfactory than the somewhat flexible paper disks."

A bibliography of literature relating to the subject is appended.

Monthly weather periodicity, V. KÖPPEN (*Mo. Weather Rev.*, 43 (1915), No. 4, pp. 179-181).—This article adduces evidence to show that there is no weather periodicity due to the influence of the moon.

Influence of the moon on weather (*Mo. Weather Rev.*, 43 (1915), No. 4, p. 182).—A brief reference is here made to a memoir by G. Wagner which contains a critical summary of modern scientific investigations on the possible lunar influences on terrestrial weather. This refutes the popular belief that this influence is sufficiently strong to permit of its direct unaided observation, and that one can even deduce weather forecasts from it.

Monthly Weather Review (*Mo. Weather Rev.*, 43 (1915), Nos. 3, pp. 99-157, pls. 11, figs. 6; 4, pp. 159-209, pls. 8, figs. 27).—In addition to weather forecasts, river and flood observations, and seismological reports for March and April, 1915; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; a condensed climatological summary; and the usual climatological tables and charts, these numbers contain the following articles:

No. 3.—The Total Radiation Received on a Horizontal Surface from the Sun and Sky at Washington, D. C. (illus.), by H. H. Kimball; Solar Radiation Intensities during January, February, and March, 1915, and the Total Solar and Sky Radiation during March at Washington, D. C., by H. H. Kimball; Thermo-isopleths for Washington, D. C. (illus.), by C. Abbe, jr.; The Influence of a Western Yellow Pine Forest on the Accumulation and Melting of Snow (illus.),

by A. J. Jaenicke and M. H. Foerster (see p. 319); Atmospheric Influence on Evaporation and Its Direct Measurement (illus.), by B. E. Livingston (see p. 320); The Introduction of Meteorology into the Courses of Instruction in Mathematics and Physics, by C. Abbe; Lightning and Protection from It, by J. Larmor; Lightning Injury to Cotton and Potato Plants, by L. R. Jones and W. W. Gilbert; Weather and Health; and Huntington on the Climatic Factor, by W. J. Humphreys.

No. 4.—Solar and Sky Radiation Measured at Washington, D. C., during April, 1915, by H. H. Kimball; The Origin of the Wind (illus.), by J. W. Sandström; Some Recent Researches on the Motion of Fluids (illus.), by H. Batesman; The Distribution of the Rainfall in the Western United States (illus.), by B. C. Wallis (see p. 319); The Rainfall Régime of the Several States (illus.), by B. C. Wallis (see p. 318); Meteorological Observations Near Schiefflin, Liberia, 1913–1914, by P. C. Day; Monthly Weather Periodicity, by V. Köppen; Influence of the Moon on Weather; and Beaufort Wind Scale and New Russian Equivalents, by B. Galitzin.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data, 1 (1914), No. 13, pp. 386, pls. 2, figs. 44*).—This number contains brief summaries and detailed tabular statements of climatological data for each State for the year 1914.

Climatological data for the United States by sections (*U. S. Dept. Agr., Weather Bur. Climat. Data, 2 (1915), Nos. 3, pp. 234, pls. 2, figs. 7; 4, pp. 226, pls. 2, figs. 12*).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for March and April, 1915, respectively.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER, R. E. McLAIN, and D. POTTER (*Massachusetts Sta. Mct. Buls. 317, 318 (1915), pp. 4 each*).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during May and June, 1915, are presented. The data are briefly discussed in general notes on the weather of each month.

SOILS—FERTILIZERS.

[Soil analyses], A. N. HUME (*South Dakota Sta. Rpt. 1913, pp. 19–24*).—Incomplete chemical analyses of the brown sandy loam soil used in fertility experiments previously noted (*E. S. R., 29, p. 728*) indicate that the average nitrogen content of the surface soil to a depth of 6 $\frac{3}{4}$ in. over an acre weighing about 2,000,000 lbs. is 6,325 lbs. The acid-soluble phosphorus in the same amount of soil averages 1,151 lbs., and the incomplete analyses for potassium indicate a content of 23,720 lbs. The results as a whole are taken to indicate that phosphorus is the limiting element in this soil.

Gola's osmotic theory of edaphism, F. CAVERS (*Jour. Ecology, 2 (1914), No. 4, pp. 209–231*).—It is the object of this article to summarize a series of contributions to edaphology by G. Gola.

Colloidal phenomena, with special reference to soil colloids, are first briefly considered as forming an essential part of the basis of Gola's theory. Gola's main thesis is "that the relations between plants and the soil are chiefly determined by the concentration of the soil solution and the limits between which this may vary, and he lays special stress upon the contrasting characters of the colloidal and crystalloidal constituents of the soil. . . ."

"Soils may be divided into two main groups—(1) soils in which the soil solution is rich in mineral substances and its concentration is relatively high, though

liable to vary within somewhat wide limits, and (2) soils in which the soil solution is poor in mineral substances and shows a relatively low and usually also a relatively constant concentration. The roots or other absorbing organs in contact with a soil solution of the first type are subject to high osmotic pressure, which is moreover very variable, so that the plant must use such means of regulation as it possesses in order to guard against the differences in tonicity of the solution around its absorbing surface. In plants growing in a soil solution of the second type the osmotic pressure around the absorbing surface is very low, and its relative constancy enables the plant to dispense with the regulatory mechanisms necessary for those growing in a more concentrated solution."

A list of Gola's papers bearing on the subject is appended.

The nature and methods of extraction of the soil solution, W. STILES and I. JØRGENSEN (*Jour. Ecology*, 2 (1914), No. 4, pp. 245-250).—Results obtained by different experimenters using different methods in investigating the actual nutrient medium of plants by isolating and analyzing the soil solution are briefly reviewed.

It is thought that the investigation of the composition of soil water marks a great advance in soil investigations. "However, the complex character of the soil must not be forgotten, and it is especially necessary to remember that the presence of colloidal substances (hydrosols and hydrogels) will naturally alter the conditions of things."

It is also thought that in extracting the soil solution the relations between the crystalloids and colloids of the soil will suffer disturbance which will result in a corresponding difference between the actual soil solution and that obtained by extraction. It is concluded, therefore, that the advance along such lines "must depend very largely on further investigations into soil physics."

A list of references to related literature is appended.

The difficulty with which soils and finely pulverized substances generally are moistened, P. EHRENBURG and K. SCHULTZE (*Kolloid Ztschr.*, 15 (1914), No. 5, pp. 183-192, fig. 1).—The authors briefly review the work of others bearing on the subject, and report experiments with pulverized peat and lampblack, from the results of which they conclude that the difficulty of moistening lampblack, peat, and soil in the pulverized condition is due to the adsorption of air and not to waxy or resinous coverings on the particles.

The ground water, E. GROHMANN (*Jour. Landw.*, 62 (1914), No. 2, pp. 121-123, figs. 2).—This article deals with the relations between precipitation, water level in rivers, and ground-water level, with particular reference to the Elbe River district in the neighborhood of Dresden.

The results of several years' observations in this district show a marked influence of the precipitation on the ground-water level, which is, however, less marked with the heaviest and the lightest rainfall in a given time than with the rainfall of medium intensity, and less the lower the atmospheric humidity.

The low ground-water level and Elbe River level in the district during the past ten years, in spite of the heavy precipitations, is attributed to smaller water absorbing and retaining powers of the soil caused by the kind of cultivation practiced.

Water movement in peat, H. J. FRANKLIN (*Massachusetts Sta. Bul.* 160 (1915), pp. 113-115).—Observations made, by means of test holes, on the movement of water in the peat soil of the cranberry bog at the substation at Wareham, Mass., indicated that if conditions in this bog are representative, the horizontal movement of water through the peat of cranberry bogs is very rapid.

Antagonism between anions as affecting barley yields on a clay adobe soil, C. B. LIPMAN and W. F. GERICKE (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 201-218, pl. 1).—Pot culture experiments with barley on a clay adobe soil mixed with sodium chlorid, sodium sulphate, and sodium carbonate, singly and in different combinations, are reported, the results of which establish for the first time, in the author's opinion, the existence of antagonism between anions for barley in a clay adobe soil. Two crops were grown in succession in the same pots, allowing the soil a rest period of three months.

Antagonism was shown between sodium chlorid and sodium sulphate and between sodium chlorid and sodium carbonate in the second crop. None was shown in the first crop. There was slight antagonism between sodium carbonate and sodium sulphate in the first crop but it is considered questionable whether any existed at all in the second crop.

In testing the toxicity of single salts, it was found that 0.1 per cent each of sodium chlorid and sodium sulphate stimulated barley in the first crop and was toxic in the second crop. Sodium carbonate did not manifest toxicity, but on the contrary showed stimulation even up to concentrations equal to 0.3 per cent of the dry weight of the soil.

In an experiment similar to these, in which sodium sulphate was used in constant toxic quantities of 0.4 per cent and calcium sulphate in varying quantities, it was found that the calcium sulphate strongly antagonized the sodium sulphate in both the first and second crops. "At least so far as some seasons are concerned, small quantities of gypsum are as efficient for the purpose as larger quantities, if not more so. . . ."

"It would appear from the above results that it would not be a difficult matter to establish a mode of treatment which would involve the neutralization of the toxic effects of any one or even two of the alkali salts by another alkali salt. . . . It is clear that in a heavy soil, at least by additions of gypsum at the rate of about 2 tons to the acre or common salt in smaller quantity, we could change the soil from a very poor into a normally producing one, despite the fact that we have very considerably increased the total salt content thereof."

A list of references to literature bearing on the subject is appended.

Antagonism between anions as affecting soil bacteria.—III, Nitrogen fixation, C. B. LIPMAN and P. S. BURGESS (*Centbl. Bakt. [etc.]*, 2. Abt., 42 (1914), No. 17-18, pp. 502-509).—In further studies of the effects of alkali salts on bacteria in soils (*E. S. R.*, 32, p. 320), nitrogen fixation investigations were conducted from which the following conclusions are drawn:

"Very slight, perhaps questionable antagonism between anions occurs for the nitrogen fixing flora of . . . sandy soil when Na_2CO_3 and NaCl are mixed, whether one or the other is used as a constant toxic factor. The same is true when NaCl and Na_2SO_4 are combined, provided the first-named salt is the constant toxic factor. It is not true when Na_2SO_4 is used as the constant toxic factor. No antagonism obtains between Na_2CO_3 and Na_2SO_4 no matter how the salts are combined and no matter which of them is used as the constant toxic factor. The concentrations at which nitrogen fixation ceases are lower when the salts are mixed than when they are used singly.

"The nitrogen fixing flora differ totally in respect to antagonism between anions from the ammonifying and the nitrifying flora of the same soil. The resistance of these nitrogen-fixing flora, however, to salt effects is far greater than that of the other flora named."

Relation of carbon bisulphid to soil organisms and plant growth (*Wisconsin Sta. Bul.* 250 (1915), pp. 18, 19).—It was found in experiments by E. B. Fred that the effect of carbon bisulphid on plant growth is not a constant factor,

but varies with the type of soil employed, a marked harmful effect being produced with acid soils. The most consistent beneficial results were obtained with plants demanding a large amount of sulphur.

New experiments on alkali soil treatment, C. B. LIPMAN and L. T. SHARP (*Univ. Cal. Pubs. Agr. Sci.*, 1 (1915), No. 9, pp. 275-290, pls. 4).—Experiments on the treatment of alkali soils are reported which were based on the principle of antagonism between ions and between anions discussed in the two reports noted above, and on the behavior of soil colloids and chemical soil constituents in the presence of soluble salts.

The soil used contained 0.64 per cent of water-soluble salts, 0.459 per cent being sodium chlorid, 0.068 per cent sodium sulphate, and 0.083 per cent sodium carbonate. It had never been cropped and had borne only a sparse vegetation of plants resistant to alkali and drought. The different pots containing 6 kg. of the soil received the following treatments: 30.42, 41.76, and 11.02 grains of sulphuric acid, 62.08 grains of calcium sulphate, 6 grains of copper sulphate, 30 grains of ferrous sulphate, 12 grains of sodium sulphate, and 300 grains of air-dry barnyard manure. Three days after treatment the pots were planted to barley.

It was found that the sulphuric acid treatments were especially beneficial, particularly at the smallest application, to the growth of barley. The treatments with calcium and ferrous sulphates and barnyard manure were also instrumental in improving very materially the producing power of the soil for barley. Copper and sodium sulphates had no favorable effect on the yield of barley and appeared to render the soil a poorer medium for its growth. With reference to the total yields of grain produced, the smallest of the three sulphuric acid applications gave by far the best results of all the treatments. Gypsum stood second in this respect, while the intermediate sulphuric acid treatment and the manure treatment gave about the same results. The root development was most constant and regular in the sulphuric acid pots.

In explanation of the causes underlying these results "it may be said . . . that the H_2SO_4 exerted its influence both in the direction of neutralizing the Na_2CO_3 and that of improving the soil's physical condition through its shrinkage of colloids. In smaller measure gypsum exerted similar effects and in addition thereto exerted the characteristically strong antagonistic effect to the sodium and acid ions which calcium is known to exert in the plant world. The effects of $FeSO_4$ are to be explained in general as are those of $CaSO_4$. The effect of the barnyard manure is probably exerted through the organic colloids produced in its decomposition, which through the enormous surface they possess hold much of the salts or components of the latter in a condition which prevents their ready solution in the soil water."

A brief outline of further studies along this line, which are to be reported later, is given.

The dead moor on Steinhude Lake, C. BIRK (*Arb. Lab. Tech. Moorverwert.*, 1 (1914), No. 1, pp. 1-102, pls. 12, figs. 5).—This paper describes the geography, geology, and climate of the district in Schaumburg-Lippe in which the dead moor occurs, and reports studies of the origin and development of the moor and of the chemical and physical properties of the different kinds of peat, with particular reference to their industrial uses. The new sphagnum peat is the predominating type.

It is stated that the industrial utilization of the peat must precede the successful agricultural development of this moor. Analyses of samples of the moor soil taken at two depths (the layer to a depth of about 8 in. and the layer from 8 in. to about 40 in.) indicate that the upper layer contains about 0.7 per

cent nitrogen, 2.4 per cent mineral matter, 0.19 per cent lime, and 0.04 per cent phosphoric acid, while the lower layer contains about 0.9 per cent nitrogen, 1.97 per cent mineral matter, 0.29 per cent lime, and 0.05 per cent phosphoric acid.

The surface soil is somewhat lower in plant food content than the average northwest German high moor soil, but it is thought that with proper cultural treatment it is fit for farming purposes.

Management of marsh soils (*Wisconsin Sta. Bul. 250 (1915), pp. 12-14*).—Cooperative tests reported by H. ULLSPERGER demonstrate the importance of the use of commercial fertilizers containing potassium and phosphorus on marsh soils.

The results of technical moor utilization, G. KEPPELER (*Arb. Lab. Tech. Moortverwert.*, 1 (1914), No. 1, pp. III-XIII).—The author briefly discusses the agricultural development of peat moors and the use of peat for fuel and for the manufacture of illuminating gas and ammonia.

Changes in a sterile sand by cropping, E. BLANCK (*Jour. Landw.*, 62 (1914), No. 2, pp. 129-140).—In continuation of work along the same general lines (E. S. R., 31, p. 621), three years' pot experiments were conducted with oats and peas, using a sterile quartz sand from the Oder River to determine the extent to which the plant food in the sand is set free by the roots of the plants.

It was found that the small stock of plant food in the sand was readily yielded to plants and the sand rapidly impoverished in plant food, being by the fourth year without fertilization completely unfit for plant growth. The impoverishment in plant food, especially lime and magnesia, due to culture of peas was much more marked than that due to culture of oats, thus verifying the theory that leguminous plants possess greater power for setting free plant food than gramineous plants. The peas as a first crop favorably influenced the oats as a second crop, due to the great power of the former for setting free plant food. The reverse was not true.

It was also found that in cases of potash deficiency sodium was effective as a substitute.

Management of sandy soils (*Wisconsin Sta. Bul. 250 (1915), pp. 8-11, figs. 3*).—In a description of experiments by H. ULLSPERGER on the management of sandy soils it is stated that the incorporation of humus in the soil by a system of plowing under the second crop of clover has for two years greatly increased the water-holding capacity of the soil. It is believed that the use of commercial fertilizers in combination with green manuring crops will permit the profitable working of sandy soils when crops adapted to such soils are grown.

Farm manures, J. C. BEAVERS (*Indiana Sta. Circ. 49 (1915), pp. 20, figs. 3*).—“This publication is prepared for the purpose of acquainting farmers with the value and the best methods of conserving and using farm manures.”

Farm manure, G. A. OLSON (*Washington Sta. Popular Bul. 90 (1915), pp. 8*).—This gives a popular discussion of the value of farm manure, methods of preserving it, and its proper application, with particular reference to farming conditions in the State of Washington.

Data from various sources are reviewed to show the favorable effects of using manure in the State, particularly when consisting of a mixture of solid and liquid manure.

Chemical preservation of manure, P. A. MAIGNEN (*Abs. in Science, n. scr.*, 41 (1915), No. 1054, p. 405).—This is a brief note on a paper presented at the recent Philadelphia meeting of the American Association for the Advancement of Science, in which a plea was made for the better conservation of the valuable fertilizing matter which is now largely going to waste as sewage.

Manuring of farm crops (*Armstrong Col., Newcastle-upon-Tyne, Agr. Dept. Bul. 11, pp. 8*).—Directions based upon field experiments at Cockle Park and elsewhere in the northern counties of England for the use of manures and commercial fertilizers on various crops, including rutabagas (swedes), turnips, potatoes, mangels, cabbages, barley, oats, wheat, beans, and grass and clover mixtures, are given. The directions take account of the shortage in supply of potash salts and restrict, or entirely eliminate, the use of potash.

Influence of organic substances on the decomposition and action of nitrogenous compounds in the soil, GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1915), No. 5, pp. 309-327*).—Pot experiments on this subject have already been noted (*E. S. R., 27, p. 626*).

The experiments here reported were made with pits each containing 1 cubic meter of soil. Otherwise the method of investigation was substantially the same as in the pot experiments, and the results were in the main the same. The organic matter was applied in the form of ground straw used in varying amounts alone and in combination with sodium nitrate.

The results were inconclusive as to the value of the straw alone for increasing the productiveness of the soil. They were, however, conclusive as regards the effect of such substances in reducing the assimilation of nitrate nitrogen. When the nitrate nitrogen was used alone 60 per cent of the amount applied was recovered in the crop. When it was applied in combination with straw only 20 per cent was recovered in the crop.

Conditions of Chilean nitrate industry, V. L. HAVENS (*U. S. Dept. Com., Com. Rpts., No. 73 (1915), p. 1249*).—The conditions as regards production, plants in operation, wages, freight rates, and prices up to and including January, 1915, are briefly summarized.

The fixation of atmospheric nitrogen, W. S. LANDIS (*Metallurg. and Chem. Engin., 13 (1915), No. 4, pp. 213-220, figs. 17; Jour. Indus. and Engin. Chem., 7 (1915), No. 5, pp. 433-438, figs. 3; abs. in Amer. Jour. Sci., 4, ser., 39 (1915), No. 234, pp. 676, 677*).—This article deals particularly with the cyanamid process and the factory established at Niagara Falls to manufacture nitrogen compounds by this process.

Fixation of atmospheric nitrogen, L. L. SUMMERS (*Amer. Fert., 42 (1915), No. 6, pp. 41-52*).—The various processes of fixation of atmospheric nitrogen which have shown promise of practical success are described and their commercial possibilities are discussed.

Is the loss of lime from the soil increased by kainit fertilizing? GERLACH and VECKENSTEDT (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1915), No. 5, pp. 382-388*).—The results of pot experiments here reported show that fertilizing with kainit caused a marked increase in the loss of lime in the drainage water. This loss was greater with kainit than with other fertilizing materials. There was, however, a considerable loss of nitrogen from unfertilized soils. It was also observed that the loss was much greater in very loose soil than in soil in natural condition. An examination of 120 different soils showed that the lime content of the subsoil was uniformly greater than that of the surface soil.

Manuring experiments with manganese carbonate in Italy, G. D'IPPOLITO (*Agr. Mod. [Milan], 20 (1914), No. 17, pp. 259, 260; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 11, pp. 1424, 1425*).—A marked increase in yield of wheat and alfalfa from applications of 180 lbs. per acre of a natural manganese carbonate (35 per cent carbonate) and of a natural phosphocarbonate (containing 35 per cent carbonate and 11 per cent phosphoric acid) is reported.

Wool and leather wastes, E. J. RUSSELL (*Jour. Bd. Agr. [London]*, 21 (1915), No. 12, pp. 1087-1092).—The fertilizing value of shoddy as indicated by analysis and by the results of field experiments is briefly discussed. A note is also given on the fertilizing value of leather waste, emphasizing particularly the necessity of treating the leather with sulphuric acid to make it more available as a fertilizer.

A note on the export of manures from India (*India Tea Assoc., Sci. Dept. Quart. Jour.*, No. 2 (1914), pp. 49-51).—Data for the years 1910-11, 1911-12, and 1912-13 for exports of bones, fish manure and guano, oil cake, and other fertilizing materials are tabulated.

A pronounced increase in exports of all kinds of fertilizing materials occurred during the period named. The increase was especially marked in the case of oil cake. The figures for 1912-13 are as follows: Bones, 110,221 long tons, valued at \$2,558,245.97; fish manure and guano, 21,408 tons, valued at \$337,768.52; oil cake, 3,235,703 tons, valued at \$3,996,869.14; and other fertilizing materials, 8,338 tons, valued at \$247,630.74. The largest importers of bones were, in the order named, Belgium, France, the United Kingdom, Germany, Japan, and Ceylon: the United States imported 7,761 tons. The larger proportion (17,885 tons) of the fish manure went to Ceylon. Of the oil cake the largest importers were, in the order named, Ceylon, United Kingdom, Japan, and Germany. The use of fertilizers in Ceylon, especially in tea culture, is comparatively large and steadily increasing.

AGRICULTURAL BOTANY.

Inorganic plant poisons and stimulants, WINIFRED E. BRECHLEY (*Cambridge: University Press, 1914, pp. X+110, pls. 7, figs. 12*).—The author gives an account of investigations on the toxic effect of compounds of copper, zinc, arsenic, boron, and manganese on different species of plants.

Summarizing the results obtained, she states that copper compounds act as poisons to higher plants, and that only under particular and peculiar conditions and in very great dilutions is any stimulative action clearly demonstrated.

Zinc compounds are somewhat less toxic to higher plants, and their stimulating influence is still considered uncertain except in very great dilutions. In soil cultures increased growth seems to have been established, as certain species of plants respond to zinc salts, though no increase is obtained with other species. Among the fungi, particularly with *Aspergillus niger*, the stimulating effect is recognized.

The toxic effect of arsenic upon higher plants was found much more marked with arsenious acid and its compounds than with arsenic acid and its derivatives. With certain algae stimulation may follow the presence of arsenic compounds under certain conditions, while with fungi it appears that some species are able to live in the presence of arsenical compounds.

Among the boron compounds boric acid is said to be less harmful than are the compounds of copper, zinc, and arsenic. There seems to be evidence that below a certain limit of concentration boron exercises a favorable influence upon plant growth, encouraging the formation of stronger roots and shoots. Fungi appear to be very indifferent to boron, and there is said to be evidence to show that certain green algae can withstand large quantities of it.

Manganese exerts a toxic influence on the higher plants if present in high concentration, but in the absence of an excess of manganese compounds the poisoning effect is overshadowed by a definite stimulation. It is considered probable that manganese may prove to be an element essential to the economy of plant life, even though the quantity usually found in plants is very small.

In conclusion the author takes exception to the hypothesis that all inorganic plant poisons act as stimulants when they are present in very small quantities. She thinks a more accurate statement would be that some inorganic poisons act as stimulants when in small amounts, the stimulating concentrations varying with the poisons used and the plants on which they act.

A bibliography is appended.

Toxic effect of iron and aluminum salts on clover seedlings, R. W. RUPRECHT (*Massachusetts Sta. Bul.* 161 (1915), pp. 125-129, pl. 1).—The author claims that either iron or aluminum sulphate is harmful to the roots of clover plants, even in dilute solutions. This toxicity is overcome in large measure by the use of calcium carbonate up to a certain point, beyond which it is ineffective. Calcium sulphate does not have this beneficial effect, which would seem to indicate that it is the combination involved, and not the mere presence of the calcium, which is here effective.

Calcium carbonate counteracts iron and aluminum by precipitating them as hydroxids. The toxic action of the higher concentrations of iron and aluminum, despite the excess of calcium carbonate present, is thought to be due to the solubility of the iron hydroxid.

The idea that the toxicity of iron and aluminum salts is due to the penetration of the salts into the seedlings does not seem to be borne out. Evidence is offered in favor of the view that the toxic action is limited to the first layer or two of the cells in the growing portion of the root. The final death of the seedlings is due to a lack of nourishment rather than to a poisoning of the seedling itself. No appreciable increase in iron content is found in roots or tops of clover plants showing poor growth attributed to the influence of iron.

Effect of salicylic aldehyde on plants in soil and solution cultures, J. J. SKINNER (*Biochem. Bul.*, 3 (1914), No. 11-12, pp. 390-402, pls. 2).—On account of the reported presence of salicylic aldehyde in agricultural soils (*E. S. R.*, 28, p. 418), the author has conducted experiments with various plants in solution cultures and in soil in pots. In addition the action of this substance, it is said, is being tested with various crops in the field.

Wheat, corn, cowpeas, cabbage, and rice have been tested in solution cultures, and wheat, corn, clover in soil cultures, and it was found that salicylic aldehyde was harmful to wheat and rice seedlings in distilled water, and to all the crops tested in nutrient solutions and in soil in pots. The effect of solution cultures with various fertilizer ingredients was also tested with wheat, and it was found that in amounts as small as 10 parts per million, salicylic aldehyde was injurious to its growth. The effect of this substance on the absorption of nutrient salts indicated that there was a more nearly normal absorption of phosphate than of nitrate or potash under the influence of salicylic aldehyde. In the presence of calcium carbonate the injurious influence was somewhat ameliorated. Experiments show that under alkaline conditions the harmfulness of salicylic aldehyde can not be attributed to any slight acidity it may possess.

On the decrease of permeability due to certain bivalent cations, W. J. V. OSTERHOUT (*Bot. Gaz.*, 59 (1915), No. 4, pp. 317-330, figs. 11).—It is stated that while sodium chlorid and other salts of monovalent metals increase the permeability of protoplasm, calcium chlorid has the opposite effect. This effect, however, is not permanent. If exposure is sufficiently prolonged, it will be found that it gradually passes away and is followed by increase of permeability. The question of the behavior of other bivalent cations has arisen, and the author investigated the action of a number of them on living tissues of *Laminaria saccharina*.

It was found that there was a remarkable difference between monovalent and bivalent cations in their effects on permeability. While none of the monovalent cations, except hydrogen, are able to decrease permeability, all of the bivalent cations so far investigated (Mg, Ca, Ba, Sr, Mn, Co, Fe, Ni, Zn, Cd, Sn) are able to do so to a marked degree.

The production of anthocyanins and anthocyanidins, II, A. E. EVEREST (*Proc. Roy. Soc. [London], Ser. B, 88 (1914), No. B 603, pp. 326-332*).—In a previous paper (E. S. R., 31, p. 626) the author showed that the red pigments obtained as the result of careful reduction of the yellow flavonol derivatives are identical with the natural anthocyanins of plants. This point having been controverted, he has repeated some of his investigations and shows that by the reduction of flavonol glucosids, the yellow pigments present in many flowers, a series of red pigments may be obtained whose properties agree with those of the anthocyanins.

Apart from the question of anthocyan the author reports that where he obtained an anthocyan by reduction of the flavone or flavonol present in the flower extracts, he was able to show that the pigment was an anthocyanin. It would therefore follow that in each case the flavone or flavonol derivative in the plant must have been present in the form of a glucosid.

A comparative study of oxidation by catalysts of organic and inorganic origin, A. J. EWART (*Proc. Roy. Soc. [London], Ser. B, 88 (1914), No. B 603, pp. 284-320*).—This paper is a report of investigations carried out on the influence of poisoning on apples and potatoes, and in the author's judgment it necessitates a general revision of the oxidase ferments, in particular a general comparison with metallic oxidases. Detailed studies are given of apple and potato oxidase, and a comparison is made with inorganic catalysts, as well as oxidases from a number of different species of plants.

The author claims there is no justification for the use of such terms as peroxidase, catalase, etc., to indicate specific substances, ferments, or groups of ferments. It is, however, permissible to use such terms as catalase action or peroxidase action. Comparison with metallic oxidases shows that there is at present no reason for assuming the existence of specifically distinct plant oxidases.

Cytological studies of *Azotobacter chroococcum*, A. BONAZZI (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 3, pp. 225-241, pls. 3*).—From these studies as described, the author concludes that the cells of *A. chroococcum* present a complex nature and different stadia of cytological make-up. The organism shows peculiar granulations apparently not related to reproduction. These take the basic dyes and are constituted neither of fats nor glycogen, starch nor chromatin, but appear to be of a metachromatic nature. They seem to have their genesis from the nucleus. Their disposition in the cells is not constant, but changes in different individuals. Their regular appearance in the cells of *A. chroococcum* might be caused by the special conditions of life.

A bibliography is given.

Physiological studies of *Bacillus radicola* of Canada field pea, M. J. PRUCHA (*New York Cornell Sta. Mem. 5 (1915), pp. 83*).—In view of the fact that the results of inoculating legumes with pure cultures have not always proved satisfactory, the author has carried out extensive investigations involving the isolation and identification of the organism causing nodule development on the roots of the Canada field pea, a study of the influence of various factors on nodule development on the plant when in water or soil cultures, and a study of the influence of various environmental conditions on the infecting power of the organism. It is stated that the causal organism is *B. radicola*.

Nodules developed readily and continuously in light, but still more in darkness, also readily in soil extract and in synthetic nutrient solutions in which nitrates were either omitted or replaced by chlorids, but in a full nutrient solution containing nitrates continual development seems to be inhibited soon after inoculation. No nodule development takes place in nutrient solutions in which the individual essential elements are omitted, except in the case of nitrogen. In sandy soil the optimum moisture content was from 20 to 40 per cent. The addition to sandy soil of small percentages of peptone or of KNO_3 , $\text{Ca}(\text{NO}_3)_2$, NH_4Cl , FeCl_3 , or KCl inhibited nodule development, while the addition of tannic acid or of MgSO_4 , KH_2PO_4 , or $\text{Ca}(\text{H}_2\text{PO}_4)_2$ showed a beneficial effect.

Nutrition markedly influences the morphology of the nodule organisms. The effects are described of several media and modifications thereof, as employed. The infecting power of *B. radicicola* on field pea was not affected after 2½ years on a given medium in the laboratory, the culture being transferred each month. It was not appreciably influenced by nitrogenous or other media, all living cultures producing nodules. In some media and under certain conditions the organisms died sooner than in other media. Detection of infecting power is comparatively easy, but accurate comparative measurement thereof is not yet possible.

A bibliography is given.

Negative heliotropism of the urediniospore germ tubes of *Puccinia rhamni*. F. D. FROMME (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 407, 408).—The author reports that when germinating urediniospores of *P. rhamni* were exposed to a unilateral diffused illumination during four or five hours, more than 80 per cent of the germ tubes grew away from the direction of the light. These negative heliotropic reactions are thought possibly to play an important part in bringing about the stomatal entrance of the germ tube.

Flora of Vermont (*Vermont Sta. Bul. 187* (1915), pp. 139–258).—This consists of a list, prepared by a committee of the Vermont Botanical Club, of the ferns and seed plants found growing within the State without cultivation.

FIELD CROPS.

Field experiments, 1914 (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 15 (1915), No. 2, pp. 247–317).—Results of variety tests with barley, potatoes, mangels, oats, turnips, and wheat are reported.

As a result of several years experiments in fertilizing meadow hay, it is noted that applications of 10 tons of barnyard manure per acre gave satisfactory results, but good returns were also obtained from the use of 100 lbs. of nitrate of soda, 200 lbs. superphosphate, and 200 lbs. kainit per acre. The superphosphate and kainit were applied together before the end of February and the nitrate at the end of March or early April. The application of kainit in the fall often gave better yields, but not sufficient to warrant the cost of the separate application. Basic slag is noted as giving better results in a wet season than in a dry. Liquid manure was found to give excellent results with all hay crops in both wet and dry seasons. The standard mixture of fertilizer above mentioned is also recommended for peat soils.

With potatoes, the best results were obtained by the use of 100 lbs. sulphate of ammonia, 400 lbs. superphosphate, and 100 lbs. muriate of potash in the row in connection with a moderate use of barnyard manure. It is noted that manurial experiments with potatoes on peat soils are in progress.

Experiments in the use of seaweed at the rate of 15 tons per acre as a fertilizer for potatoes showed that "weight for weight, seaweed seldom produces

as heavy a crop of potatoes as does farmyard manure; muriate of potash generally has less effect when used with seaweed than when applied with dung; seaweed gives the best results on light soils and possibly in a dry season."

The advantage of allowing potatoes to sprout before planting was shown in increased yields of approximately 2 tons per acre. Experiments to note the effect of change of seed potatoes are noted as in progress.

With mangels the most satisfactory results were obtained by the use of 400 lbs. superphosphate, 200 lbs. sulphate of ammonia, and 400 lbs. salt. In manurial tests with oats the application of sulphate of ammonia alone and superphosphate alone gave results which, while variable, proved on the whole to be profitable. The two applied together were more satisfactory. A complete fertilizer gave the best results.

The following conclusions are given as results of manurial tests with turnips: "Though good crops of turnips may be grown with farmyard manure alone, it is not economical to apply heavy dressings. A medium dressing of farmyard manure, say, from 10 to 15 tons per statute acre, supplemented by superphosphate or basic slag, is better than a heavy dressing of dung alone.

"Of the three kinds of artificial manures, nitrogenous, phosphatic, and potassic, phosphatic manures alone materially increased the yield. When a medium dressing of dung supplemented by superphosphate or basic slag is used, it is very doubtful whether the addition of either sulphate of ammonia or kainit, or both, will pay. But when no dung is used it is advisable to apply these manures along with superphosphate or basic slag. The use of a complete mixture has one decided advantage, inasmuch as a more even braird is obtained, the plants are stimulated in their early growth, and consequently suffer less injury from attacks of the turnip fly.

"Superphosphate and basic slag are practically of equal value as manures for turnips. The question as to which should be used to supplement dung must be decided by local circumstances, but where the land is deficient in lime or where the disease finger and toe is prevalent, basic slag should undoubtedly be applied. As much as 6 cwt. per statute acre of either manure may be used with satisfactory results. Especially is this the case when no farmyard manure is applied.

"Under ordinary conditions the following manurial dressings may be thoroughly relied upon to give satisfactory results: A medium dressing, from 10 to 15 tons, of farmyard manure supplemented with from 4 to 6 cwt. of superphosphate or basic slag, per statute acre; or the following dressing of artificials used without farmyard manure, 4 to 6 cwt. of superphosphate or basic slag, 1 cwt. sulphate of ammonia, 3 cwt. kainit, per statute acre. Basic slag must on no account be mixed with sulphate of ammonia."

[Field-crop studies] (*Wisconsin Sta. Bul. 250 (1915)*, pp. 17, 18, 19, 20, 23-28, figs. 4).—This refers briefly to the work of E. B. Fred, which has shown an injurious effect of green manures upon the germination of cotton, flax, soy beans, hemp, mustard, and lupines, apparently caused by the type of organisms connected with such soil treatment (*E. S. R.*, 28, p. 816). An increase of 20 per cent in the clover crop where sulphates were used is reported by W. E. Tottingham.

Breeding tests with peas, wheat, barley, oats, tobacco, corn, and soy beans are briefly reported.

[Breeding experiments with cereals], A. N. HUME (*South Dakota Sta. Rpt. 1913*, pp. 24-31).—This briefly gives results of selecting seed corn from plants bearing ears high above the ground and those bearing ears low, which show that there is some positive correlation between height of ear and yield. The higher growing ears indicate higher yielding strains of corn, but these are

later in maturing (up to 16 days) than the low-eared corn. Breeding corn to change the protein and oil contents, which has been previously noted (E. S. R., 32, p. 733), is also summarized here.

The breeding of small grains for increased yields (E. S. R., 30, p. 738; 31, p. 435) is briefly summarized.

Vascular bundles and their significance in the lodging of cereals, K. MOLDENHAWER (*Ztschr. Landw. Versuchsw. Österr.*, 17 (1914), No. 12, pp. 886-891).—The author here gives results of microscopical examinations of cross sections through the third internode of the plant above the root crown of 19 varieties of wheat. The number of vascular bundles in the parenchyma layer is coordinated with the bending stress for each plant.

It is noted that the number of vascular bundles seems to be a variety characteristic. Wheat varieties grown in a continental climate have a much less number of vascular bundles than those of a maritime climate. The stiffness of the culms of cereals seems to depend to a high degree upon the number of vascular bundles they possess.

The effect of different times of plowing small-grain stubble in eastern Colorado, O. J. GRACE (*U. S. Dept. Agr. Bul.* 253 (1915), pp. 15, fig. 1).—This bulletin presents data obtained during six years at Akron, Colo., and the principles deduced therefrom are believed to be of general application in the Great Plains. These data relate to spring or fall plowing for spring wheat and are discussed in an effort to show correlations between precipitation and time of plowing.

After a close study of the moisture content of the soil, the amount and time of precipitation, and yields, the author concludes that "early fall precipitation is used by weeds if land is left uncultivated until spring. Stubble prevents much of the winter snow from being blown off. The increase in soil moisture from this source usually more than compensates for the loss by weed growth of the precipitation of August and September, when such precipitation is light. Late fall plowing does not prevent the loss of early fall precipitation through weed growth, but it does destroy stubble, which would aid in holding winter precipitation. If heavy rains occur in August or September, plowing should be done immediately after they cease. If this can not be done, or if heavy rains do not occur, the land should be left in stubble until the following spring."

Meadows and pastures, J. H. VOORHEES (*New Jersey Stas. Circ.* 43, pp. 3-7).—This circular discusses soils, seed and seeding, liming, and manures and fertilizers for the establishment of meadows and pastures in New Jersey.

Growing hay in the South for market, C. V. PIPER, H. B. McCLURE, and L. CARRIER (*U. S. Dept. Agr., Farmers' Bul.* 677 (1915), pp. 22, figs. 10).—This bulletin points out the value of a hay crop for the Southern States, discusses difficulties in the way of producing market hay in the South, soils, curing the hay, and selling hay in local and city markets; describes special devices for curing hay, hay-handling devices, and hay presses; and comments upon the following crops as suitable for market hay in the cotton belt: Johnson grass, Bermuda grass, Lespedeza, or Japan clover, cowpeas, oats, Italian rye grass; the Arlington mixture of orchard grass, tall oat grass, and alsike; alfalfa, and Sudan grass.

Corn, milo, and Kafir in the southern Great Plains area: Relation of cultural methods to production, E. F. CHILCOTT, W. D. GRIGGS, and C. A. BURMEISTER (*U. S. Dept. Agr. Bul.* 242 (1915), pp. 20).—This bulletin embodies the results of a study ranging from three to seven years of methods of production of these crops at three field stations on the southern Great Plains, and includes meteorological data, a brief discussion of soil conditions, and data showing yields, value of the crop, and cost of production at the individual stations.

At Garden City, Kans., corn was not produced at a profit by any of the cultural methods tried, viz., fall plowed, spring plowed, subsoiled after corn, listed after corn, and summer tilled. At Dalhart, Tex., the profits ranged from 25 cts. by the spring plowing after small grains method to \$4.80 per acre by listing after corn. Listing is the only method to show a profit, 67 cts. per acre, at the Amarillo, Tex., station.

With milo maize grown at Garden City the lowest yield of both grain and stover was on spring-plowed land that had been continuously cropped to this crop. The highest yield was from fall plowing after small grains. The former method resulted in a loss of 83 cts. per acre and the latter a profit of \$2.07 per acre. At Dalhart, on a sandy loam soil, it gave profits ranging from \$3.58 per acre by fall plowing after small grains to \$14.21 by summer-tilled land. At Amarillo, on a heavy silty clay loam, it gave profits ranging from \$1.46 per acre on summer-tilled land to \$8.41 by fall plowing after small grains.

At Garden City Kafir corn after Kafir corn on spring-plowed land showed the lowest margin of profit, viz, 64 cts. per acre. The greatest net profit per acre, \$3.78, was secured by growing Kafir corn after small grains on fall-plowed land. At Dalhart Kafir corn produced the largest net profit, \$20.11, on land summer-tilled the preceding year. The profit of \$2.90 by the method of fall plowing following small grains was the lowest. Kafir corn was produced at Amarillo at a loss of \$2.54 per acre by the summer tillage method. The largest profit, \$8.21, was by fall plowing after small grains.

The cost per acre of the different methods of soil preparation for milo maize and Kafir corn at all stations is estimated as fall plowing after continuous cropping \$7.44, fall plowing after small grains \$7.44, spring plowing after continuous cropping \$7.06, listing after continuous cropping \$5.93, and summer tillage \$12.31. Data on the cost of producing corn have been previously reported (E. S. R., 33, p. 231).

It is noted that the greatest values in the Kafir corn crops were in the stover rather than the grain.

Forage crops, R. W. ALLEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Umatilla Expt. Farm, 1914, pp. 10, 11, fig. 1*).—This describes experiments the results of which have shown that Sudan grass, Dakota Amber sorghum, and feterita are desirable crops for that region. Dwarf Kafir corn and brown kaoliang were not so promising.

The effect on a crop of clover of liming the soil, F. W. MORSE (*Massachusetts Sta. Bul. 161 (1915), pp. 119-124*).—These experiments to study the effect of lime were begun in 1909 with the application of 3,000 lbs. of slaked lime per acre on one-half of a series of plats that otherwise received various fertilizer materials, but carried for each plat 45 lbs. of nitrogen, 80 lbs. of phosphoric acid, and 125 lbs. of potash per acre. In 1913 an additional application of lime in the form of hydrate, 4,000 lbs. per acre, was given to the limed half of the series of plats. Notes on a red clover crop grown on this series of plats during 1914 show that "the clover on the limed areas receiving no nitrogen continued to lead all the other plats in size and vigor of growth, and began to bloom several days ahead of them. The whole area receiving nitrate of soda looked uniform to the eye, but a little behind the limed area without any nitrogen. The limed areas receiving sulphate of ammonia were like the areas receiving nitrate of soda. The unlimed areas without nitrogen produced a slow-growing crop which looked scanty in comparison with the growth on the limed portions of the same plats, but an examination of the ground showed the plants to be as numerous on one area as on the other. The clover on the unlimed areas receiving sulphate of ammonia looked noticeably inferior to all other plats without lime."

Samples of the tops and of the roots of the clover plants from the several plats were gathered in September, 1914, and determinations of ash, ferric oxid, calcium oxid, and nitrogen were made. The roots from both halves of the plat receiving nitrate of soda were large and thrifty and bore numerous nodules. The roots from the limed halves of the plats receiving sulphate of ammonia and no nitrogen were apparently similar in all respects to those from the plat receiving the nitrate of soda. The roots from the unlimed half of the plat receiving sulphate of ammonia were much smaller than those from the limed half, and nodules were few and very small. The roots from the unlimed half of the plat receiving no nitrogen were thriftier than those just described, but were not so thrifty in appearance as those on the limed half and bore smaller nodules.

The composition of the clover tops from the limed areas proved to be more uniform than the composition of samples from the unlimed. The mineral constituents were slightly higher in the clover from the unlimed areas, and this was most positively defined in the percentages of calcium oxid. The nitrogen was markedly lower in the unlimed group.

"The composition of the roots differed somewhat from that of the tops. The constituents determined, except iron oxid, were much lower in percentage than those in the tops. The percentages of nitrogen varied in the same manner as in the tops, while calcium oxid was higher in the roots from limed areas, and the iron oxid was higher in those from unlimed areas. Variations in the percentages of ash in the roots were probably due in part to the presence of clay, which could not be completely washed from the roots. . . .

"The percentages of ash, iron oxid, and calcium oxid throw no light on the specific effect of liming the soil. There appears to be neither too much iron nor too little calcium in the tissues of the plants from the unlimed areas, unless the small differences in the percentages from limed and unlimed roots are sufficient to warrant such a deduction. . . .

"The results of this work point to an effect of the lime on the soil constituents, by which the root environment is improved, rather than to an effect within the plant by the absorption of a larger amount of calcium salts."

Hard clover seed and its treatment in hulling, G. T. HARRINGTON (*U. S. Dept. Agr., Farmers' Bul. 676 (1915), pp. 8*).—From studies of seeds of red clover, alsike clover, white clover, and sweet clover, grown on different soils, in different climatic conditions, covering a period of six years, and hulled by hand and by machines, after the crop had been subjected to various curing processes, the author concludes that "in nature nine-tenths or more of the well-matured seeds of red clover, alsike clover, white clover, and white sweet clover are hard.

"Hard clover seeds are sometimes of value, but are usually much inferior to good seeds which are not hard. The hardness of well-matured clover seed is not influenced materially by conditions of soil, by seasonal variations, by climatic conditions, or by the time at which the seed is harvested. The hardness of well-matured red clover seed is not related to its color or size.

"The rotting of clover in field or stack kills some of the seeds and may reduce the quality of the hulled crop, but it does not affect the proportion of hard seeds in the hulled crop after the dead seeds are removed. The rotting of the clover in field or stack or sweating it in the mow before hulling is not necessary. To secure the greatest yield and highest quality of seed the clover should be cured and stored with as little wetting as possible.

"The rubbing which clover seed receives in the hulling machine greatly reduces the proportion of hard seeds, but frequently breaks some of the seeds. The clover seed huller is, therefore, an effective scratching machine. The aim

should be to have the huller so constructed and so operated as to reduce the proportion of hard seeds to the greatest possible extent and at the same time to break the smallest possible number of seeds."

Improvement of the flax crop by propagation from selected plants, H. HUNTER (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 15 (1915), No. 2, pp. 237-246, pl. 1, fig. 1).—From experiments conducted to study some factors to consider in the improvement of flax "it has been shown that flaxseed may be artificially dried within certain limits of temperature without impairing its germination.

"Flax has been shown to be a self-fertilizing plant, directly by artificial means and indirectly by the cultivation of the seed of single plants, which was found to exhibit all the characteristics of limited variability of self-fertilizing plants when treated in a similar manner. This leads to the conclusion that the basis of the selection of parent stocks should be single plants and not groups of plants.

"Seeds of a self-fertilizing plant, when sown under similar soil conditions will demonstrate whether the characters for which the parent plant was chosen are inherent or adduced by conditions peculiar to the conditions of environment under which it was grown. Thus the true value of any selected plant must always be determined finally by the character of its progeny.

"The flaxseed in general cultivation is a mixture of many types, varying in character and degree, which are readily capable of selection and propagation as pedigreed cultures."

Investigations on hops.—III, The pollination and fertilization processes in *Humulus lupulus* and *H. japonicus*, Ö. WINGE (*Compt. Rend. Lab. Carlsberg*, 11 (1914), No. 1, pp. 46, pls. 2, figs. 22).—This article continues the report of researches previously noted (*E. S. R.*, 31, p. 526), and deals especially with the pollination processes. The results of the investigations may be summed up as follows:

"Zinger's description of the formation of the embryo sack and the growing together of the integuments in *Humulus* is correct, but the author is wrong in his statement that the ovule lacks a micropyle, the presence of which has already been determined by Lermer and Holzner.

"The microspores are developed and ripen in basipetal order in correspondence with the dehiscence of the pollen sacks by means of apical pores. It is not easy to get the pollen grains of *H. lupulus* to grow on an artificial substratum, but the pollen grains of *H. japonicus* grow willingly on a gelatin solution. The pollen grains of *H. lupulus* retain their power of growth for three days on being kept in a dry room of the laboratory. The tapetum in *Humulus* offers a good example of multinuclear cells and vegetative caryogamy, the original divalent nuclei dividing repeatedly, after which the products of division constantly fuse together. This gives rise to plurivalent, synkaryonlike nuclear complexes.

"Rosenberg and Bonnet's theory that the tapetum originates phylogenetically from the archespore and consists of sterile archespore cells can not be accepted, and for this reason it can not be admitted that atavistic tendencies give the explanation of the multinuclear condition of the tapetal cells. It is suggested that the peculiar nuclear condition of the tapetum has a physiological explanation, and the same applies to the endosperm's wealth of chromosomes. Both tissues are to a very great extent connected with the nutrition, which must be reflected in the abundance of chromatin.

"The growth of the pollen tube in *Humulus* does not suggest true aporogamy, as Zinger maintains. Zinger's description of the deep penetration of the pollen tube into the integuments is somewhat exaggerated, especially in the case of

H. japonicus. The more or less advanced age of the ovule at the moment of pollination affects the route by which the pollen tube penetrates to the nucellus, the ovule in younger flowers being less curved than in older, yet nevertheless ripe for fertilization. In younger flowers the pollen tube must pass a longer way through the integuments. In certain cases, in older flowers of *H. japonicus*, the pollen tube passes directly by the conducting tissue to the nucellus without touching the integuments.

"The number of chromosomes in the somatic cells is 20 and 16 in *H. lupulus* and *H. japonicus*, respectively; in the X-generation respectively 10 and 8. In the tetrad formation two longitudinal divisions of the chromosomes are observed, but no transverse division.

"In abnormal, monoecious hops plants of *H. lupulus* it has been found that the reduction division proceeds in the pollen mother-cells; but in the observed cases the gonotokonts then became starved, the tapetum being already degenerated. In an abnormal, gynomorphous male plant of *H. lupulus* no gonotokonts developed at all, but the microsporangia were filled with sterile tissue.

"It proved possible to produce the hybrid *H. lupulus* × *H. japonicus*, but only as an imperfectly formed embryo. The pollen tube of *H. japonicus* grew down into the ovary of *H. lupulus* in the same way as the pollen tube of *H. lupulus* itself, and the bastard embryo and bastard endosperm or only one of them developed. Humulus did not develop seed without fertilization in the experiments which were made."

Spraying and dusting white potatoes, T. J. HEADLEE (*New Jersey Stas. Circ.* 42, pp. 3-8).—This circular gives results of testing the cost and efficiency of Bordeaux mixture as a spray or as a dust, in part previously noted (E. S. R., 32, p. 547.)

Data obtained from tests in various parts of the State show that the average cost of four treatments of home-mixed Bordeaux and arsenate of lead was \$5.24 per acre, as compared with \$8.46 as the average cost of the dust treatment. The former was more effective in increasing the yield. A comparison of the home-mixed and the commercial-mixed Bordeaux shows the former to be less expensive and more effective.

Potato spraying experiments at Rush in 1914, F. C. STEWART (*New York State Sta. Bul.* 405 (1915), pp. 335-339).—This bulletin gives results of a repetition of experiments made in 1913 (E. S. R., 31, p. 137). Owing to favorable weather in 1914 potato foliage was remarkably free from diseases and injuries. The average increase in yield as a result of spraying in unsprayed fields was 8 per cent.

Mulched potatoes for seed purposes in eastern Nebraska, R. F. HOWARD (*Nebraska Sta. Bul.* 146, popular ed. (1915), pp. 3-6).—A popular edition of the bulletin already noted (E. S. R., 32, p. 631).

Potato seed certification in Wisconsin, J. G. MILWARD (*Wisconsin Sta. Bul.* 252 (1915), pp. 11, figs. 2).—This discusses the community plan of potato growing, standards for certificates based on varietal purity and freedom from disease, and methods of inspection in the field and bin. The form of certificate and a list of growers of certified seed potatoes are also given.

Results of four years' experiments with sugar cane, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucumán*, 5 (1915), No. 8, pp. 323-361).—This summarizes the results obtained with various fertilizing materials, applied in different amounts and in different combinations, as shown in the analyses of the cane juices.

Local fertilizer experiments with sweet potatoes, J. F. DUGGAR and J. T. WILLIAMSON (*Alabama Col. Sta. Bul.* 184 (1915), pp. 19-34).—This bulletin describes and gives results of fertilizer experiments made by farmers in several counties of the State during 1911, 1912, 1913, and 1914.

The data show that "of nine conclusive experiments made on various soils the largest increase in yield was afforded by phosphoric acid in five experiments, and by nitrogen in two experiments. In none was kainit more effective than acid phosphate. In five experiments cotton-seed meal was more effective than an equal weight of kainit, and in only one was kainit notably more effective than meal.

"Taken as a whole these experiments seem to indicate that the popular idea that potash is the most important constituent in a fertilizer for sweet potatoes is incorrect, at least as to practically all of the soils here represented. On the other hand, these tests show that phosphate and nitrogen were much more important than potash. These experiments also seem to discredit the notion that the use of a fertilizer containing nitrogen causes the sweet-potato plant to run to vines to an injurious extent. In our experience this danger does not occur where reasonable amounts of nitrogen are used in combination with acid phosphate.

"The following general fertilizer formulas are suggested where the conditions justify rather high fertilization: For sweet potatoes growing on fresh land, or on sandy land in rather high state of fertility, a fertilizer consisting of 200 lbs. cotton-seed meal per acre, 400 lbs. acid phosphate, and 200 lbs. of kainit. . . . For sandy land long in cultivation and not in a high state of fertility it would seem advisable to increase the proportion of nitrogen, using, for example, a formula somewhat like the following: Three hundred lbs. cotton-seed meal per acre, 400 lbs. acid phosphate, and 200 lbs. kainit."

Irrigation practice in rice growing, C. G. HASKELL (*U. S. Dept. Agr., Farmers' Bul. 673 (1915), pp. 12, fig. 1*).—This discusses methods and means of irrigation as developed in the rice fields of the United States, under the topics of making a water supply available, preparing for irrigation, and applying the water.

Growing hard spring wheat, C. R. BALL and J. A. CLARK (*U. S. Dept. Agr., Farmers' Bul. 678 (1915), pp. 16, figs. 4*).—This discusses the size, surface, soil, and climate of the Great Plains area, describes rotations for spring wheat, and gives directions for preparing the seed bed, sowing the seed, and cultivating and harvesting the crop.

Wheat silage, J. R. SHINN (*Washington Sta. Popular Bul. 88 (1915), pp. 4, fig. 1*).—This gives results of harvesting wheat or wheat and vetch as a silage crop for dairy purposes, obtained in cooperation with the Bureau of Plant Industry of this Department. The yields of silage material ranged from 6,316 to 42,688 lbs. per acre. Better milk yields are claimed by its use than by the use of corn silage.

Control of tumbling mustard, R. G. ADAMS and B. HUNTER (*Washington Sta. Popular Bul. 89 (1915), pp. 7, figs. 3*).—As methods of control of this weed, disking stubble in early fall, seeding winter wheat after and before rains, harrowing winter wheat in spring, growing spring wheat, pulling scattering mustard plants, and clipping the mustard plants are discussed, the work being in cooperation with the Bureau of Plant Industry of this Department. Attachments which may be put on the header of a combined harvester to enable the machine to cut badly infested grain are described.

HORTICULTURE.

Progress in plant breeding, N. E. HANSEN (*South Dakota Sta. Bul. 159 (1915), pp. 179-192, figs. 7*).—Descriptive notes are given on a number of varieties of fruit and on a new rose, all of which were introduced in 1912 and have been noted (*E. S. R.*, 30, p. 640).

Several varieties of pears claimed to be blight-proof have been tested at the station but either the winter or blight quickly killed them. In view of these results work has been conducted to determine whether immunity to blight existed in other members of the pear family and, if so, whether it could be imparted to cultivated pears. Of the various kinds under trial are a form of the Chinese sand pear (*Pyrus sinensis*), grown from seed collected by the author in Siberia, and the birch-leaved pear (*P. betulifolia*), a native of northern China. These two pears have proved perfectly hardy and quite resistant to blight. They have been used freely in crossing with many of the best cultivated pears. A list is given of the resulting varieties which have been sent to several States for testing purposes with reference to blight resistance and general value.

The author also briefly describes a field method of hybridizing alfalfa.

Mushrooms, edible and poisonous.—Publications on culture of mushrooms, D. C. BABCOCK (*Ohio Sta. Circ. 153 (1915), pp. 89-92, figs. 3*).—In this circular the author gives a number of rules which should be adhered to in avoiding poisonous mushrooms, calls attention to a few of the more common edible fungi, and gives a list of publications on mushroom identification and culture.

[Horticultural investigations at the Umatilla experiment farm, Oregon, in 1914], R. W. ALLEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Umatilla Expt. Farm, 1914, pp. 12-18*).—Directions are given for the management of hairy vetch as an orchard green manure crop. It has been demonstrated both at the experiment farm and by a number of orchardists that the reseeding method is thoroughly practicable and much cheaper than the annual purchase of expensive seed.

For the purpose of determining the best size of trees to purchase and the height at which they should be cut to give the best results, a number of 1-year-old cherry and pear trees of three sizes were planted in 1912. The large trees were oversize, being 1 in. in diameter and 6 to 8 ft. tall. The medium-sized lot were 3.5 to 4.5 ft. tall, and the small ones 2 to 3 ft. tall. The large, small, and part of the medium-sized trees were cut off at the usual height of 18 in. when planted. One lot of medium-sized trees was cut at 6 in. above the union and another lot left unpruned. Growth data secured from this experiment during three subsequent seasons and also from general field planting show that as far as the stone fruits are concerned large trees are undesirable for planting on account of the heavy losses that result. It has also been definitely shown that for trees planted on coarse soils better results will be obtained by cutting the trees off close to the union in order to force the first year's growth into a small number of vigorous branches. Trees left standing at full height after planting rarely survive. The trees topped at 18 in. from the ground quickly put out a large number of small branches, advance slowly, and are difficult to train.

Experiments were conducted during the past three years to determine the effect of summer pruning upon the growth and training of fruit trees. The results of this work indicate in general that removing about half the branches from bushy, slow-growing trees and removing the terminal bud of all but 6 or 8 of the remaining branches has a tendency to increase the size of weak-growing and bushy trees much faster than by winter pruning alone. This practice is believed to be important for trees on coarse soils where slow growth and early fruiting frequently occur. Heading back rapidly growing trees in summer followed by a light winter pruning tends to develop the trees more rapidly than the usual method of pruning heavily in winter at the expense of large quantities of wood growth.

A brief statement of progress is given on cultural and variety tests of fruits and vegetables. The work of testing fruit varieties has been seriously handi-

capped by poor soil conditions and spring frosts. Two poplars (*Populus alba* and *P. balsamifera suarcolens*), as well as two elms (*Ulmus pumila* and *Ulmus* sp.), and an upright willow (*Salix* sp.), all introductions by the U. S. Department of Agriculture from Asia, have given considerable promise as trees for windbreaks. They all come into leaf very early in the spring and appear to be vigorous.

The influence of grass upon the growth of orchard trees, B. T. P. BARKER (*Univ. Bristol Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 94-96, pls. 3; Jour. Bath and West and South. Counties Soc., 5. ser., 8 (1913-14), pp. 139-141, pls. 3*).—In view of the results secured in the earlier experiments at Woburn (E. S. R., 15, p. 474) and elsewhere, showing the detrimental effect of grass on fruit trees, experiments were started in 1906 under the direction of the National Fruit and Cider Institute to determine whether clean cultivation for a few feet around each apple tree would suffice to lessen or prevent the injurious grass effect. In some cases the cultivated area extended for a radius of 3 ft., in others 4½ ft., and in others 6 ft. Some of the trees were grown in grass.

The results of these tests up to 1910, six years after planting the trees, show that the growth improved with the size of the cultivated area. From 1910 to 1911 there was practically no gain from cultivation. The trees were then given no further cultivation. Measurements made in 1913 showed a tendency in many cases for trees grassed over from the start of the experiment to gain slightly on those originally cultivated. The inference based on the behavior of six varieties is that trees do benefit from cultivation and begin to show the detrimental effect of grass as soon as the roots extend out into grassed areas. Trees that have been cultivated early in life may suffer more seriously from grass later on than trees grown in grass from the start.

Similar experiments conducted in various orchards in the west of England have shown the beneficial effects of cultivation. The differences between grassed and nongrassed trees in the present experiments were not so marked as those noted in the work at Woburn (E. S. R., 26, p. 639).

Pruning, F. S. MERRILL (*Kansas Sta. Circ. 49 (1915), pp. 14, figs. 9*).—This circular contains practical suggestions for pruning orchard fruits, grapes, and bush fruits.

New developments in spray materials, W. M. SCOTT (*Amer. Agr., 95 (1915), No. 11, p. 5; New England Homestead, 70 (1915), No. 11, p. 3*).—In order to obtain a fair comparison between arsenate of lime and arsenate of lead several experiments were conducted for two years in which the former was diluted to contain the same amount of arsenic as the diluted arsenate of lead. No differences could be observed during the summer between the two insecticides, either in their effect upon the fruit and foliage or in the control of the codling moth and other insects, no injury being produced and the codling moth being controlled equally well in both cases.

It is stated that in a test by F. Johnson, formerly of the Bureau of Entomology of this Department, upon Baldwin apple trees at Westfield, N. Y., a barium-sulphur preparation, to which arsenate of lime was added, gave as satisfactory results as did the homemade lime-sulphur and arsenate of lead applied to adjacent trees, the orchard being entirely free from scab and codling moth. It is pointed out that calcium arsenate is considerably cheaper than lead arsenate and that it mixes with lime-sulphur without causing any chemical reaction. By the substitution of barium for lime as a carrier for sulphur the decomposition which takes place upon drying can be eliminated. Thus barium-sulphur furnishes a dry material which can be redissolved for spraying purposes without losing its original composition. Experiments conducted during the

past year have shown it to possess insecticidal and fungicidal properties equal to lime-sulphur.

New developments in spraying materials, W. M. SCOTT (*Rpt. Md. State Hort. Soc.*, 17 (1914), pp. 96-104).—In this paper the author reviews recent progress in the perfection of insecticides and fungicides, and gives an account of some demonstration experiments conducted to determine the value of barium-sulphur and arsenate of lime as substitutes for lime-sulphur and arsenate of lead.

The author concludes that the efficiency of these new spray materials has been sufficiently demonstrated to commend them to fruit growers for trial. The principal advantage of barium-sulphur over lime-sulphur is that the polysulphids of barium can be produced in the form of soluble crystals while those of calcium can not. The chief advantage of arsenate of lime over arsenate of lead is the cheaper cost of the former material.

Farm apple storage, M. B. CUMMINGS and P. M. LOMBARD (*Vermont Sta. Bul.* 186 (1915), pp. 99-136, pls. 4, figs. 6).—In this bulletin the authors give a short account of apple storage practice in Vermont and briefly review previous investigations dealing with the cold storage of apples. A detailed account is then given of apple storage experiments conducted during four storage seasons in a basement room resembling in many respects a farmhouse cellar. The bulletin concludes with a study of structural characters of the apple in relation to storage.

The storage experiments included several commercial varieties of apples and two distinct lines of treatment were followed. In one case the apples were dipped in Bordeaux, copper sulphate solution, lime water, or paraffin; in the other case the apples were packed in dry cork dust, dry and damp coniferous and hardwood sawdust, dry and damp leaves, dry and damp sand, chopped hay, paper wrappers, or in sawdust after being dipped in Bordeaux. The experiments were controlled with reference to ventilation and temperature and in all cases untreated parallel check lots were stored. The data secured each season are presented in tabular form and discussed.

Of the protective dips used Bordeaux was most effective in retarding decay and also in preserving the flavor. Copper sulphate gave good results in preserving flavor, but was of no value as protection against shrinkage and decay in storage. Lime water, which was used only with respect to flavor, was practically of no value. Paraffin was effective in retaining flavor and crispness, but at the same time it induced early internal decay.

All of the mechanical media used in preserving apples reduced the temperature of the fruit, but only mill sawdust and cork dust possessed value in preventing decay. Sawdust from resinous woods imparts an undesirable flavor to apples, but hardwood sawdust does not injure the flavor.

Apples kept best by first immersing them in Bordeaux and then packing them in hardwood sawdust. By this method of treatment 15 per cent of a lot of Baldwin apples stored November 11 were still in good condition on August 5, 267 days after storing, as compared with 15 per cent of the control apples in good condition on May 22, 192 days after storing, and of those dipped in Bordeaux alone and packed in sawdust alone on July 17, 248 days after storing. The flavor of apples merely dipped in Bordeaux was somewhat better than those dipped in Bordeaux and packed in sawdust. Flavor tests with the Northern Spy and Rhode Island Greening apples gave similar results for the apples dipped in Bordeaux alone. Similar results were secured with Northern Spy and Rhode Island Greening relative to the keeping tests of the above media, except that the period of storage for Northern Spy ended on July 6 and for Rhode Island Greening on July 17.

A study of the structure of the flesh and skin of several varieties of apples as compared with their keeping qualities shows that the best keeping varieties have a firm flesh, compact tissue, and a thick and highly impervious skin. The suberization and cutinization of the cuticle is a protective contrivance which is of value in prolonging the life of apples. The change in chemical and mechanical structure of the cuticular layer and the epidermis in general seems to be quite common in the late keeping varieties, like Roxbury Russet and Ben Davis. The Baldwin, a midwinter variety, has a rather porous flesh, with large intercellular spaces and a moderately thick skin. Oldenburg, a fall apple, has a relatively thin skin with thin walled cells underneath.

Report of cranberry substation for 1914, H. J. FRANKLIN (*Massachusetts Sta. Bul. 160 (1915), pp. 91-117*).—This bulletin contains a full report on the work at the cranberry substation in Wareham for the year 1914 (E. S. R., 31, p. 740).

The usual weather observations were made during the year and some evidence was secured which indicates that an increased water content of the soil tends to raise the minimum air temperature above it on cold nights. Experiments in frost protection were continued. In September a test was made of cloth such as is used in shading tobacco as a means of protecting bogs from frost. A strip of cloth was supported by wires held 3 ft. above the ground by stakes, about 9 sq. rods of rather dry grassy lowland being covered. The cloth was spread out for the tests after sundown on cold nights, the covered area being shut in on all sides. The cloth was removed soon after sunrise and the soil exposed to the heat of the day. Thermometer readings were made 5 in. from the ground under the cover and on adjoining exposed land. The results showed that the cloth gave an advantage of about 4.5° F. With the outside temperature at 26.5° there was no frost under the cover. It is believed that this advantage would be sufficient to warrant the protection in this manner of bogs yielding good returns. The first cost of protecting bogs with cloth is estimated as less than \$200 an acre, and the loss from depreciation no greater than the cost of the upkeep and operation of a pumping plant.

Work on the cranberry fertilizer plats was continued, no distinct advantage in quantity, color, and size of fruit being shown by the fertilized areas as compared with the check plats. The storage tests again showed a decrease in the keeping quality of the fruit from nitrate of soda plats. It is believed that the loss from these plats may be due to a greater shrinking of the somewhat more succulent fruit rather than to increased rotting. In 1914 two varieties were fertilized during the blooming period with a mixture of 150 lbs. per acre of nitrate of soda, 400 lbs. of acid phosphate, and 200 lbs. of high-grade sulphate of potash. Data secured in yield and size of fruit indicate that the application of fertilizer during the blooming period tends to cause a greater number of blossoms to set and mature fruit. The same result was observed in the application of nitrogenous fertilizers during the blooming period in 1913.

The bee pollination experiments were discontinued. Some preliminary observations of studies of the seasonal development of the root growth of cranberries and of Mycorrhiza fungi on cranberry roots are noted. Observations made at the harvesting period indicate that the average loss of berries with careful scooping is about 10 per cent as compared with an extreme loss of 25 per cent from hurried scooping. It is believed that under normal price conditions it will pay to scoop heavy or medium crops slowly and carefully. Observations on the temperature of June reflowage water with reference to bud injury have shown that water at 86° causes practically no damage to the buds. It is believed that higher temperatures will seldom be experienced in flooding.

The season's work with plant diseases and insects is noted on pages 350 and 352, respectively, and a study on water movement in peat on page 322.

State bog report, H. J. FRANKLIN (*Ann. Rpt. Cape Cod Cranberry Growers' Assoc.*, 27 (1914), pp. 5-27).—A summarized account of the above noted work at the cranberry substation.

[Cranberry investigations] (*Wisconsin Sta. Bul.* 250 (1915), pp. 28, 29).—

A brief statement of progress in the station's cranberry work (E. S. R., 31, p. 835).

The results of the clean culture method of cranberry bog culture—that is, sanding and draining—continue to demonstrate the efficacy of this mode of cultivation in comparison with the older methods of bog management. Most of the new bogs in the State are being installed on the clean culture basis. The attempt of growers to reclaim old bogs by sanding on top after partial attempts at weeding and without adequate drainage minimizes materially the advantage of the clean culture process, since the retained moisture facilitates luxuriant moss growth.

An inspection of most of the Wisconsin bogs by C. L. Shear resulted in the conclusion that the so-called blight, which apparently prevents the development of much of the fruit after blossoming (E. S. R., 31, p. 840), is really due to lack of vitality of the vines caused by improper cultural conditions, more especially insufficient drainage.

The avocado in California.—I, Culture, production, and marketing, I. J. CONDIT (*California Sta. Bul.* 254 (1915), pp. 381-394, figs. 9).—In this paper the author discusses the avocado with reference to its general distribution, economic importance, climatic requirements, propagation and culture, production and marketing, insects and diseases, and varieties.

Botanical characters of the leaves of the date palm used in distinguishing cultivated varieties, S. C. MASON (*U. S. Dept. Agr. Bul.* 223 (1915), pp. 28, pls. 5, figs. 15).—The results are given of a study of the foliage characters of the date palm, the object of the study being to develop a classification of characters adapted to determining varieties. The system of classification devised is here explained, together with the method of recording characters. Descriptions are also given of four varieties of the Deglet Noor date showing the application of this system of leaf study.

Mangoes in Florida, P. H. ROLFS (*Florida Sta. Bul.* 127 (1915), pp. 105-138, figs. 19).—A practical treatise on mango culture. Consideration is given to the history and range of mango culture in Florida, time of ripening and blooming, methods of propagation, effects of stock on scion, culture, fertilization, marketing, mango groups and varieties, and culinary recipes. A short bibliography of literature on mango production is appended.

FORESTRY.

Forest planting in Vermont as an investment, A. F. HAWES (*Vermont Sta. Bul.* 188 (1915), pp. 261-294, pls. 4).—A cultural treatise including a discussion of the possibilities of forest planting in Vermont as an investment. The subject matter is discussed under the following general headings: Suggestions for the prospective forest planter, land which should be reforested in Vermont, safety of an investment in forest planting, kind of trees to plant, methods of planting, convenient planting crew, time of planting, spacing, esthetic planting, cost of planting, care of forest plantation, taxation on forest plantations, returns from plantations, profit from forest planting, value of land that can be planted profitably, cost of raising pine lumber, and school-endowment forests.

The text is given of the Vermont act of 1912 relating to the taxation of young timber, as well as the act of 1912 providing for school-endowment forests. Data on the height and diameter growth of white pine, Norway pine, balsam fir, and white ash are appended.

The cypress and juniper trees of the Rocky Mountain region. G. B. SUDWORTH (*U. S. Dept. Agr. Bul. 207 (1915), pp. 36, pls. 37*).—This bulletin describes the distinguishing characters, geographic distribution, and forest habits of all the known species of cypress (*Cupressus*) and junipers (*Juniperus*) growing within the Rocky Mountain region of the United States, including also Canadian territory lying directly north of the Rockies and Mexican territory adjacent to the Southwest. The descriptive text is accompanied by illustrations representing foliage, fruits, seeds, and other important parts of the trees in their natural size as well as maps showing the geographical distribution of the different species.

Caoutchouc. A. J. ULTÉE (*Caoutchouc. Haarlem: H. D. Tjeenk Willink & Son, 1913, pp. VIII+93, figs. 38*).—A treatise on the culture, diseases and pests, tapping, and preparation of rubber with special reference to *Hevea brasiliensis* and *Ficus elastica*. Notes are given relative to vulcanization, regeneration, and rubber surrogates, together with statistics of rubber production and consumption in different countries.

Cinchona culture. A. GROOTHOFF (*De Kinacultuur. Haarlem: H. D. Tjeenk Willink & Son, 1912, pp. 111, figs. 30*).—A treatise on cinchona with reference to the history of the industry, the introduction of the cinchona tree into Asia, its botany and culture, the exploitation and preparation of the bark, uses and commerce, and geographical distribution of the industry.

Union of an oak and a birch. W. T. DAVIS (*Proc. Staten Isl. Assoc. Arts and Sci., 5 (1913-14), No. 1-2, p. 10, pl. 1*).—An illustration with descriptive notes is given of a white oak (*Quercus alba*) and black birch (*Betula lenta*) that have grown together in such a manner that if the trunk were all that could be seen they would ordinarily be taken for one individual.

Union of an oak and a beech. A. HOLLICK (*Proc. Staten Isl. Assoc. Arts and Sci., 5 (1913-14), No. 1-2, pp. 11, 12, pl. 1*).—An illustration with short descriptive notes is given of a white oak (*Quercus alba*) and a beech (*Fagus americana*) which have grown together at the trunk similar to the above-noted trees.

Notes on the germination of some tree and shrub seeds. W. KINZEL (*Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 4-5, pp. 129-159*).—During the course of the author's investigations during the past 10 years relative to the effect of frost, light, and other influences on the germination of seed of various kinds (*E. S. R.*, 26, p. 821; 29, p. 421), germination tests were made of the seed of a number of trees and shrubs of diverse species. The present article comprises observations on the germination history of these trees and shrubs, with special reference to the development, ripening, and resistance faculty of the seed of indigenous and cultivated forms of linden.

The application of town sewage and house garbage as a forest manure. SCHWAPPACH (*Ztschr. Forst u. Jagdw., 47 (1915), No. 4, pp. 249-256*).—Experiments conducted in the neighborhood of Berlin in the use of sewage waters diluted by rain water and of house garbage indicate that an important increase in size may be obtained in various hardwoods by irrigations with sewage water, but that such irrigation should be confined to the first few years in the life of pine and spruce trees and is apt to cause damage to all evergreen trees after a few years' time. The trouble appears to be due rather to a change in the level of the ground water than to any specific injury from the sewage water. The

use of garbage wherever feasible appears to be desirable, since it increases the moisture content of the soil and furnishes available plant food for the trees.

Annual progress report on forest administration in the Western, Eastern, and Kumaun Circles of the United Provinces for the forest year 1913-14, H. G. BILLSON, J. C. TULLOCH, and F. CANNING (*Ann. Rpt. Forest Admin. West., East., and Kumaun Circles [India], 1913-14, pp. 5+57+XC+S*).—This is the usual report on the administration, management, silvicultural operations, and exploitation of the state forests in the Western, Eastern, and Kumaun Circles of the United Provinces, including a financial statement for the forest year 1913-14.

All important data relative to the forest areas, forest surveys, working plans, forest protection, and miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Progress report of forest administration in the Punjab for the year 1913-14, R. MCINTOSH (*Rpt. Forest Admin. Punjab, 1913-14, pp. 7+II+20+CLX*).—A report similar to the above on the administration of the state forests in the Punjab, including also a quinquennial review.

The production of lumber in 1913 (*U. S. Dept. Agr. Bul. 232 (1915), pp. 32, figs. 2*).—A statistical report on the production of lumber in the United States in 1913, prepared by the Forest Service in cooperation with the Bureau of Crop Estimates.

Detailed data are given showing the production of the important kinds of lumber by States and the number of active mills in each State, together with data showing the total production of minor species of lumber and the principal States reporting same. Comparative summaries of production by States and species are given for 1913, 1912, and 1911.

In 1913 a total production of 38,387,000,000 ft. b.m. was reported, as compared with 39,158,414,000 ft. in 1912. Soft woods contributed 30,302,549,000 ft. b.m. in 1913, as compared with 30,526,416,000 ft. in 1912.

DISEASES OF PLANTS.

[Investigations in plant diseases] (*Wisconsin Sta. Bul. 250 (1915), pp. 33-39, figs. 4*).—A summary report is given of work carried on by the department of plant pathology during the year, the investigations consisting of a plant disease survey, and experiments with rot-proof cabbage, onion smut, and pea blight.

In connection with the plant disease survey a new disease of cucumber, known as "white pickle," has been discovered. It affects both vine and fruit, causing serious losses. The cause is as yet undetermined.

In continuation of the experiments in the production of cabbage immune to the disease known as yellows, one strain has been developed and seed placed in the hands of selected growers. A stand of from 95 to 99 per cent of the rot-proof type was obtained, as compared to 15 to 20 per cent of a crop where imported Danish and Puget Sound seed was used. Efforts are being made to produce a seed of this resistant strain on a commercial scale in the Puget Sound region.

A continued investigation on the prevention of onion smut by the use of formaldehyde solution has shown that the treatment greatly reduces the amount of disease at a cost of about \$4 per acre for the fungicide and its application.

The pea-blight investigation during the year has been extended to study the influence of drainage. Where land that had been previously cropped with peas was thoroughly drained but little blight was observed, while on the

undrained portions of the same plot a total loss was experienced. Preliminary investigations have been begun on the development of a resistant strain of plants. A survey made of the pea industry indicates that a lack of rotation is one of the chief contributory factors in the production of pea blight.

Lightning injury to potato and cotton plants, L. R. JONES and W. W. GILBERT (*Phytopathology*, 5 (1915), No. 2, pp. 94-102, pls. 2; *abs. in Phytopathology*, 4 (1914), No. 6, p. 406).—The results of an inquiry into the injury caused by lightning are given, the authors stating that such injury is not uncommon to certain crops, particularly cotton, potatoes, beets, tobacco, and ginseng.

Relation between Puccinia graminis and plants highly resistant to its attack, E. C. STAKMAN (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 193-200, pl. 1).—In amplification of an account previously noted (E. S. R., 33, p. 245), the author gives some results of histological studies of the hyphal invasion of several plants by *P. graminis*.

It is stated that when plants practically immune to *P. graminis* are inoculated the fungus gains entrance in a perfectly normal manner. After entrance it rapidly kills a limited number of the plant cells in its immediate vicinity and seems then unable to develop further.

The relations between plant and parasite in partially resistant and in almost totally immune plants are different in degree only, hypersensitiveness appearing to be a phenomenon fairly common among both somewhat resistant and almost totally resistant plants.

A bibliography is given.

A preliminary report on the relation of grass rusts to the cereal rust problem, E. C. STAKMAN (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 411).—In continuation of previous studies on rust specialization (E. S. R., 31, p. 146) the author reports experiments in which uredospores developed on grasses in the field were used to inoculate wheat, oats, barley, and rye. It was found that *Puccinia graminis* from *Agropyron repens*, *A. tenerum*, *A. caninum*, *A. smithii*, and *Hordeum jubatum* transferred quite readily to barley and rye, only occasionally to wheat, and practically not at all to oats. The rust transfers readily from *Dactylis glomerata* and *Poa nemoralis* to oats, but not to other cereals.

Attempts were made to transfer rusts occurring on *Agrostis alba*, *A. stolonifer*, *Antho.ranthum odoratum*, *Calamagrostis canadensis*, *Poa pratensis*, and *P. compressa* to wheat, oats, barley, and rye, but, with the exception of a few small spores and a very few pustules, the results were entirely negative.

The ascigerous stage of Helminthosporium teres, A. G. JOHNSON (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 408).—In the course of studies on the Helminthosporium diseases of barley the author found an ascigerous stage which is considered to be a species of Pleospora.

Some facts of the life history of Ustilago zeæ, F. J. PIEMEISEL (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 411, 412).—The author reports inoculation work with sporidia of *U. zeæ* which indicates that infection may take place readily without any injury of the tissues, and that the infection is purely local. On very young corn plants successful infection often takes place, but not much of the host tissue is involved. No effect of freezing temperature on the vitality of spores was observed. Spores placed in a silo in the fall failed to germinate within two months from the time they were placed in the silage, but whether they germinated in the silo or whether the various organic acids which are developed during fermentation of the silage destroyed their powers of germination has not been definitely determined. It is considered, however, that the acids probably are the chief agency in destroying the powers of germination.

Third progress report on *Fusarium*-resistant cabbage, L. R. JONES (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 404).—The author reports trials conducted in experimental fields as well as in cooperative tests with farmers of strains of cabbage which were previously reported (*E. S. R.*, 31, p. 446) as resistant to the cabbage yellows fungus.

Compared with the commercial strains, practically all plants lived and headed, giving a very large increase in production. It is considered justifiable to conclude that the disease-resisting quality which has shown itself in three successive generations is a fixed transmissible character.

The relation of temperature to the infection of cabbage by *Fusarium conglutinans*, J. C. GILMAN (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 404).—In connection with investigations on *Fusarium* disease of cabbage by Jones (*E. S. R.*, 31, p. 446), the author found that the disease was induced by a soil temperature of from 17 to 22° C. or above, while no disease was found in flats and pots with soil from the same field but kept at 14 to 17°. These experiments indicate that the organism is dependent on a rather high soil temperature to produce infection.

Cotyledon infection of cabbage seedlings by the bacterial black rot, C. DRECHSLER (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 401).—The author reports that cabbage seedlings grown in soil that had been previously inoculated with *Pseudomonas campestris* were frequently found attacked by black rot. Specialized water pores are not found on cabbage seedlings, and until they are developed on the secondary leaves the cotyledons may function in guttation and bacteria enter through the stomata. The points of original infection are limited to the area active in guttation. The disease was also induced by inoculating droplets extruded by the cotyledons.

A disease of red clover and alsike clover caused by a new species of *Colletotrichum*, P. J. O'GARA (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 410).—The author describes a widely spread disease in the State of Utah on red and alsike clovers. The plants are attacked most frequently at or near the crown, but the fungus may also attack the stems just beneath a cluster of blossoms, as well as the petioles and stipules. A technical description of the fungus, which is a species of *Colletotrichum*, has been noted (*E. S. R.*, 32, p. 842).

A disease of the underground stems of Irish potato caused by a new species of *Colletotrichum*, P. J. O'GARA (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 410, 411).—According to the author, a disease of potatoes which may become of economic importance was observed in the Salt Lake Valley, Utah. While examining some badly diseased fields many plants were found to have dark brown or black cankers or lesions on the underground stems, the stems often being completely girdled. The organism causing the trouble has been isolated and a technical description of it is given elsewhere (*E. S. R.*, 32, p. 842).

"Spindling sprout" of potatoes, F. H. HALL (*New York State Sta. Bul.* 399, popular ed. (1915), pp. 4, fig. 1).—This is a popular edition of Bulletin 399 previously noted (*E. S. R.*, 33, p. 52).

A contribution to the life history of *Spongospora subterranea*, L. O. KUNKEL (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 265-278, pls. 5).—In a preliminary report the author describes a type of infection supposed not to have been noted heretofore.

Infection of growing potatoes by *S. subterranea* is accomplished not by separate amœbæ, as previously supposed, but through the action of an invading plasmodium infecting a large number of cells at each point of entrance. This raises numerous questions regarding various related organisms.

It is noted that the cells in each little area of infected tissue are stimulated to abnormal growth and division. In stored tubers spores germinate in the base

of the old sori and produce amoebæ, which come together to form plasmodia that cause secondary infections. These plasmodia feed on surrounding tissue, causing a dry rot, which is probably a mild form of the canker stage.

The spores germinate in culture media, each producing a single uninucleate amoeba, and this body encysts, entering a resting stage, when conditions become unfavorable. Apparently saprophytic plasmodia are produced on culture media.

A bibliography is given.

Soil stain and pox, two little known diseases of the sweet potato, J. J. TAUBENHAUS (*Abs. in Phytopathology, 4 (1914), No. 6, p. 405*).—Soil stain or scurf, which was first described by Halsted (E. S. R., 2, p. 416), was attributed to *Monilochaetes infuscans*, but the author has carried on some investigations which indicate that the genus *Monilochaetes* is probably not well founded. Affected potatoes are considerably reduced in value, the disease being confined to the underground parts and carried with the seed. It is said that it may be easily controlled by soaking the seed (roots) for 10 minutes in a solution of corrosive sublimate. It may also be eliminated by growing plants from vine cuttings.

The second disease reported upon was also described by Halsted (E. S. R., 2, p. 416) and attributed by him to *Aerocystis batatae*. During two years' work of the author's on this disease this fungus has not been found associated with it. A *Fusarium*, an *Actinomyces*, and a *Rhizoctonia* were isolated, and it was found that an excess of lime favored the disease, while an acid fertilizer such as acid phosphate reduced it.

Some important leaf diseases of nursery stock, V. B. STEWART (*New York Cornell Sta. Bul. 358 (1915), pp. 167-226, figs. 29*).—This is a condensed report of investigations since 1909 on nursery leaf diseases and means of protection therefrom. These include apple scab (*Venturia inaequalis*), pear scab (*V. pyrina*), apple powdery mildew (*Podosphaera oxycanthæ* or *P. leucotricha*), yellow leaf disease of cherry and plum, ascribed by Higgins (E. S. R., 29, p. 349; 30, p. 750) to *Coccomyces* spp. (polymorphic forms of *Cylindrosporium*), powdery mildew of cherry (*P. oxycanthæ*), anthracnose of currants and gooseberries (*Pseudopeziza ribis*, parasitic stage *Glæosporium ribis*), *Septoria* leaf spot of the same plants (*S. ribis*), gooseberry mildew (*Sphaerotheca mors-uræ*), leaf blotch of horse chestnut (*Lastadia æsculi*, conidial and parasitic form *Phyllosticta parvæ*), peach leaf curl (*Eoascus deformans*), leaf blight of pear and quince (*Fabraa maculata* [*Stigmatæa mespili*], parasitic stage *Entomosporium maculatum*), *Septoria* leaf spot of pear (*Mycospharella sentina*, conidial stage *S. piricola*), black spot of roses (*Diplocarpon rosæ*, conidial stage *Actinonema rosæ*), and mildew of rose and peach (*Sphaerotheca pannosa*, conidial form *Oidium leucoconium*).

A promising new fungicide, W. M. SCOTT (*Abs. in Phytopathology, 4 (1914), No. 6, p. 412*).—The author briefly reports upon some experiments on the use of barium polysulphid in crystal form for the control of apple scab. Spraying experiments were conducted, the fungicide being used at the rate of from 3 to 6 lbs. to each 50 gal. of water in comparison with lime-sulphur solution. No outbreak of apple scab occurred on any of the checks, so that the value of the fungicide could not be determined for the control of the disease.

In peach-spraying experiments the barium sulphur used at the rate of 3 lbs. to 50 gal. of water controlled peach scab almost completely.

The author concludes that this material has decided fungicidal properties and is worthy of further investigation.

Apple cankers and their control, L. R. HESLER (*New York Cornell Sta. Circ. 28 (1915), pp. 17-28, figs. 16*).—Brief popular descriptions are given of the various forms of canker of apple trees found in New York State with sugges-

tions for their control as far as definite means are known. In addition to frost cankers and sunscald, the forms of canker and their causal agents taken up are apple tree canker (*Physalospora cydoniae*), fire blight canker (*Bacillus amylovorus*), European apple tree canker (*Nectria ditissima*), Illinois blister canker (*Nummularia discreta*), bitter rot canker (*Glomerella cingulata*), and a superficial bark canker caused by *Myrosporum corticolum*.

Field studies of apple rust, N. J. GIDDINGS and A. BERG (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 401).—In continuation of previous studies (E. S. R., 28, p. 748), the authors give the results of experiments undertaken for the control of the apple rust.

The results indicate that it is impracticable to control this disease in commercial orchards by use of liquid sprays, as spray material applied a week previous to infection did not appreciably reduce the amount of disease. Of the fungicides tested, commercial lime sulphur gave the best results, with Bordeaux mixture second and atomic sulphur third.

Orchards were found infected to a considerable extent three-fourths of a mile from any cedar trees, and the effects of a severe rust infection, it is claimed, may be noted on trees for at least two years following it. There is believed to be some evidence that heavy infection of a cedar tree is followed either the first or second season afterwards by a loss of vitality and inhibition of growth, which renders that tree practically immune for one or two seasons.

Apple rots, C. BROOKS, D. F. FISHER, and J. S. COOLEY (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 403).—The authors report having isolated from market and storage apples the following fungi which are capable of producing a rot of the same: *Sphaeropsis malorum*, *Glomerella cingulata*, *Monilia* sp., *Botrytis cinerea*, *Phomopsis mali*, *Penicillium expansum*, *P. commune*, *P. pinophilum*, *Mucor stolonifer*, *Cephalothecium roseum*, *Aspergillus niger*, *Trichoderma* sp., *Pestalozzia gucchini*, *P. brevipes*, *Verticillium* sp., *Ramularia macrospora*, *Fusarium radicolola*, *F. putrefaciens*, and several species or strains of *Alternaria*.

Of the above species, *P. expansum* is the most common on the storage fruit. *Sphaeropsis* and the *Alternarias* cause most of the blossom rot in eastern States, and the *Alternarias* and the *Fusariums* the core rots in the Northwest. The *Alternarias* are also of common occurrence following Jonathan spot and scald.

York spot and York skin-crack, H. S. REED (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 405).—The author reports some new, or at least undescribed, troubles observed in Virginia in 1914 on the York Imperial apple.

The spot appears somewhat different from the Jonathan spot and is characterized by much larger sunken areas on the fruit, which bear some resemblance to moderate hail injury. The tissue beneath the spots is dry and corky. Where the trouble is severe the superficial tissues are water-soaked.

York skin-crack was first noticed by the author in 1911, but did not become serious until 1914. The skin of the fruit is at first pitted and then cracks open, giving entrance to various decay fungi. There is a rather constant association of a species of *Alternaria* with this trouble, and this fungus has been isolated and is now under further study.

Orchard experiment with Jonathan spot rot in 1914, G. W. MARTIN (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 406).—In continuation of a previous report (E. S. R., 29, p. 847) the author bagged apples, as in the previous investigation, and compared the protected with the unbagged apples. The results obtained are in harmony with those of 1913, which indicate that Jonathan spot rot is caused by a species of *Alternaria* and that infection occurred later than June 9.

Jonathan spot, bitter pit, and stigmonose, C. BROOKS and D. F. FISHER (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 402, 403).—Experiments of the authors have shown that both Jonathan spot and bitter pit are usually worse

on large apples than on small ones, and that bitter pit is increased by continued heavy irrigation, by continued light irrigation, or by sudden checks in the water supply to heavily watered trees. If a sudden drought comes at mid-season the effects may become more extreme than in typical bitter pit, the fruit developing large dead areas beneath the skin, with a very high coloration on the surface, while the fruit is still green. In such cases drops of sticky exudation often appear on the affected areas and the fruit ripens prematurely.

Stigmonose is a term used to refer to the response to insect attack, and in the apple one form seems to be closely associated with the occurrence of the rosy aphid. It differs from bitter pit in that it develops earlier in the season, occurs on the fruit in the middle of the tree rather than on the exposed limbs, is often followed by cracking of the fruit and premature ripening, is often accompanied by a gnarled appearance of the apple, the spots are not typically at the end of vasculars, and the brown tissue beneath has more definite margins and is firm rather than spongy.

Stigmonose: A disease of fruits, M. B. WAITE (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 402).—The author reports having observed in and under the skin of Japanese plums, pears, and apples a disease which he designates as stigmonose.

On pears stigmonose forms a hard, sunken, slightly atrophied, greenish spot, and in late pears it may become brownish. In apples a similar sunken, greenish spot is produced, the spot later becoming corky and dry, resembling bitter pit. In plums the spots remain firm and hard, although possibly streaked with brown after the fruit ripens.

Plant bugs and aphids are considered as having an important part in the formation of these injuries, and the stigmonose effect has been observed on the apple around curculio feeding punctures and scars made by the ovipositor.

Common diseases of apples, pears, and quinces, M. T. COOK (*New Jersey Stas. Circ. 44*, pp. 20, figs. 18).—This is a descriptive list of common diseases of pomaceous fruits, with treatments. A discussion is also given of water core, winter injury, and spray injury, also of spraying, with reference to the organism to be controlled, the material to be used, and the time of application. A spray calendar is appended.

Common diseases of the peach, plum, and cherry, M. T. COOK (*New Jersey Stas. Circ. 45*, pp. 16, figs. 10).—Besides a discussion of the most common diseases of drupaceous fruits in this State, and treatments so far as known, a description is given of injuries due to cold, sprays, and constriction by label wires, said to cause symptoms like those of yellows. Spray calendars adapted to the peach, plum, and cherry are also given.

A preliminary report on twig and leaf infection of the peach by means of inoculations with *Cladosporium carpophilum*, G. W. KEITT (*Abs. in Phytopathology*, 4 (1914), No. 6, pp. 408, 409).—The author reports successful infection experiments with *C. carpophilum* taken from leaves and twigs, more than 50 lesions being counted on twigs and more than 100 on leaves. On the control plants only one primary twig infection developed and no primary leaf infection was found.

Fungus-host relationship in black knot, E. M. GILBERT (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 402).—A microscopical study of the formation of black knot gall shows that a considerable portion of the hypertrophy is in regions not directly in contact with the fungus. The continued invasions of the fungus hyphæ cause a separation of cells into larger and small masses, and during this process some of the cells gradually fill with a granular substance which becomes resinous in nature and is exuded from the mature knot. Other cells disintegrate, the cell walls break down, cytoplasm disappears, and at this

time it is not uncommon to find the host nuclei lying free between the hyphæ of the fungus.

The perfect stage of the fungus of raspberry anthracnose, W. H. BURKHOLDER (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 407).—During 1914 the author made an examination of the affected stems which showed minute pustules on the diseased area. From these were developed cultures the same as those from conidia of the anthracnose fungus (*Glcosporium venctum*). The morphology of the fungus on raspberries seems to be identical with that found by Woronichin upon *Pyrus*, which is attributed to *Plectodiscella piri*.

[Fungus diseases of cranberries], H. J. FRANKLIN (*Massachusetts Sta. Bul.* 160 (1915), pp. 94-100).—A report is given of investigations carried on in cooperation with C. L. Shear, of the Bureau of Plant Industry of this Department, the general plan being the same as that previously described (E. S. R., 31, p. 740).

Experiments for the control of diseases by spraying with Bordeaux mixture have been continued, but no evidence was obtained to indicate that spraying is beneficial, and under some conditions it was apparently injurious to the crop. Indifferent results were obtained in an attempt to determine whether the keeping qualities of the fruit in a sprayed plat were better than those where the plants were not sprayed. The use of copper sulphate placed in flowage water was again tested without definite results. The berries from the treated sections, however, showed a smaller percentage of loss in storage than the untreated ones.

The effect of spraying on root development of cranberry plants was studied, and the results obtained seemed to suggest that the plants are injured by retarding the development of new rootlets. In order to determine definitely the effect of Bordeaux mixture a series of plats were sprayed in various ways, excessive quantities of the fungicide being employed. It seems that spraying for the control of fungus diseases in the Cape Cod bogs is impracticable unless some noninjurious substitute for Bordeaux mixture can be found.

Notes are given on the disease commonly called ringworm, which, instead of being the result of insect work, seems to be due to the attack of fungi. The author also reports the occurrence of the Wisconsin false blossom disease (E. S. R., 31, p. 841) in bogs in Massachusetts. In every instance the presence of the disease was traced to vines that had come from Wisconsin.

Rhizoctonia in America, G. L. PELTIER (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 406).—While making a study of the stem rot of carnation, due to *Rhizoctonia*, the author collected about 50 forms of the fungus.

After three seasons' work with these cultures he finds that while some exhibit slight morphological differences, in cross-inoculation experiments they all behave alike. All but two of the forms, he claims, can be included under *R. solani*. The author states that true *R. violacea* of Europe has not been reported in this country. There seems to be no question that *Hypochnus solani* of Europe is the same as *Corticium vagum solani*.

An anthracnose of *Asclepias speciosa* caused by a new species of *Colletotrichum*, P. J. O'GARA (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 410).—A brief account is given of a disease of stems and foliage of the common milkweed in the Salt Lake Valley. A technical description of the fungus has been given elsewhere (E. S. R., 32, p. 842).

Some effects on chestnut trees of the injection of chemicals, CAROLINE RUMBOLD (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 412).—The author injected a number of stains into living chestnut trees to determine their diffusion throughout the tree. When injected into the trunks the solutions were found to have passed up and down in restricted areas. Branches and roots on the

injected side would be stained, while the uninjected side was not. The stains were also found to differ in their method of passage through the tissue. Methyl green passed through the trachæ in the last year's ring of wood. Congo red and trypan blue spread over larger areas. Colloidal stains spread further through the trees than crystalloidal ones. The chemicals, whether metals, acids, alkalis, or benzenes, appear to have profoundly affected cells lying beyond the paths of the injected solutions, causing pathological growth.

Leaves on the injected tree showed blotches which were found to be characteristic of the chemical used. In the case of lithium-injected trees, the presence of the metal was found in bark, leaves, and fruit.

Notes on *Cronartium comptoniæ* and *C. ribicola*, P. SPAULDING (*Abs. in Phytopathology*, 4 (1914), No. 6, p. 409).—In continuation of a previous account of observations on one of these fungi (E. S. R., 30, p. 653), the author reports that *Pinus rigida* is very susceptible to attacks of *C. comptoniæ*, and that both *P. ponderosa* and *P. contorta* were so badly affected that the entire stock of both species in a nursery was destroyed. The fungus has been successfully transferred from *P. contorta* to *Comptonia asplenifolia*, but not from *P. laricio*, another new host.

In addition the author reports *C. ribicola* on the American variety Downing of cultivated gooseberries.

Observations on the pathology of the jack pine, J. R. WEIR (*U. S. Dept. Agr. Bul.* 212 (1915), pp. 10, pl. 1, figs. 4).—This is a study of fungi affecting *Pinus divaricata*, chiefly in Michigan, Minnesota, and adjacent Canada.

Peridermium cerebrum (*Cronartium quercus*) causes the most important injury to jack pine of all ages, attacking almost all portions of the trunk and usually either killing or dwarfing the plant attacked.

Wood-destroying fungi of the living tree are not regarded as very important, though a few are mentioned, as *Trametes pini* and *Polyporus schweinitzii*, which attack weakened trees. A number of saprophytic fungi mentioned attack dead wood of this species, which rapidly deteriorates in consequence.

A new leaf and twig disease of *Picea engelmanni*, J. R. WEIR (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 251–254, pl. 1).—In a preliminary statement the author reports having examined what was thought from the gross appearance of the mycelial mat to be *Herpotrichia nigra*, a fungus common on *P. engelmanni* on Marble Mountain, Idaho. It proved, however, to be a new species which is described as *H. quinquesepitata* n. sp. These two species of *Herpotrichia*, with *Neopeckia coulteri*, cause considerable damage to forests at altitudes of not less than 5,000 ft. The dense mat of mycelium has been found to influence the temperature of the enveloped leaves in the same manner as when any dark covering is placed on an air thermometer bulb. The fungus acting as a pronounced epiphyte may thus be enabled to incubate its own mycelia within the tissues of the host, thus hastening its parasitic activities, and these may be further hastened by accompanying injurious physiological changes. The spread of the mycelium over young growth, from spring to early fall, is fairly rapid.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

[Report on insect pests] (*Wisconsin Sta. Bul.* 250 (1915), pp. 29–33, fig. 1).—Brief notes are presented on cranberry insect work by O. G. Malde, and on studies by J. G. Sanders on the control of the onion maggot (see p. 357); the tobacco split worm, better known as the potato tuber worm, which was found during the year to occur in the State; May beetles (*Lachnosterna* spp.);

the cottony maple scale, which became so numerous as to be destructive to many soft maple shade trees in a number of cities and farming communities; etc. It is stated that upon a farm where the poisoned bait spray for the onion maggot was tested, a perfect stand of onions was secured, while an untreated check plot 40 ft. distant and separated by two rows of trees and currant bushes was destroyed by the onion maggot to the extent of 75 per cent. A chart illustrating the development and vulnerable points of attack of the May beetle is included.

Potato insects, R. L. WEBSTER (*Iowa Sta. Bul. 155 (1915), pp. 359-420, figs. 43*).—Brief accounts with records of observations are given of the important insect enemies of potatoes in Iowa. The pests considered are the Colorado potato beetle, the potato flea-beetle (*Epitrix cucumeris*), the striped blister beetle, the gray blister beetle, the black blister beetle, the tobacco worm, the tomato worm, the cabbage looper, the variegated cutworm, the cotton cutworm (*Prodenia ornithogalli*), the apple leafhopper, the potato aphid (*Macrosiphum solanifolii*), the dusky leaf bug (*Adelphocoris rapidus*), the tarnished plant bug, the potato stalk borer, and white grubs.

A bibliography of literature relating to the subject is included.

[Work with cranberry insects in 1914], H. J. FRANKLIN (*Massachusetts Sta. Bul. 160 (1915), pp. 193-117; Ann. Rpt. Cape Cod Cranberry Growers' Assoc., 27 (1914), pp. 12-27*).—In reporting upon the occurrence during the year of insect enemies of cranberries, in continuation of work previously noted (E. S. R., 31, pp. 453, 752), it is stated that the forest tent caterpillar was very abundant everywhere in the cranberry section during May and June, but that it was never found feeding on cranberry vines. While the army worm was abundant and did quite a little damage on bogs here and there the cases of great injury appear to have been few. The gipsy moth is becoming more of a menace each year. The cranberry weevil (*Anthonomus suturalis*) which did much damage on some bogs at Plymouth in 1913 also caused a loss in the same locality in 1914. The application of arsenicals when the vines were in bud some time before any blossoms have opened appears to have reduced the injury caused. The spanworm (*Epelis truncataria faxonii*), which seriously damaged a bog at Wareham, was found to be parasitized by an ichneumonid, to be described by the author as *Campoplex variabilis* n. sp., to the extent of 25 to 30 per cent. The larvæ are said to have survived a winter submergence of five months in the bog. The cranberry tip worm (*Cccidomyia oryococcana*) and the cranberry fruit worm were given special attention during the year and are here considered at some length. Notes are also given on the flowed bog fireworm or blackhead cranberry worm (*Rhopobota vacciniana*).

It was determined that the cranberry tip worm is responsible for the poor budding that follows the serious dying back of the cranberry tips, which had been supposed to be due to injury to the root system caused possibly by mismanagement in the use of water during the growing season. It was found that the maggots of the most injurious brood leave the tips and go down to the sand under the vine to form their cocoons. Flowed bogs which had been resanded the fall before or in the spring before the first of May were, as a rule, much less seriously injured than those not thus resanded.

In regard to the cranberry fruit worm it is stated that late holding of winter flowage appears to be the only method of satisfactorily combating it. Submergence tests show that the fruit worm, in its cocoon, is quite resistant to drowning. The cocoons of this insect are not impervious to water, but the pupæ do not appear to be readily killed by contact insecticides, such as scalecide and blackleaf 40, which were tested during the year. While nearly a dozen

parasites of this worm have been reared, mention of several of which were made in the previous report, only three are abundant enough to be of much importance. It was found during 1914 that the braconid parasite *Phanerotoma tibialis* discussed in the previous report apparently larviposits in the fruit worm eggs. The ichneumonid parasite, previously mentioned, has been determined by Cushman as *Pristomeridia agilis*. The common chalcidid parasite *Trichogramma minuta*, known to parasitize the eggs of not less than 46 other species of insects, is said to be the most important parasite of the fruit worm, 56 per cent of the eggs having been attacked by it on dry bogs in the vicinity of the station bog. The parasitic and predaceous enemies of the fruit worm are said to have destroyed not less than 90 per cent of the infestation on dry bogs and fully 66 per cent on flowed bogs in the vicinity of the station.

The control of citrus insects, H. J. QUAYLE (*California Sta. Circ. 129 (1915), pp. 35, figs. 18*).—A summarized account of the various means for controlling citrus pests.

Control of dried-fruit insects in California, W. B. BARKER (*U. S. Dept. Agr. Bul. 235 (1915), pp. 15, pls. 7, figs. 4*).—This report is based upon work conducted in central California in large part since 1911, at which time it was taken up by the author. The author's summary of the work and conclusions drawn are as follows:

"A considerable financial loss due to the infestation of dried fruit by insects is experienced by packers, wholesale men, and retail dealers. There are several species of insects which attack dried fruits on the Pacific coast, but of these the most common and destructive are the Indian-meal moth and the dried-fruit beetle.

"Infestation takes place in the packing house, in the warehouse, and in the grocery store. The insects find their way to the fruit through small cracks in the boxes and between the folds of the paper. All insect life is destroyed in fruits that are put through the boiling dip, and the processing of other fruits can be accomplished by the addition of the belt heater to sterilize all fruit so treated.

"The use of an insect-free packing room and sterilized cartons or containers which are sealed before being placed in the warehouses or cars will protect the fruit from infestation unless the package is broken. There are several cartons and methods of sealing that can be applied to dried fruit, but their cost will determine their practicability. The secret of preparing an insect-free package of dried fruit is to sterilize it at a temperature of 180° F. and protect it from future infestation by the use of the insect-free packing room and sealing in sterile cartons or packages.

"The sealed carton not only protects the fruit from infestation, but it prevents it from drying out and preserves it for long periods in the moist and attractive condition in which it was packed. Moist fruit can be successfully packed in sealed cartons, provided attention is paid to the moisture content. The fruit must be carefully drained and must not be packed too hot. Machines have been invented which will successfully wrap and seal small packages of dried fruit at a moderate cost per thousand. It is probable that the time is coming when it will be as necessary to put up dried fruit in sealed packages as it is to pack cereals in that form to-day."

Some external parasites of poultry with special reference to Mallophaga, with directions for their control, G. W. HERRICK (*New York Cornell Sta. Bul. 359 (1915), pp. 233-268, figs. 22*).—This bulletin deals in large part with the Mallophaga, or bird lice (pp. 233-251), their injury to fowls, life history, etc. A host list is given of the species reported as found on fowls and brief popular

accounts with illustrations and notes on the occurrence of the more important. Other parasites of fowls briefly considered are the poultry mite (*Dermanyssus gallinae*), the common hen flea (*Ceratophyllus gallinae*), the southern hen flea (*Echidnophaga gallinaceus* seu *Xestopsylla gallinacea*), the harvest mite (*Trombidium* sp.), and a tick that infests turkeys, namely, *Hemaphysalis chordeilis*, which has been found to occur in Warren County, N. Y. The bulletin concludes with a brief account of methods of controlling the parasites of domestic fowls.

A new wheat thrips, E. O. G. KELLY (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 219-224, pl. 1).—It is stated that a new thrips, described by Hood in 1914 from material collected by the author in 1908 as *Prosopothrips cognatus* (E. S. R., 30, p. 658), frequently becomes injurious to wheat (*Triticum* spp.) in localized areas, but has not as yet been discovered to injure other grain crops. This species of thrips is known to occur in all parts of Kansas, even to the western border; in Oklahoma; at two places in western Missouri; and in one locality in extreme southern Nebraska. Careful search has failed to detect it in northern Texas, eastern New Mexico, western Nebraska, and in Kentucky, Tennessee, and Georgia.

The eggs, which are deposited in the tissue of the young leaves of wheat or grass, hatch in from 6 to 10 days. The larvæ become full grown in from 10 to 12 days and crawl down the plants into the soil where they pupate and transform to adults. The pupal period occupies from 10 to 13 days while the newly issued female requires but from 2 to 3 days to prepare for egg laying. A few adults are said to have lived for a period of 8 months in the laboratory. There are from 4 to 5 generations of this species each year which overlap one another so that adults and larvæ are present at all times, even in late winter.

Wheat plants furnish its principal food from the time the volunteer plants sprout in August until the crop is harvested the following June. During the interval between wheat harvest and the sprouting of volunteer wheat the thrips feed and reproduce on *Agropyron smithii*, *Elymus canadense*, *E. virginicus*, *Syntherisma sanguinalis*, *Panicum crus-galli*, and *Hordeum jubatum*, upon which they may also be found at all seasons. The injury by this thrips is confined to the leaves of young plants, unfolding heads and newly formed grains of wheat, and the young unfolding leaves of some grasses. "The leaves when attacked by a dozen or more individuals at one time become badly mutilated in a few hours and, owing to the influence of sunshine and wind, soon acquire a 'rusty' appearance. Since the injured leaves nearly always cover the next unfolding leaf, the injury often becomes disastrous to the plant by preventing the new shoot from developing. The heads are first attacked when in blossom, the pollen being eaten greedily. The tender stamens and pistils are lacerated badly and dry up very quickly, so that the embryo seeds are killed in a kind of injury seldom observed and one wherein the damage can hardly be estimated, although evidently it is considerable. As soon as the grains begin to form, the thrips attack the husk, and later, gaining access to the husk, they lacerate the tender integument of the newly forming grain. Grains attacked at this stage are practically destroyed, and even after the milk has become a dough the injury causes the grains to shrivel."

It is stated that at the present time no thoroughly practical remedy can be offered for the control of this pest, although large numbers may be destroyed by burning off all grasses.

Control of the citrus thrips in California and Arizona, J. R. HORTON (*U. S. Dept. Agr., Farmers' Bul.* 674 (1915), pp. 15, figs. 7).—A popular summary of means of control of the citrus thrips, accounts of which by Jones and Horton have been previously noted (E. S. R., 25, p. 657).

A new species of North American Tingitidæ, O. HEIDEMANN (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 3, pp. 136, 137, fig. 1).—A new species which seems to have a wide range of distribution, from the Atlantic coast to the Southwestern States, having been collected from *Solanum carolinense* and *S. elaeagnifolium* at Kirkwood, Mo.; in Lavaca County and at Columbus, Tex., on coffee weed and *Solanum*; at El Reno Okla.; and at Norfolk, Va., is described as *Gargaphia solani*.

The eggplant lace-bug, D. E. FINK (*U. S. Dept. Agr. Bul.* 239 (1915), pp. 7, pls. 6).—This work is in cooperation with the Virginia Truck Station.

Injury by lace-bugs, which first attracted the author's attention in the vicinity of Norfolk, Va., during the spring and summer of 1913, has been found to be due to a new species that has been described by Heidemann as *Gargaphia solani* (see above). During the spring and summer of 1914 investigations proved it to be widely distributed in Tidewater Virginia wherever eggplant was grown on a commercial scale, and also at Occoquan, Va., in the District of Columbia, and in Maryland.

The work of this pest somewhat resembles that of aphidids. All stages may be found on the underside of the leaves, and in the nymphal stages particularly they always feed in original colonies as hatched. "The first stage of injury appears in the form of circular discolored areas of about the size of a silver quarter. Such a leaf when examined will show a mass of eggs, and usually the female also will be observed either in close proximity feeding or in the act of ovipositing. Upon emergence of the nymphs from the eggs the discoloration of the leaves increases in area until finally the entire leaf is involved, turning yellow and dry. The nymphs migrate from one leaf to another, injuring every leaf attacked, until they transform, after which, as adults, they disperse to other plants. Not every plant in a field will be injured, but once a plant becomes infested every leaf may be so injured as to result in the loss of the plant." While the injury by the lace-bug to eggplant is usually attributed to plant lice, it is entirely well-defined and individual in character and can be readily recognized.

Five nymphal stages have been observed, technical descriptions of which are presented. Adults and eggs were found by the author as early as May 20, the egg-laying period in the field lasting from 4 to 5 days. The author records 116, 117, and 188 eggs, respectively, as deposited by three females kept in confinement. An incubation period of from 5 to 8 days was observed during the last of May, June, and early July. The period required for development of the nymph under normal conditions is said to be about 10 days. Allowing 6 days for the egg stage and several days for time before and after copulation by adults, the life cycle is approximately 20 days. In the vicinity of Norfolk this lace-bug was found breeding as late as November, giving a breeding season of nearly 6 months. Thus there is a possibility of from 7 to 8 generations a season. Apparently 6 generations are spent on eggplant and the remainder on horse nettle.

Several insect predators are recorded as having been observed feeding on the nymphs and adults. Quite satisfactory results were obtained in spraying experiments in the use of fish-oil soap and with a standard blackleaf tobacco extract containing 40 per cent active nicotin sulphate. The percentage of nymphs killed was but slightly affected by the increase in the amount of nicotin sulphate from 1:1,066 up to 1:640; the latter had no effect whatever on the adults. With each increase in the amount of fish-oil soap up to 6 lbs. to 50 gal. of water there was a corresponding increase in the percentage of nymphs killed, and at the latter strength some of the adults were affected. At a strength of 8 lbs. of

fish-oil soap to 50 gal. of water all the nymphs and 95 per cent of the adults were killed.

Leafhoppers of Maine, H. OSBORN (*Maine Sta. Bul.* 238 (1915), pp. 81-160, figs. 25).—This report deals mainly with the leafhoppers proper or Jassoidea which includes the families Tettigoniellidæ, Jassidæ, Bythoscopidæ, and Typhlocybide. It is pointed out that the principal economic importance of leafhoppers is due to their attacks upon oats, timothy, wheat, and other cereal and forage crops, fruits of various kinds, and forest and shade trees. The author here deals with 153 forms, representing 34 genera, of which 12 species are described as new to science. Brief descriptions are given of the species with records of their occurrence in the State.

The species found by the author as being most in evidence in meadows and grasslands in Maine are *Cicadula 6-notata*, *Deltocephalus inimicus*, *D. configuratus*, *Acocephalus striatus*, *Draculacephala mollipes*, *D. angulifera*, and *D. noveboracensis*. The species affecting fruit and garden crops are more commonly noticed, particular mention being made of the damage caused by the grape leafhopper (*Typhlocyba comcs*) and by the apple leafhopper which affects not only apples but quite commonly such crops as potatoes, beans, and other garden crops.

Methods of control are briefly considered under the headings of crop rotation, clean culture, mowing, burning, spraying, and the use of the hopperdozer. Keys to the families of Jassoidea and to the genera of these families are included.

The sharp-headed grain leafhopper, E. H. GIBSON (*U. S. Dept. Agr. Bul.* 254 (1915), pp. 16, fig. 1).—The data here presented are based upon an entire season's work in the Salt River Valley, Arizona, during 1914, together with occasional observations elsewhere. The most extended account of this species previously published is that by Osborn in a bulletin previously noted (*E. S. R.*, 27, p. 858). The present paper, which supplements that account, includes quotations therefrom.

The greatest damage caused by this leafhopper is to young and tender grain crops by the nymphs and adults during the fall and early spring months. The greatest injury to corn and other crops is done during the summer months, while that to alfalfa will probably always be very slight on account of its rapid growth. Ordinarily the feeding of the nymphs is more injurious to a plant than that of the adults, because they are present in greater numbers. Injury is also produced by the adult female by puncturing and constructing pockets in the leaves and stems for oviposition.

This jassid has an extremely wide distribution, ranging from the Atlantic to the Pacific and from the strictly boreal portions of Canada south into Mexico. The author has taken the nymphs and adults in large numbers from wheat, barley, oats, alfalfa, bur clover (*Medicago denticulata*), sour clover (*Melilotus indica*), Johnson grass (*Sorghum halepense*), wall barley (*Hordeum murinum*), and many other native grasses of the South and Southwest.

Five nymphal instars have been observed, descriptions of which are presented. The incubation period of the egg in southern Arizona was found to vary from 3 to 35 days, with an average of 12 days. Observations at Tempe, Ariz., show the length of the nymphal stage to vary from 20 to 51 days. While Osborn has stated that hibernation seems to occur in all stages from egg to adult, although the great majority must pass the winter in the egg stage, the author has as yet failed to find other than the adult stage to do so. He concludes that it is safe to assume that the species winters over principally in the adult stage throughout the Southern States, and that in all probability the same holds true throughout the country.

Egg parasites are said to be the most effective enemies, two new species of which were reared by the author during the summer of 1914, one described by Crawford as *Gonatocerus gibsoni* (see above) and the other to be described by Girault as *Abbella auriscutellum*. *G. gibsoni* is said to have not only held the pest in check but to have practically eradicated it in the Salt River Valley during the summer of 1914, from 75 to 95 per cent of parasitism having been observed between May 15 and June 15. Two egg parasites were reared in considerable numbers by Ainslie in Florida during the spring of 1914, one of which has been determined as *Brachistella acuminata*.

As regards remedial measures it is stated that in localities with conditions similar to those in Salt River Valley, Arizona, much can be accomplished through the keeping down of wild grasses, principally Johnson grass, along irrigation ditch banks, fence rows, and along roadsides during the summer months. As soon as possible after the grain is harvested the ground should be broken up and planted. Where the species infests pastures or grass lands close pasturing or cutting while it is in the egg stage is advised. It is thought that in the Northern States the burning of grasses in which the species may be hibernating will destroy many of the adults.

Influence of soil moisture upon the rate of increase in sugar-beet root louse colonies, J. R. PARKER (*U. S. Dept. Agr., Jour. Agr. Research*, 4 (1915), No. 3, pp. 241-250).—During the course of studies of the sugar-beet root louse (*Pemphigus betæ*) at the Montana Station, an account of the life history of which species has been previously noted (*E. S. R.*, 31, p. 250), it was found that soil moisture is a very important factor in the control of the rate of increase in root-louse colonies. In the present paper the author reports upon general field observations, insectary experiments, and field irrigation tests of the effect of soil moisture. In irrigation experiments at Huntley, Bozeman, and Edgar, it was found that sugar beets grown under rather moist conditions were the least infested with root lice and yielded the highest in both sugar content and in tonnage. By irrigating early before the fields become dry the chances of root louse infestation are reduced and the best conditions for plant growth are secured.

The Hessian fly, T. J. HEADLEE (*New Jersey Stat. Circ.* 46, pp. 3-8).—A brief popular account of this pest and means of control, including a table for determining the date of safe sowing at different altitudes and latitudes in the State.

Fly baits, J. E. BUCK (*Alabama Col. Sta. Circ.* 32 (1915), pp. 34-39, fig. 1).—This is a brief report of work at the station barns during the summer and fall of 1914, during the course of which more than 50 tests were made with a view to determining the relative attractiveness to flies of various baits used in wire traps. The baits were exposed from 2 to 5 hours in a test and from 2 to 18 hours in a series.

In all tests the baits were exposed 138 hours, catching a total of 104,041 flies. Formulas are given of twelve of the most important baits in the order of their attractiveness, all of which are said to have been thoroughly tested in comparison with each other and with still others, and can be relied upon for good results. The one first mentioned is that of light bread, buttermilk (to which 7 per cent of 40 per cent commercial formaldehyde has been added), and a little sugar or sirup.

Control of the onion fly, J. G. SANDERS (*Country Gent.*, 80 (1915), No. 12, pp. 572, 573, figs. 5).—Following studies of the life history of the onion maggot (*Pegomya cepetorum*) at the University of Wisconsin by C. R. Cleveland and H. H. Severin, showing a period of from 10 to 14 days between the emergence

of the adult fly and the beginning of oviposition, control experiments were conducted to determine whether the adults could be poisoned during the interim, as previously noted (E. S. R., 31, p. 849).

It has been found that sodium arsenate at the rate of $\frac{1}{2}$ oz. to a gallon of boiling water to which 1 pint of New Orleans molasses is later added furnishes a spray that is cheap, attractive to the pests, and effective. "In actual practice it has been found that a field may be treated in checkerboard fashion or in alternate strips, leaving an untreated strip of a width similar to the treated areas, since the flies are strongly attracted to the poison bait spray when freshly applied. The frequency of treatment is most important. During fair weather the application of this poison bait once a week regularly is sufficient, but in rainy weather it is desirable to apply it at least twice a week, especially if a shower follows the application. It is urged that the poison bait spray be also applied to weeds or other vegetation adjoining the onion fields to poison any individual flies that may be resting at these locations." It is stated that a number of onion growers in Wisconsin tried out this poison bait spray during the summer of 1914 under actual field conditions and harvested almost perfect stands, and the best crop grown in fifteen or more years.

Insecticides for the control of the Colorado potato beetle (*Leptinotarsa decemlineata*), L. B. SMITH (*Virginia Truck Sta. Bul. 14 (1915), pp. 315-333, figs. 5*).—This is a general summary of the results of field work on the control of the Colorado potato beetle conducted in Tidewater Virginia, during the season of 1914. The results indicate that for the farmer who grows 5 acres or more of potatoes Bordeaux mixture (4:6:50), together with arsenate of lead paste from 4 to 6 lbs., and 1 lb. of Paris green to 50 gal. of mixture has not yet been surpassed as a spray for potatoes by any of the proprietary insecticides now in use either from the standpoint of efficiency or economy. It is thought that the most economical and efficient results in spraying under Tidewater conditions may be obtained through the application of Paris green and lime dust when the first green shoots are showing, followed as soon as the plants are from 4 to 8 in. high by some liquid spray, preferably that above mentioned. This should be applied at least every 10 days and the application repeated preferably once a week until the crop is ready for harvest. A description of a Bordeaux mixing plant is included.

The southern corn leaf-beetle, E. O. G. KELLY (*U. S. Dept. Agr. Bul. 221 (1915), pp. 11, pls. 2, figs. 6*).—During the last few years the southern corn leaf-beetle (*Myochrous denticollis*) has become a pest of considerable importance. It first came to the author's attention in the bottom lands of the Ohio River in southern Illinois in 1905, and has since been observed by him in Kansas, northern Texas, and eastern Arkansas. These observations and others by Webster in Louisiana and Ohio^a seem to indicate that it occurs in destructive abundance on lands that have previously been devoted to pasture or on lands which have been allowed to lapse into a semiwild condition, not having been cultivated for several years. The species is widely distributed over the southern half of the United States, extending from the extreme southeastern part of Arizona to southern Texas, becoming more numerous directly north of Brownsville, thence northward to southern Iowa, and eastward to northern Illinois and central Ohio and to Washington, D. C., the most southeastern point recorded being in northern Florida.

While numbers of larvæ have from time to time been found in the soil, always in close proximity to corn roots which were more or less eaten, in no

^a Jour. N. Y. Ent. Soc., 9 (1901), No. 3, pp. 127-132.

instance have they actually been observed feeding on corn roots, although special attention has been given to their feeding habits.

In the laboratory the eggs hatch in from 6 to 10 days, but the larvæ have not as yet been reared to maturity, notwithstanding repeated attempts to do so. In numerous searches made in cornfields, wheat fields, grass, and fields grown up with weeds, the larvæ have not as yet been found feeding on plants other than corn. The first larvæ found in the field were observed at Wellington, Kans., July 20, 1910, in small, round earthen cells from 4 to 6 in. deep, with a small burrow leading toward the corn roots which had been more or less eaten. Very few larvæ or pupæ have been found in sandy or light soils, and correspondingly few injured corn roots have been observed.

Laboratory records made at Brownsville, Tex., by Vickery indicate that the larval period extends from about April 1 to June 15, while the author's observations at Plano, Tex., show the larval period to range from April 15 to July 1, and at Wellington, Kans., from May 1 to July 15. "In the bottom lands of the Arkansas River, near Paris, Ark., the larvæ had pupated and practically all the adults had issued by July 22, 1914, indicating that they began pupating as early as July 1. In the vicinity of Wellington, Kans., the larvæ began to pupate about the middle of July, pupæ being found as early as July 20 and as late as August 14. The period for maturing the pupa seems to be about 15 days, although no exact data have been obtained. The first pupæ to be found were in earthen cells in the soil near corn plants at depths of from 4 to 6 in."

Because of the fact that the adults have the habit of dropping from their food plants to the ground and hiding when disturbed, they are very rarely seen. The beetles seem to prefer feeding early in the morning, late in the evening, or at night, or on cloudy days. The adults issue from pupal cells about the middle of July in central Arkansas and the first of August in southern Kansas, emergence extending over a period of about one month. They do considerable feeding on the kernels of unripe ears of corn and buds of cocklebur before entering hibernation, which begins early in the fall. Corn is the only cultivated crop that has been found to be attacked in sufficient numbers to cause serious damage, but the beetles have been observed to attack the young leaves and growing shoots of cocklebur, smartweed, Japan clover, and crab grass. They have also been observed to feed upon sorghum, *Alopecurus geniculatus*, cotton, and alfalfa, but on the latter plant only in rearing cages in the laboratory.

In regard to remedial measures it is stated that a great number of beetles have been collected at lights, indicating that a powerful light trap located in the vicinity of the infested field might materially reduce them, especially in the early fall when they are flying in search of hibernating quarters. It is suggested that the cleaning up of all rubbish in the cornfield early in the fall, especially in fields of very late corn, will prove an effective remedy in the protection of succeeding crops. No remedy has been found that can be recommended in combating them after they once enter the cornfield. If a crop is so badly damaged as to be worthless it can be replanted with safety from damage by this insect about one month after the regular planting time, since within a few days after the leaf-beetles have killed out the first planting they will leave the field. It is thought that something might be gained by delaying corn planting in localities where beetles have been injurious the previous year. Experimental work by Gibson in the vicinity of Charleston, Mo., during late April and early May indicates that the beetles can be readily destroyed by a poison bran bait, consisting of 25 lbs. of wheat bran, 1 lb. of Paris green, 1 gal. of low-grade molasses, and the juice of 3 oranges, with enough water to bring the mixture to a stiff dough.

A list of 8 references is included.

Contributions toward a classification and biology of the North American Cerambycidae.—Larvæ of the Prioninae, F. C. CRAIGHEAD (*U. S. Dept. Agr. Rpt. 107 (1915), pp. 24, pls. 8*).—The present paper is based upon rearings for identification of some 200 species additional to some 50 on which the report by Webb (*E. S. R., 27, p. 756*) was based. Emphasis is made of the need of great care in rearing these larvæ, it being stated that a single piece of infested wood may contain from five to a dozen different species of Cerambycidae.

The larvæ of this family of beetles are primarily and probably without exception phytophagous, boring in the ligneous tissue of, for the most part, the aborescent flora, though a few species are confined to herbaceous plants, in this case being usually pith or root feeders. Some are confined to one species of tree, as is usually the case with those attacking living tissue, others to a single genus, and again there are species which will have a wide variety of host plants among either the conifers or the hardwoods, but the larvæ of the same species will rarely attack both indiscriminately.

Keys to the larvæ of the subfamilies of Cerambycidae and to the genera of the Prioninae, and general anatomical characteristics and descriptions of larvæ of Prioninae are given.

The roundheaded apple-tree borer, F. E. BROOKS (*U. S. Dept. Agr., Farmers' Bul. 675 (1915), pp. 20, figs. 19*).—A popular summary of this pest, its life history and habits, natural enemies, and methods of control.

Some sugar-cane root-boring weevils of the West Indies, W. D. PIERCE (*U. S. Dept. Agr., Jour. Agr. Research, 4 (1915), No. 3, pp. 255-263, pls. 4*).—The present paper, which deals with the weevils of the genus *Diaprepes* that attack sugar cane in the West Indies, has been prepared with a view to straightening out the difficult nomenclature, to point out the dangerous nature of the injury by the species treated, and so to describe the various forms that quarantine agents may readily detect them. The author calls attention to the fact that, due to their variable color, shape, and markings, it is extremely difficult to determine their specific limitations. Two species, namely, *Diaprepes spengleri* and its six varieties (*marginatus, comma, spengleri, abbreviatus, denudatus, and festivus*), and *D. famelicus* are recognized and here considered, one of which varieties (*D. spengleri denudatus*) from Guadeloupe is described for the first time.

Descriptions of new Hymenoptera, IX, J. C. CRAWFORD (*Proc. U. S. Nat. Mus., 48 (1915), pp. 577-586, figs. 11*).—Among the new species here described, of economic importance, are the following: *Hexaplasta marlatti* reared at Warrenton, Va., from cow dung with *Hæmatobia*; *H. fungicola* reared from dipterous larvæ in mushrooms at Washington, D. C.; *H. websteri* reared from *Euxesta nitidiventris* at Wellington, Kans.; *Figites popenoei* reared from *Boletus bicolor* at Washington, D. C.; *Zelotypa fungicola* reared from dipterous larvæ in *B. felleus* at Clarendon, Va.; *Geniocerus chrysopæ* reared from cocoons of *Chrysopa* at Batesburg, S. C.; *G. juniperi* and *G. marcovitchi* reared from berries of *Juniperus virginiana* at Ithaca, N. Y.; and *Gonatocerus gibsoni* reared from the eggs of *Draculacephala mollipcs* at Tempe, Ariz.

FOODS—HUMAN NUTRITION.

[Food and drug topics], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul., 3 (1915), No. 17, pp. 289-304*).—This bulletin, which gives information regarding some proprietary medicines, including a so-called hog-cholera remedy noted on page 359, contains a report, by R. O. Baird, of the chemical analysis of 29 samples of molasses.

A report, by T. Sanderson, on a comparison of the values of four types of hard red spring wheat, namely, Marquis, Velvet Chaff, Bluestem, and Fife, in co-operation with the Office of Grain Standardization of the U. S. Department of Agriculture, completes the bulletin. From the results of milling and baking tests carried out with these varieties and previous work (E. S. R., 30, p. 666), the following conclusions, among others, are drawn:

"From the data at hand Marquis has done better this year than last, compared with the other types, and is clearly in the lead, Bluestem second, Fife third, Velvet Chaff fourth, when considered from value of products.

"We are not in a position to advocate the growing of any one of these types of wheat over the other, because of the wide variation of soil and climatic conditions which we believe the farmer to be familiar with in his own locality, and should be governed by, in the selection of the type of wheat to grow.

"In view of the discrimination against the Velvet Chaff, we feel constrained to advise the farmers to discontinue its production as far as possible, substituting any one of the other three that has been doing well in their locality."

The digestibility of the proteins of cereals, legumes, and potato flour, O. RAMMSTEDT (*Pharm. Zentralhalle*, 56 (1915), Nos. 1, pp. 1-7; 2, pp. 14-17; 3, pp. 22-25).—In this digest of data the author brings together information regarding the relative nutritive value of corn, wheat, potatoes, and legumes prepared and cooked in different ways. The use of corn, peas, lentils, and beans is recommended as a substitute for meat and wheat flour in times of food stringency.

The influence of the environment on the milling and baking qualities of wheat in India.—III, The experiments of 1911-12, A. HOWARD, H. M. LEAKE, and GABRIELLE L. C. HOWARD (*Mem. Dept. Agr. India, Bot. Ser.*, 6 (1914), No. 8, pp. 233-266, pls. 2).—The work here reported is a continuation of that previously noted (E. S. R., 29, p. 263). The experiments were carried out to determine whether a good grade of wheat produced in only a limited area could be successfully cultivated in other sections of India under a different environment. A standard variety of wheat was grown at a number of different stations and samples compared as regards consistency, absolute weight, nitrogen content, and milling and baking qualities. The results of these tests indicated that the environmental conditions of different sections of India were not sufficiently unfavorable to influence seriously the strength and milling qualities of good wheat.

Banana meal a substitute for flour, J. C. MONAGHAN (*U. S. Dept. Com., Com. Rpts.*, No. 129 (1915), p. 1019).—This article notes the combination of banana meal with wheat flour for bread making in Jamaica.

Digestive disturbances following the use of war bread, and their treatment, C. VON NOORDEN (*Berlin. Klin. Wehnschr.*, 52 (1915), No. 14, pp. 349, 350).—Clinical observations are reported which tend to show that the excessive use of rye-potato bread produced disturbances in the digestive tract, especially fermentation, dyspepsia, hyperacidity of the stomach, and excessive gas formation.

Bread seasoning, A. MAURIZIO (*Naturw. Wehnschr.*, 30 (1915), No. 15, pp. 225-228).—A summary and digest of data in which is described the custom of seasoning bread as practiced at different times in this and in other countries. It is pointed out that the use of most spices and flavors is governed either by necessity or by long-continued usage.

Proso and kaoliang as table foods (*South Dakota Sta. Bul.* 158 (1915), pp. 147-176, figs. 2).—General information is given by N. E. Hansen regarding the history, cultivation, and milling of different varieties of these grains, including analyses. The publication also contains the results of an investigation of their

use as food by Nola K. Fromme. It is stated that while proso is practically unused in America as a food, in Russia and India it has been so used for some time. The grain may be used whole, ground into a meal, or finely ground into flour. A number of recipes and suggestions for its use in cooking are given. Information is also given regarding the use of kaoliang as food, it being compared with grain sorghums. A number of recipes are given, in some of which kaoliang is used in the same way as corn meal or Kafir corn flour.

The nutritive value of the avocado, M. E. JAFFA (*California Sta. Bul.* 254 (1915), pp. 395-402, figs. 2).—This paper reports the results of the chemical analysis of 28 varieties of the avocado. The approximate composition of the edible portion, constituting 65.7 per cent of the fruit, is as follows: Water, 69.16 per cent; protein, 2.08 per cent; fat 20.1 per cent; carbohydrate, 7.39 per cent; and ash, 1.26 per cent. The average energy value found was 984 calories per pound, or more than twice the maximum noted for any other fruit. The amounts of protein and ash found were greater and the amount of carbohydrate about one-half that found in most fresh fruit. The value of the avocado as food is chiefly due to its high fat content, which is greater than that of the average olive. It is assumed that the avocado is quite thoroughly digestible.

Unfermented grape juice, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul.* 307 (1915), pp. 19).—This bulletin contains data regarding the inspection of 111 samples of unfermented grape juice collected in various parts of Canada. The legal requirements for grape juice are also given.

The preservation of meat, H. COPAUX and A. KLING (*Génie Civil*, 66 (1915), Nos. 14, pp. 209-214, figs. 14; 15, pp. 227-230, figs. 3).—In this article, which describes somewhat in detail the process of the manufacture of canned meats for an army camp, the Appert and Billancourt processes are considered. Special attention is given to the methods of preparing meat and the mechanical processes involved in packing it for shipment.

Bacterial content of desiccated egg, L. S. ROSS (*Proc. Iowa Acad. Sci.*, 21 (1914), pp. 33-49).—The results are reported of a bacteriological examination of 66 samples of liquid egg yolk and 76 samples of liquid egg white, as well as 248 samples of desiccated eggs which had been stored for varying lengths of time at different temperatures. The author concludes as follows:

“The desiccated egg loses a large percentage of the bacteria originally present if stored for even a relatively short period. Also the experiment indicates a more rapid diminution if storage is at a higher temperature than at a lower. And it seems possible that a poor product, even one prepared from ‘spots’ and worse, might satisfy the ordinary bacterial test of colony counting and gas determination after a period of a few months’ storage.”

Cooking fats in South America (*U. S. Dept. Com., Spec. Cons. Rpts.*, No. 67 (1915), pp. 15).—This publication contains information regarding the use of various cooking fats in the different countries of South America. Data are given regarding the quantity and value of such fats imported by the different countries in the years 1912 and 1913 and six months of 1914.

The use of hardened fats for food purposes, H. THOMS and F. MÜLLER (*Arch. Hyg.*, 84 (1915), No. 1, pp. 54-77).—The authors report a number of chemical and physiological tests of peanut, sesame, and cotton-seed oil.

In long-continued animal feeding experiments and in tests of one week's duration with men, the availability of the hardened vegetable oils was compared with that of some of the more common animal fats and also with the same vegetable oils in the fluid condition. As a result of this work it is recommended that a fat should not be hardened to give a melting point of over 37° (body temperature). It was found that, in practically every case, if the digestibility of fats melting higher than this was not noticeably different from that of

lower melting fats, a tallowy taste and intestinal and other passing disturbances, such as are usually noticed with beef and mutton tallow, were experienced. Should the melting point be higher than 37° , it is suggested that a suitable mixture may be prepared by the addition of a lower melting fat.

Use of hydrogenized fish oil in the manufacture of oleomargarin. J. KLIMONT and K. MAYER (*Ztschr. Angew. Chem.*, 27 (1914), No. 96-97, *Aufsatzteil*, pp. 645-648; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 3, p. 148).—As objections to the use of this product it is noted that on account of improper control of the production of crude oil, its disagreeable odor may appear if the hydrogenized oil is kept for some time. The hydrogenized oil may also contain small quantities of nickel and has a higher melting point than any of the fats commonly used for food.

A description is given of a method for detecting the presence of hardened fish oil in oleomargarin.

Nineteenth report on food products and seventh report on drug products, 1914. J. P. STREET (*Connecticut State Sta. Rpt. 1914*, pt. 5, pp. 227-356).—The first part of this report contains the detailed results of the examination of a number of samples of food products, showing the net weight, cost, and calculated energy value per 100 gm. in addition to the chemical composition of the food products.

Eighty-eight samples of biscuits and crackers were examined, including graham, oatmeal, ginger, cheese, and whole-wheat crackers and others of miscellaneous character. Regarding these products the author states that "many of these are more strictly confections than foods, and this must be kept in mind in connection with their high cost. From the food standpoint many of them the consumer would not be justified in purchasing; on the other hand, judged as confections, their daintiness, tastiness, general attractiveness, and cleanliness might justify such high prices as from 60 cts. to \$1.50 per pound. Furthermore, it is only just to say that in many cases the biscuits may be bought in bulk as well as in small packages, thus permitting a considerable saving in cost, with a possible loss as to freshness and cleanliness."

Examinations were also made of 12 samples of bran biscuits and laxative preparations, and 2 samples of condensed soups. In continuation of earlier work (E. S. R., 29, p. 660), 72 samples of diabetic foods were analyzed. Tabular data regarding these are also contained in the report.

The second part of this report contains the results of the examination of several samples of drug products, including toilet preparations and proprietary medicines. Detailed information is given regarding each of 130 samples of proprietary medicines analyzed. The author states that of these "35 might be passed as possessing some merit, but even these are expensive; they are generally toilet preparations and in certain cases possibly the convenience of their use might justify their purchase even at the high prices."

A general review of the effect of food inspection in Connecticut since 1895 is appended.

Twenty-first annual report of the Dairy and Food Commissioner of the State of Michigan (*Ann. Rpt. Dairy and Food Comr. Mich.*, 21 (1914), pp. 458+[3], pls. 2, figs. 20).—The inspection and educational work carried on under the state food and drugs laws during the year ended June 30, 1914, is reviewed.

The report of the state analyst, F. L. Shannon, gives detailed information regarding the analysis of 1,719 samples of food products, of which 717 were found to be adulterated or misbranded. The report of the drug analyst, A. R. Todd, gives the results of the examination of 571 samples, of which 214 were

condemned as not conforming to the requirements of existing standards. Inspections were made of 17,318 grocery stores, hotels, restaurants, bakeries, dairies, creameries, cheese factories, and other establishments where food was handled or manufactured.

The educational work consisted in speaking before various organizations, in disseminating popular information through pamphlets or bulletins, a number of which are reprinted in the report, and in the preparation of pure-food exhibits.

In this publication is also included the first annual report of the work done by the state sealer of weights and measures. This includes specifications for various food containers, as well as for weights and measures.

A review of the prosecutions and decisions relative to the inspection and adulteration of foods completes the report.

The Food and Drugs Act (*U. S. Dept. Agr., Office Solicitor Circ. 82 (1915), pp. 5*).—According to the decision of the U. S. Circuit Court of Appeals for the First Circuit, here reported, confectionery containing talc is held to be adulterated within the meaning of the Food and Drugs Act, although the amount of talc contained is a mere trace.

Food—what it is and does, EDITH GREER (*Boston: Ginn & Co., 1915, pp. VII+251, pls. 8, figs. 92*).—This book is intended as a school text-book and summarizes the characteristics of animal and vegetable foods, their methods of production, place in the diet, and the hygiene of their use. It includes charts, tables of composition, statistics of production, and many illustrations, some of the latter chiefly decorative in value.

Physics of the household, C. J. LYNDE (*New York: The Macmillan Company, 1914, pp. XI+313 figs. 217*).—This publication differs from most elementary text-books in that illustrative examples are taken largely from the household and for this reason should be of interest to teachers of physics in schools offering courses in home economics. The principles of physics involved in many common household processes are fully explained. Chapters are devoted to heat in the home, including a study of different kinds of heating and cooking appliances, heat measurement, etc. Other chapters devoted to the use of electricity in the home discuss heating, cooking, and lighting and other electrical appliances.

[**Popular nutrition bulletins**] (*Bul. Univ. Tex., 1914, Nos. 333, pp. 20; 342, pp. 20; 344, pp. 12; 345, pp. 12; 347, pp. 19; 350, pp. 13; 366, pp. 20*).—This series contains a number of popular bulletins, among which are the following, which would be of interest to housekeepers or to those engaged in extension work in home economics: *The Principles of Menu Making*, by Anna E. Richardson; *Food for Growing Children*, *Cooking Tough Meats*, and *The Uses of Foods and the Proper Balancing of the Diet*, by Jessie P. Rich; *Meat, Its Value as Food, and Its Proper Preparation*, prepared by the Division of Home Welfare; and *The Irish Potato*, and *Nuts and Their Uses as Food*, by Jessie P. Rich.

The public feeding of elementary school children, PHYLLIS D. WINDER (*New York: Longmans, Green, & Co., 1913, pp. VII+84*).—This report, which is one of the series entitled *Birmingham Studies in Social Economics and Adjacent Fields*, edited by W. J. Ashley, reviews and criticizes the methods and results of school feeding in Birmingham, England. The aspects of the subject here considered are some of the causes of malnutrition, the methods employed for selecting the children as compared with those generally used, the time and nature of the meal, the service and its supervision, the family circumstances of the children, and the effect of the meals on the child and on the family. Among the factors given as the cause of malnutrition are poverty, unsuitable

and ill-cooked foods, insufficient sleep, poor ventilation, and general insanitary surroundings.

Experience showed that it was desirable to supply in the meals those food constituents in which the customary home diet was deficient, viz, protein and fat.

Where breakfast was the meal served, porridge was found to be one of the best foods, it being served with treacle or sugar and milk, and followed by bread and "dripping." Where dinner was provided a number of menus were used, consisting of fish, meat pies, vegetable dishes, stews, roast meats, stewed fruits, milk suet puddings, and the usual soup.

In the appendix are given some typical menus and several examples of family conditions existing in the cases of the children fed. A preface by N. Chamberlain and a bibliography are included in the publication.

A standard dietary for an orphanage, ADELE S. JAFFA ([*Sacramento, Cal.*]: *State Printing Office, 1914*, pp. 28).—This publication gives standard dietaries for children from 8 to 12 years old, for alternate weeks in the month, as well as a few extra menus for variety.

Feeding men in camps, W. FISHER ([*Memphis, Tenn.*: *R. H. & G. A. McWilliams, 1915*], pp. 20).—This pamphlet, issued by a contracting firm for the use of its superintendents, contains specific information for the feeding of laborers in camps. The different foods and amounts of foods to be purchased are listed, and data regarding frequency of service and the size of the portion allotted to each man are given. The appendix contains standard bills of fare for logging camps and the standard garrison ration of the United States Army.

A modern small-sized construction camp with some costs on feeding men, E. W. ROBINSON (*Engin. and Contract.*, 43 (1915), No. 14, pp. 318-320, fig. 1).—This article gives detailed information concerning the plan of the camp, construction of the necessary buildings, and the methods employed in maintaining the camp. Figures are reproduced which show the cost of foods and other supplies used, as well as the expenditure for camp equipment.

Campaign rations for the army, J. BASSET (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 12, pp. 375-378).—Four new rations are described and recipes given for their preparation. Beef or pork forms the basis of these rations, dried fats and dried vegetables being added in sufficient quantity to secure a balance.

Beri-beri, E. B. VEDDER (*New York: William Wood & Co., 1913*, pp. VIII+427, pls. 6, figs. 51).—In this comprehensive treatise of beri-beri its history, distribution, prevalence, pathology, symptomology, and etiology are considered. Under the last-named subject the author takes up at considerable length the questions as to whether it is a specific disease, an intoxication, an infection, or is due to the deficiency of the diet in certain essential principles. One chapter deals with rice and its preparation for the table. Experimental polyneuritis and beri-beri in animals are discussed and considered in their relation to the etiology of the disease in man. Chapters are also devoted to infantile beri-beri, ship beri-beri, and epidemic dropsy.

The publication contains a 54-page bibliography. In the appendix are given in more detail some of the data cited in the book.

Studies on beri-beri.—VIII, The relationship of beri-beri to glands of internal secretion, C. FUNK and M. DOUGLAS (*Jour. Physiol.*, 47 (1914), No. 6, pp. 475-478).—The results are reported of an extended study of the pathological changes observed in the glands of internal secretions of pigeons suffering from experimental beri-beri resulting from an excessive diet of polished rice.

The harmlessness of vinegar eels in the human and animal organism, H. WÜSTENFELD (*Deut. Essigindus.*, 19 (1915), No. 11, pp. 53, 54).—According to the experiments here reported a large number of vinegar eels were ingested without producing intestinal physiological disturbances.

The metabolism of white races living in the Tropics.—I, Protein metabolism, W. J. YOUNG (*Ann. Trop. Med. and Par.*, 9 (1915), No. 1, pp. 91-108).—To determine whether tissue metabolism takes place to a greater extent in a tropical country than in a temperate climate a number of measurements were made of excretory nitrogen and sulfur catabolized by white men living in Queensland, Australia. No considerable variation is reported from the averages obtained in temperate climates, except that the excretion of neutral sulphur was consistently high.

Gastro-intestinal studies.—VII, The utilization of ingested protein as influenced by undermastication (bolting) and overmastication (Fletcherizing), L. F. FOSTER and P. B. HAWK (*Jour. Amer. Chem. Soc.*, 37 (1915), No. 5, pp. 1347-1361).—In this investigation was studied the effect of different degrees of mastication upon the utilization of a typical protein. The subjects of experiment (two young men) were fed a uniform diet, the principal ingredients of which were beef, graham crackers, and milk. The beef, which furnished the major portion of the protein, was cooked in the form of 15-mm. cubes.

The experiment was divided into four 7-day periods, as follows: Preliminary normal, during which the food was masticated normally; bolting, in which the meat was swallowed with no attempt at mastication; Fletcherizing, when the food was chewed until carried down the esophagus by the "swallowing impulse"; and, final normal, in which ordinary mastication was practiced. A nitrogen-free diet was fed through a 4-day period at the close of the experiment proper. The results may be briefly summarized as follows:

"The output of fecal nitrogen was highest during the food bolting; that during Fletcherism was lowest. Protein utilization was most complete as the result of Fletcherism, and least complete when bolting was practiced. The discrepancies, however, averaged only 1.6 per cent. Utilization during Fletcherism averaged 0.17 per cent higher than during normal mastication.

"During food bolting macroscopic meat residues appeared in every stool. In a single stool the amount was 16.5 gm.

"The fineness of the protein may determine the amount of its hydrolytic cleavage. This fact was shown by the higher nitrogen content of the urine in the Fletcherizing period and the lowered output during bolting."

The authors mention that "the fact that pepsin may be absorbed in the stomach by particles of undigested food and carried into the small intestines to aid further in protein hydrolysis may have an important bearing on the question of the digestion of bolted meat."

The conclusion is drawn that "the results of this investigation fail to demonstrate the advantages of Fletcherism or the harmfulness of food bolting. . . Fletcherism of starchy foods should be encouraged to insure the salivary digestion of a large quantity of material."

The circulation of the blood in man at high altitudes.—II, The rate of blood flow and the influence of oxygen on the pulse rate and blood flow, E. C. SCHNEIDER and D. L. SISCO (*Amer. Jour. Physiol.*, 34 (1914), No. 1, pp. 29-47).—From observations of pulse rate and blood pressures of six subjects at high altitudes the following conclusions are drawn, in part: The pulse rate does not accelerate immediately on arrival at an altitude of 14,109 ft., but requires several days to reach its maximum. In the majority of healthy men the arterial pressures are unchanged. In five out of six subjects on Pikes Peak the venous pressure was lowered from 25 to 87 per cent. In consequence of these changes

conditions of the vascular system favor an increased rate of blood flow on Pikes Peak.

Some metabolic influences of bathing in the Great Salt Lake, HELEN I. and H. A. MATTILL (*Amer. Jour. Physiol.*, 36 (1915), No. 4, pp. 488-500, fig. 1).—Observations upon two subjects indicated that bathing exerts a stimulating effect on metabolism. The excretion of chlorids and total nitrogen was materially increased during the bathing periods.

Healthy atmosphere, L. HILL (*Nature [London]*, 95 (1915), No. 2373 pp. 205-207, figs. 3).—In this article, which emphasizes the importance of the rate of cooling the body to comfort and health, two pieces of apparatus are described. These consist of a wet and dry katathermometer by means of which can be measured the rate of heat loss by radiation, convection, and evaporation, as well as the vapor pressure of the atmosphere, and a calorimeter, which automatically indicates the amount of heat energy required to maintain a coil of wire at body temperature and thus shows the cooling effect of air currents.

ANIMAL PRODUCTION.

Influence on growth of rations restricted to the corn or wheat grain, E. B. HART and E. V. MCCOLLUM (*Jour. Biol. Chem.*, 19 (1914), No. 3, pp. 373-395, pl. 1, figs. 11).—A continuation of work previously noted (*E. S. R.*, 26, p. 467; 33, p. 69).

In these studies the authors found that "when swine are restricted to corn meal and gluten feed little or no growth can be secured, but with an addition of salts, making the entire ash content of the ration very similar in quality to that of milk, growth approximating that of a normal curve was secured to at least 275 lbs. These results are not in harmony with the theory that the failure of swine to grow on corn alone is due entirely to the incomplete nature of its protein content. Restriction to mixed grains and distilled water did not allow normal growth with swine. This emphasizes again the very great importance of either the mineral side of a ration, or as yet unknown factors operative in the normal environment of this species, namely, soil rooting, natural water, etc.

"When the wheat kernel supplied all the nutrients, growth was again limited with both swine and rats. However, when the salt content was modified to resemble milk some growth could be secured, but ultimately this ceased, followed by partial paralysis, particularly in swine, and a general decline. Correcting the mineral content of the wheat kernel alone induces a certain amount of growth, but the benefit is only temporary. When the wheat kernel was fortified with salts and butter fat, the growth curve was very much improved in both species, although a normal curve was not secured. The animals, however, remained vigorous and strong for a very much longer period, although partial decline in some individuals, mainly characterized by stiffness, ultimately set in. However, when the wheat kernel, salt, and butter fat ration was supplemented with casein to the extent of 2.5 per cent of the ration, a normal curve of growth was secured for swine. Similar results were secured with rats. Rations may contain as much as 80 to 90 per cent of wheat without bad effects when supplemented with milk or egg yolk. Normal reproduction as well as normal growth have been secured with such rations."

Value of proteins from different sources (*Wisconsin Sta. Bul.* 250 (1915), pp. 49-52, figs. 2).—The data reported are included in the article noted above.

Effect of rations from single plant sources (*Wisconsin Sta. Bul.* 250 (1915), pp. 48, 49).—The studies to determine the physiological effect of rations from single plant sources are briefly noted, those with calves and swine being abstracted above.

In a study with poultry extending over three years, pens of 12 pullets each, as near the same age as possible and of the same breeding, were fed rations restricted to corn, wheat, oats, or barley for 10 months. No appreciable difference was observed during the first 90 days, but when the feeding was continued longer physiological disturbances began to appear on the wheat-fed lots, and at the end of the trial only four, three, and six pullets, respectively, were alive out of the original 12 in each of the three pens. No fowls were lost in the corn lot, and the oats and barley rations ranked midway between the corn and wheat. There appeared to be no consistent difference in the number of eggs produced by the different lots, nor in the percentage or vigor of chicks hatched from the various lots.

Acidosis in omnivora and herbivora and its relation to protein storage, H. STEENBOCK, V. E. NELSON, and E. B. HART (*Jour. Biol. Chem.*, 19 (1914), No. 3, pp. 399-419).—The experiments reported in this paper deal with the rise and fall of urinary ammonia production when swine, as representatives of omnivora, are confined to grains alone or grains supplemented with basic materials. Other experiments deal with the influence of acid rations on ammonia production in herbivora (calves).

It was found that "acid rations fed to swine (omnivora) or calves (herbivora) occasion a rise in urinary ammonia with a compensative fall in output of urea. Presumably on a normal level of protein intake a part of the ammonia, produced either in the intestine or liver, combines with acids and is excreted as the salts of these acids. This power to help maintain neutrality by the production or use of ammonia is apparently very general in all mammals. Ammonia production, under conditions of exogenous protein metabolism, does not occasion an increased nitrogen excretion or an interference with protein storage.

"In herbivora (calves) approximate endogenous nitrogen metabolism, accompanied by mineral acid ingestion, likewise occasions a rise in urinary ammonia, but does not, on the level of acid used, cause a rise in protein catabolism, as has been observed with dogs and swine. This may be due in this experiment to a greater dilution of the ammonium salts incident to a large consumption of water by this class of animals.

"Data are also given on calcium and phosphorus metabolism during both neutral and acid periods of low nitrogen intake, as well as on a period of high nitrogen intake. Very probably the skeleton was not drawn upon for calcium during the period of lowest acid ingestion. Only on a high acid ingestion did it appear probable that decalcification of the bones began and then only a withdrawal of calcium carbonate.

"From the records submitted on growth and reproduction it is believed that natural acid rations, if otherwise satisfactory, are as effective for growth or reproduction as those of basic character. However, until it has been shown conclusively that less vigorous individuals will tolerate acid rations with perfect impunity, we are not warranted in making too sweeping conclusions."

Relation of different fats to animal growth (*Wisconsin Sta. Bul.* 250 (1915), pp. 47, 48).—In continuation of work previously noted (E. S. R., 31, p. 864) it has been found that milk fat can be converted into soaps without destroying its peculiar constituent, and that when olive oil is shaken with a solution of these soaps the vital principle is transferred to the olive oil and it will then induce growth in the same manner as butter fat alone. See also a previous note by McCollum and Davis (E. S. R., 32, p. 360).

Effect of poison on germ cells (*Wisconsin Sta. Bul.* 250 (1915), pp. 44-46, fig. 1).—In continuation of work by L. J. Cole previously noted (E. S. R., 31, p. 876) it is concluded that lead poisoning so acts on the germ cells of the

sire as to produce an appreciable decrease both in size and vitality of offspring. In experiments with chicks the results, as indicated by the infertility of eggs and the death of embryos or young chicks soon after hatching, showed that the influence of lead poisoning in the case of the male distinctly affected the vitality of the offspring.

Physiology of reproduction (*Wisconsin Sta. Bul. 250 (1915), p. 46*).—In trials with guinea pigs by L. J. Cole and H. Ibsen it has been shown that the size of offspring is controlled to some extent by the length of the gestation period, the young being smaller with a short period. The size of the mother, kind and amount of her food, and her ability to utilize it for the development of the fetuses are even more important in determining the size of offspring. Small and young mothers tend to produce small offspring, especially when the litter is large. With small litters the weight of the mother increases up to parturition. With large litters, however, her weight remains stationary or even drops during the last days of pregnancy, evidently due to the fact that all the nutrients in the food are required for merely maintaining the weight of the mother and fetuses. Numerous weighings have disproved the assumption that female young gain steadily from the day of birth while males lose in weight. There is no correlation with sex in this respect, both sexes tending to lose in weight during the first few days. Neither is there any constant relation between the size of individuals and the order of their birth in the litter.

Sex studies.—VII, On the assumption of male secondary characters by a cow with cystic degeneration of the ovaries, R. PEARL and F. M. SURFACE (*Maine Sta. Bul. 237 (1915), pp. 65-80, pls. 3*).—This paper describes the reproductive history of a cow, which presents the following points of interest.

"The cow was initially a perfect female, bearing calves and making a very high milk record. Later she failed to come in heat, and gradually, but in the end to a very marked degree, took on male secondary sex characteristics, both in behavior and structure. The gonads of this animal, examined subsequent to the change in secondary characters, were exactly like those of a normal cow, save in the one respect that the follicles were not breaking and discharging ova, but were forming follicular cysts, or becoming atretic, and because of this no corpora lutea were formed. The interstitial secreting mechanism of these ovaries was absolutely normal, both in respect of number of cells and the cytological characteristics of the individual cells.

"The evidence from this case strongly suggests that one function of the corpus luteum, through its internal secretion, is to maintain in full development the female secondary sex characters. Repeated injections of a suspension of the desiccated substance of the anterior lobe of the pituitary body failed to bring about any change in the sex behavior of this cow after it had assumed a male character."

Sex ratios in pigeons, together with observations on the laying, incubation, and hatching of the eggs, L. J. COLE and W. F. KIRKPATRICK (*Rhode Island Sta. Bul. 162 (1915), pp. 463-512, figs. 5*).—A continuation of the work noted above.

It was found that "the normal ratio of the sexes of pigeons hatched is 105 males to 100 females. The death rate of squabs is especially high for the first two or three days after hatching, and at about 10 to 15 days of age. When the two squabs are of distinctly different size before the banding age (10 to 15 days), the larger squab is more often a male than a female. The death rate for the two sexes, in bisexual broods, is essentially equal. There is no marked tendency for one sex to be weaker than the other in bisexual broods, and there is

only a slight indication that more males than females from such broods survive to adult life—placed at six months.

“A consideration of the ratio of males to females in each of the age groups does not indicate a high relative mortality of females in the ages preceding the adult state. There is a high mortality of both sexes during the first two or three years of their adult life, and this is especially high in the females between the ages of one and two years. The higher mortality of females at early adult ages, together with the higher proportion of males hatched (105:100), may be in large part responsible for the prevailing notion of a considerable excess of male pigeons in adult populations and seems to furnish real substantiation for this notion. The fact that males are generally more easily recognized than females probably adds to this impression.

“The number of unisexual broods, in which the squabs are either both male or both female, somewhat exceeds in our records the bisexual broods (one squab of each sex), but the odds against the numbers obtained representing a potential equality are very slight. These facts are directly contradictory to the statements that the two eggs usually produce a male and a female squab. Considering only the unisexual broods, the number of ‘both males’ to ‘both females’ is practically equal.

“A comparison of the numbers of each sex hatched from first eggs and from second eggs, respectively, shows no tendency for the former to produce exclusively males and the latter females, but as a matter of fact more males than females are hatched from both.

“The mean time of laying of the first egg is about 5 p. m., and of the second egg about 1 o'clock in the afternoon of the second day following. The mean interval between the laying of the two eggs is practically 44 hours. The mean time between the laying of the first and second eggs decreases progressively in the months from February to July, inclusive. There is a very sensible positive correlation between the time of laying of the first and of the second egg. The equation of the regression curve is given, which enables one to calculate the most probable time of laying of the second egg when the time the first was laid is known.

“The mean time of hatching of the first egg is 16.5 days after the laying of the second. The mean time of hatching of the second egg is 17 days after it is laid. On the average, therefore, the time from laying to hatching of the first egg is nearly a day and a half longer than it is for the second egg. This is probably to be accounted for by the fact that the first egg receives very little incubation until the second is laid. There is a high correlation between the times of hatching of the two eggs of a clutch.

“So far as the data presented go, they appear to indicate that sex in pigeons is determined according to the laws of chance.

“In case the eggs do not hatch they are seldom abandoned at the end of the normal period of incubation, but the birds continue to sit on them for a time longer. The length of time they will continue to incubate the eggs varies, but averages practically six days after the normal period, making the mean total time of incubation when the eggs do not hatch 23 days after the laying of the second egg. This continuance of incubation beyond the normal time under such circumstances constitutes a ‘factor of safety’ in the incubating instinct. A pair of mourning doves continued to sit on substituted eggs for four days after their own had hatched in an incubator, thus disproving Raspail's assertion that wild birds have an ‘exact notion of the time required for the eggs to hatch.’”

References are appended.

Studies on inheritance in pigeons.—II, A microscopical and chemical study of the feather pigments, O. LLOYD-JONES (*Jour. Expt. Zool.*, 18 (1915), No. 3, pp. 453-509, figs. 63).—This is a continuation of work previously reported (*E. S. R.*, 31, p. 572), and the results are summarized as follows:

“The six fundamental self colors of tumbler pigeons have been accounted for by the interaction of four genetic factors: *R*, red; *B*, black; *I*, intensity; *S*, spreading. Evidence as to the nature of the factor *B* has been secured from its effect on the feather pigment with respect to (a) color, (b) manner of formation and distribution, (c) physical form, and (d) chemical properties. All of these seem to indicate a different mechanism from that which produces red pigment, rather than simply a later stage of the same process. If uninfluenced by other factors, the final result of the pigmentation process in a bird carrying *B*, is the clumping of the pigment into the middle of the barbule cells. The factor *S* when present stops this clumping process and results in a ‘spread’ condition of the pigment. *S* may properly be considered as an inhibitive or ‘stopping factor.’

“As regards the increment of pigment substance, factor *I* probably has a constant effect when acting on dilute birds of different constitutions, namely, to increase by about three times the amount of pigment produced. As regards its influence on granule shape, on the other hand, it reacts in a different manner with each combination of factors. The facts concerning the granule shape in blacks suggest the possible existence of a factor not yet determined which is specifically concerned with granule shape.

“Genetic research which is confined only to obvious characters is often superficial, and in such cases microscopic research is necessary to distinguish the independently heritable characters involved.”

A bibliography is included.

Inspection of feeding stuffs, A. W. CLARK (*New York State Sta. Bul.* 404 (1915), pp. 221-334).—Analyses are given of the following feeding stuffs: Cotton-seed meal, linseed meal, malt sprouts, distillers' dried grains, brewers' dried grains, corn gluten feed, corn gluten meal, hominy feed, molasses feeds, tankage, meat meal, meat scrap, blood flour, beef scrap, fish scrap, alfalfa meal, wheat bran, wheat middlings, ground buckwheat screenings, corn meal, barley middlings, corn bran, wheat screenings, ground corn screenings, flax screenings, pea meal, dried beet pulp, shredded wheat waste, and various mixed and proprietary feeds.

Analyses of feeding stuffs, P. H. WESSELS ET AL. (*Rhode Island Sta. Insp. Bul.*, 1915, May, pp. 16).—Analyses are reported of beef scrap, fish scrap, meat and bone scrap, cotton-seed meal, linseed meal, gluten meal, gluten feed, malt sprouts, distillers' grains, malt screenings, wheat shorts, middlings, bran, hominy feed, alfalfa meal, and various mixed and proprietary feeds.

How to comply with the law regulating the sale of concentrated feed stuffs in Texas, [and] other information, B. YOUNGBLOOD (*Texas Sta. Circ.* 6, n. ser. (1915), pp. 14).—This circular gives the text of the law regulating the sale of feeding stuffs in the State of Texas, and gives directions for complying with this law.

Cattle feeding.—X, Winter steer feeding, 1913-14, J. H. SKINNEB and F. G. KING (*Indiana Sta. Bul.* 178 (1914), pp. 343-384).—This is a continuation of work previously noted (*E. S. R.*, 30, p. 767). The object was to determine the comparative value of leguminous hay alone and in combination with corn silage as roughage for full-fed cattle; to compare oat straw and leguminous hay as dry roughage for full-fed cattle receiving all the corn silage they will eat; to compare different quantities of cotton-seed meal in rations containing

corn silage for fattening cattle; to compare ground soy beans and cotton-seed meal as sources of protein for supplementing rations for fattening cattle; and to test the comparative value of clover hay and alfalfa hay as roughage for fattening cattle.

Seven lots of ten choice high-grade Shorthorn steers each, weighing approximately 1,000 lbs. per head, were fed from November 20, 1913, to May 14, 1914, with the results shown in the table following. Each lot contained ten 105-lb. hogs which were fed corn in addition to the droppings from the cattle, and lots 1, 2, and 6 were fed a small quantity of shorts and tankage.

Summary of steer-feeding experiments.

Lot.	Daily feed consumed per steer.						
	Shelled corn.	Cotton-seed meal.	Clover hay.	Alfalfa hay.	Corn silage.	Oat straw.	Ground soy beans.

The addition of corn silage to rations of grain and leguminous hay slightly increased the rate of gain made by the cattle, but had little effect on the finish of the cattle. The substitution of oat straw for leguminous hay had little effect other than a reduction in the cost of gain. Larger profits were secured from a ration containing oat straw and a well-balanced ration containing corn silage than when leguminous hay was fed instead of oat straw.

Cattle fed ground soy beans in addition to corn, oat straw, and corn silage maintained very eager appetites for three months but thereafter had very poor appetites, while cattle fed cotton-seed meal maintained eager appetites for six months. Ground soy beans had a laxative effect on the cattle. Cattle fed ground soy beans as supplement did not gain as rapidly during the last three months as others fed cotton-seed meal. The cattle fed ground soy beans were valued 10 cts. per hundred lbs. less than those fed cotton-seed meal.

Cattle fed shelled corn, cotton-seed meal, and clover hay consumed a larger quantity of grain and a smaller amount of hay than those fed shelled corn, cotton-seed meal, and alfalfa hay. Cattle fed hay in connection with corn silage and grain consumed a larger quantity of alfalfa than of clover hay. Cattle fed clover hay as the only roughage or in combination with corn silage made fully

as rapid gains as those fed alfalfa hay, and the gains were made more economically either from the standpoint of feed consumed or financial cost.

Corn silage and alfalfa hay for beef production. R. K. BLISS and C. B. LEE (*Nebraska Sta. Bul. 151 (1915), pp. 43, figs. 16*).—Six lots of seven or eight 2-year-old steers each were fed 157 days, as follows: Lot 1, ground corn, cotton-seed cake, and prairie hay; lot 2, ground corn, corn silage, and cotton-seed cake; lot 3, ground corn, corn silage, and prairie hay; lot 4, ground corn, a heavy feed of corn silage, and alfalfa hay; lot 5, ground corn, a medium feed of corn silage, and alfalfa hay; and lot 6, corn and alfalfa hay. These steers made average daily gains per steer of 1.93, 2.01, 1.75, 2.24, 2.04, and 2.29 lbs., costing 9.51, 9.29, 9.08, 7.79, 8.31, and 7.22 cts. per pound of gain. The net profit per steer was \$9.42, \$7.31, \$8.93, \$14.50, \$13.47, and \$20.59 for the respective lots. The average shrinkage in marketing was estimated to be 27, 44, 17, 30, 30, and 8 lbs. per steer, and the dressing percentages 61.65, 61.28, 60.52, 60.94, 61.52, and 60.71 for the respective lots.

In a second experiment eight lots of from six to eight 2-year-old steers each were fed 154 days, as follows: Lot 1, ground corn and alfalfa hay; lot 2, ground corn, alfalfa hay, and wheat straw; lot 3, ground corn, alfalfa hay, and a light feed of silage; lot 4, ground corn, a medium feed of silage, and alfalfa hay; lot 5, ground corn, a heavy feed of silage, and alfalfa hay; lot 6, ground corn, alfalfa hay, and a heavy feed of silage at the beginning, which gradually decreased to a light feed at the close of the feeding period; lot 7, ground corn, alfalfa hay, a medium feed of silage, and cotton-seed cake; lot 8, ground corn, a heavy feed of silage, cotton-seed cake, and alfalfa hay during the first five weeks. These steers made average daily gains per steer of 2.1, 1.86, 2.1, 2.1, 2.1, 2.07, 2.05, and 2.07 lbs., costing 10.82, 12.23, 11.31, 11.77, 11.74, 11.49, 12.04, and 12.76 cts. per pound of gain. The net profit per steer was -15 cts., -\$4.22, 42 cts., -\$4.11, -\$2.35, -\$3.42, -\$5.89, and -\$6.30 for the respective lots.

The results of the two experiments are summarized as follows: "A ration of corn and alfalfa hay produced the cheapest gains of any ration used. Furthermore, the steers fed corn and alfalfa hay made as rapid gains as did the steers on any other ration. Had the alfalfa hay used in the first experiment cost \$20 per ton, the average profit on the three lots receiving alfalfa would have been 15 per cent greater than the profit on the best one of the three lots not receiving alfalfa. Cold pressed cotton-seed cake did not give as good results, as regards either rate of gain or economy of gain, as did alfalfa hay in a ration for fattening steers. The addition of cold pressed cotton-seed cake to a ration of corn, silage, and alfalfa increased the cost of gain and lowered the profits on the steers. The steers receiving silage without exception shed their coats early in the spring and at all times presented a sleek and sappy appearance. Contrary to preceding experiments, a heavy feed of silage with alfalfa hay and corn gave as rapid gains as did either a medium or a light feed of silage with alfalfa hay and corn. The amount of silage which can best be fed to fattening steers apparently must be regarded as unsettled. The steers fed silage in connection with corn and alfalfa suffered a very slight shrinkage when shipped to market. Different amounts of silage seemingly had no effect upon the number of pounds shrinkage. Where prairie hay was used in place of alfalfa, small and expensive gains resulted.

"The individuality of a steer is a very important factor in the rate of gain. The average difference in gains made between the highest and lowest producing steer in each of the 14 different lots was 120 lbs. In practically all cases there was a greater variation in the daily gains made by steers in the same lot than there was in the average daily gains of the different lots. Usually a considerable

difference can be noted between poor and good feeder cattle, but sometimes even a careful study of steers does not reveal their feeding possibilities. An advance of 8 cts. per bushel in the price of corn increased the cost of gains \$1 per 100 lbs. In the second experiment, where a ration of corn and alfalfa hay was fed, an increase of 1 ct. per bushel in the price of corn had the same effect in increasing the cost of gains as did an increase of \$1 per ton in the price of alfalfa hay."

Raising calves on skim milk, O. E. REED (*Kansas Sta. Circ. 48 (1915), pp. 11, figs. 4*).—A general discussion of methods of feeding calves on skim milk, including data previously noted (E. S. R., 16, p. 1111).

Sheep feeding.—IV, Fattening western lambs, 1913–14, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul. 179 (1914), pp. 385–404*).—Continuing previous work (E. S. R., 30, p. 769), nine lots of 25 choice Idaho lambs, weighing approximately 60 lbs. per head, were fed from November 14, 1913, to February 22, 1914, with the results shown in the following table:

Summary of lamb feeding experiments.

Lot.	Ration.	Average daily feed consumed per lamb.					Average daily gain.	Cost per pound of gain.	Profit per lamb.

The addition of corn silage to a ration of shelled corn and clover hay reduced the hay consumption and slightly reduced the quantity of grain eaten and the rate of gain made by the lambs. It also reduced the cost of gain 0.49 cts. per pound, slightly increased the selling value of the lambs, and increased the profit 22 cts. per lamb.

Lambs fed corn silage as the only roughage or corn silage and oat straw as roughage had irregular appetites and required great care to prevent their going "off feed." The addition of oat straw to a ration of shelled corn, cotton-seed meal, and corn silage had no beneficial effect on the ration. The addition of clover hay to a ration of shelled corn, cotton-seed meal, and corn silage produced excellent appetites in the lambs, and greatly increased the quantity of feed eaten and gains made by the lambs.

The addition of cotton-seed meal to a ration of shelled corn, clover hay, and corn silage increased the appetites of the lambs for both grain and hay and increased the rate of gain. A grain mixture of seven parts corn and one part cotton-seed meal proved slightly more effective for producing rapid gains and on less feed than a grain mixture of four parts corn and one part cotton-seed meal.

Specific effects of rations on the development of swine, F. B. FORBES, F. M. BEEGLE, C. M. FRITZ, L. E. MORGAN, and S. N. RHUE (*Ohio Sta. Bul. 283 (1915), pp. 111-152, figs. 12*).—This is a continuation of work previously noted (*E. S. R.*, 22, p. 771), and of a preliminary metabolism study (*E. S. R.*, 31, p. 268).

Seven lots of five pigs each were used in a feeding and carcass-analysis experiment in a study of the specific effects of rations on the composition of the growth produced. The rations were corn alone, and corn supplemented by soy beans, wheat middlings, linseed-oil meal, tankage, and skim milk. These rations were fed in quantities such as contained the same amount of digestible nutrient per unit of live weight of the pigs. The supplemented rations contained the same proportions of protein to nonnitrogenous starch equivalent. The experiment was in large measure a comparison of the capacities of pigs to grow on equivalent amounts of protein from different sources.

The capacity of digestible milk protein to cause proteid increase was shown to be greater than that of digestible protein from the vegetable foods used and from tankage. None of the supplements, used in proportions such that the nutritive ratios of the rations are as 1 : 6.5, apparently furnished mineral matter of the amounts and kinds requisite to maximum growth of bones. The rations of corn alone and of corn and soy beans produced the least bone, and that of corn supplemented by tankage and by skim milk the most bone.

The lot which received corn and linseed oil meal produced the largest percentage of flesh and leaf fat (together) and the smallest percentage of bone, as related to the gross-dressed carcass, of any lot in the series. The lots which received tankage and skim milk had the largest proportions of bone to gross-dressed carcass, except for the lots which received corn alone, and corn and soy beans, in which latter cases the higher proportion of bone to gross-dressed carcass was due not to superior development of bone, but to inferior nourishment of other tissues. The proportions of calcium, magnesium, and phosphorus in the bones tended strongly to remain constant, but may be modified to a certain extent by the limitations of the food. The amounts of these elements in the bone, however, are susceptible of much greater modification through the composition of the food. The ash per gram of the bones and the breaking strength of the bones were shown to vary together in the following order of decreasing magnitude: Corn and skim milk; corn and tankage; corn and linseed oil meal; corn alone; corn and wheat middlings; and corn and soy beans. The calcium and phosphorus content of the skeleton was lower than in the check lot (killed at the beginning of the experiment) in all lots except those which received tankage and milk. The magnesium content of the skeletons of the pigs which received wheat middlings (a food very rich in magnesium) was higher than in the check lot.

The ration of corn alone produced less moisture, protein, and ash, and more fat in the flesh than did any of the supplemented rations, while the ration of corn and skim milk produced the maximum of moisture and protein and the minimum of fat in the flesh. There was marked variation in the content of the flesh and blood in the mineral constituents, apparently as determined by the food. Excluding the check lot, the sodium in the flesh varied between 0.0635 and 0.1036 per cent, potassium between 0.1888 and 0.2419 per cent, calcium between 0.0217 and 0.0319 per cent, magnesium between 0.0146 and 0.0188 per cent, sulphur between 0.1289 and 0.1799 per cent, chlorine between 0.0353 and 0.0679 per cent, and phosphorus between 0.1227 and 0.1506 per cent. There was also much variation in inorganic phosphorus and in lecithin, especially the latter (0.0147 to 0.0273 per cent).

One-half of each carcass was cured. The foods were found to have produced marked differences in the firmness of the hams and bacon, and certain effects on their behavior in cooking; also slight effects on the acceptability of the cooked meat. One-half of each carcass was analyzed and a complete chemical accounting made. The data show that there is a specific effect of the ration on the proportions of the main tissue components.

The proportion of protein to ether extract in the flesh ranked as follows in the respective lots: Corn lot 1:6.66, corn and soy beans 1:5.65, corn and linseed meal 1:6.3, corn and middlings 1:5.87, corn and tankage 1:6.34, corn and skim milk 1:5.03, check lot 1:4.52. The proportion of protein to ash in the bones in the respective lots ranked as follows: Corn 1:1.13, corn and soy beans 1:0.957, corn and linseed meal 1:1.139, corn and middlings 1:0.928, corn and tankage 1:1.171, corn and skim milk 1:1.171, check lot 1:1.076. The proportion of protein to ether extract and to ash in the gross-dressed carcass, as a whole, ranked as follows in the respective lots: Corn lot 1:5.12:0.178, corn and soy beans 1:4.45:0.17, corn and linseed meal 1:4.91:0.169, corn and middlings 1:4.43:0.159, corn and tankage 1:4.88:0.197, corn and skim milk 1:3.93:0.179, check lot 1:3.36:0.199.

Complete histological blood analyses were made for each pig. Certain individual differences were related to the state of nutrition of the animals within an experimental lot, while other observations were considered to be specific or characteristic for the lot and ration. The following conditions seemed to be more certainly characteristic than others: In the corn lot the low hemoglobin content, the maximum percentage of polymorphs and minimum percentage of lymphocytes; in the tankage lot the uniformly high hemoglobin content; in the milk lot the large number of white corpuscles; and in the linseed meal and milk lots the low percentage of polymorphs and high percentage of lymphocytes.

Catalase estimations were made on the more important organs and tissues, and certain differences noted. The very high catalase content of the blood and the low content of the flesh suggest that the catalase content of the latter is likely to be influenced by the blood which it normally contains. That the flesh of the milk lot should have no catalase suggests that all of the catalase of the flesh is due to blood contained therein, and possibly that the skim milk has such an effect on the musculature of the blood vessels as results in more complete bleeding out than occurs under the influence of other foods. In the brain the catalase varied comparatively little, but was lowest in the skim milk lot. In the blood it was lower in the lots containing the largest proportions of corn than in others, and practically as large in the skim milk lot as in any other. The low catalase values for brain and muscle in this lot are ascribed not to a general condition in these animals but to special conditions within the particular tissues. The catalase of the liver of the linseed meal and tankage lots appeared to be significantly low, while in the kidneys there were probably no significant differences. The catalase in the spleens varied rather widely, from 8.06 cc. of oxygen liberated per gram of substance in the tankage lot to 15.07 cc. in the corn lot.

It is said that the results of these studies reflect the great poverty of cereals in lime, as an element of the food of animals, it being clearly proved that normal growth of the skeleton can not be sustained by the grains. This fact calls especial attention to the leguminous roughages, which, because of their high protein and unparalleled lime content, are deemed the ideal natural supplementary foods for use with the grains.

Pork production, W. P. SNYDER (*Nebraska Sta. Bul. 147 (1915)*, pp. 56, figs. 6; *popular ed.*, pp. 5-31, figs. 5).—This bulletin summarizes and continues work

conducted at the North Platte substation and previously noted (E. S. R., 27, p. 470).

Two lots of 10 yearling or older brood sows each were wintered on corn and alfalfa during four successive winters. One lot was fed shelled corn in a trough or on clean ground and a good quality of alfalfa hay in a rack; the other lot was fed a ration of ground corn mixed with an equal weight of chopped alfalfa and moistened with water. During the fourth winter corn was replaced by wheat. The average daily gains per head were 0.76 and 0.79 lb., the amount of grain consumed per pound of gain 6.8 and 5.3 lbs., the amount of alfalfa consumed per pound of gain 1 and 5.39 lbs., the cost of feed per pound of gain 6.5 and 7.54 cts., the cost of feed for wintering the sow \$5.29 and \$6.92.

Spring gilts were summer pastured on alfalfa and wintered on a mixture of alfalfa and grain 1:2 or 1:3 during five winters, receiving on the average 2.48 lbs. of feed per 100 lbs. live weight per day. They made an average daily gain during the winter of 0.91 lb. per gilt, requiring on the average 4.77 lbs. of grain and 1.81 lbs. of alfalfa per pound of gain, and costing 5.3 cts. That no trouble occurred at the time of farrowing and that fairly large, healthy litters were farrowed is deemed an indication that the ration has some merit. It is thought that a smaller percentage of alfalfa probably would have given cheaper as well as faster gains but would have kept the gilts too fleshy unless the amount fed had been kept considerably below a full feed.

Old and young sows fed during four winters on corn and alfalfa farrowed an average of 11.1 and 8.2 pigs per sow, respectively, the pigs weighing 2.4 and 2.31 lbs. each at birth, and raised 6.55 and 6.2 pigs per sow. The pigs gained at the rate of 0.53 and 0.5 lb. each daily and reached the 50-lb. weight when 89 and 99 days old. The average cost of all the feed used by the sows and their litters was \$17.41 and \$16.41. Crediting the sow with her gain in weight, the average cost of the feed used in producing a 50-lb. pig from old sows is estimated at \$2.11 and that with young sows at \$1.68.

It was found that the cost of producing a spring pig to the weight of 50 lbs. was \$2.05 and that of the fall pig \$2.03. A spring pig from a young sow cost \$1.81 as compared with \$2.05 for a spring pig from an old sow. The young sows raised nearly as many pigs and grew them to the 50-lb. weight nearly as quickly as the old sows.

In trials to determine the cost of growing pigs on alfalfa pasture and grain, 202 pigs were kept on alfalfa pasture and fed 2.75 lbs. corn per 100 lbs. live weight per day. The pigs made an average daily gain of 0.72 lb. per pig, consuming 3.55 lbs. of corn per pound of gain, which, together with the alfalfa consumed, cost 3.54 cts. per pound of gain. In a second experiment, six lots of 25 pigs each, fed on alfalfa pasture and corn, or corn and shorts (2.12 lbs. of grain per 100 lbs. live weight per day), made an average daily gain of 0.51 lb. per pig, consuming 3.13 lbs. of grain per pound of gain, which, together with the alfalfa fed, cost 3.57 cts. per pound of gain. The lots fed corn alone when grazing on alfalfa pasture made practically as rapid and as cheap gains as the lots fed corn and shorts.

Six lots of from 19 to 25 pigs each fed 83 days on alfalfa pasture and soaked or dry shelled corn (2.39 lbs. per 100 lbs. live weight per day) made an average daily gain of 0.66 lb. per pig, consuming 2.86 lbs. of grain per pound of gain, which, together with the alfalfa consumed, cost 3.05 cts. per pound of gain. The dry corn and soaked corn gave the same rate of gain with nearly the same amount of corn consumption, indicating that it was not profitable to soak corn for these pigs.

A lot of 25 gilts during five consecutive summers on alfalfa pasture and fed 2.5 lbs. of grain (corn or corn and wheat) daily per 100 lbs. live weight consumed an average of 3.39 lbs. of grain per pound of gain, made at the average rate of 0.92 lb. daily per head and costing 3.35 cts.

Summarizing the records of the various lots fed grain while grazing on alfalfa pasture, it is found that with the pigs on a 2, 2½, and 3 per cent grain ration the relative daily gains of the three groups were almost the same as the relative amounts of grain fed to the three groups. The ratio of the cost of grain and pasture for 100 lbs. of gain was 81, 84, and 100, respectively, with corn at 47 cts. per bushel. As the price of corn is increased the difference in the cost of gains becomes greater and is more in favor of the lighter rations. The ratio of the daily profit per pig with corn at 47 cts. per bushel and hogs \$5.90 per 100 lbs. is 76, 85, and 100, and with corn at 70 cts. per bushel and hogs \$7.50 per 100 lbs., 91, 100, and 100. The higher prices favor the lighter ration of 2 per cent, but do not bring as much profit from this ration as from the heavier rations. It is thought that rations lighter than 2½ or 2 per cent are not as profitable as these rations even with the price of corn high, as the light rations do not permit of sufficient growth to keep the hogs in a healthy and thrifty condition.

In a comparison of various ways of feeding corn and protein supplements to corn in fattening hogs, 10 lots of 10 130-lb. pigs each were fed 106 days, as follows: Lot 1, shelled corn; lot 2, ear corn and alfalfa hay in a rack; lot 3, shelled corn and alfalfa hay in a rack; lot 4, ground corn and alfalfa hay in a rack; lot 5, ground corn and alfalfa meal 9:1; lot 6, ground corn and shorts 9:1; lot 7, ground corn and oil meal 9:1; lot 8, ground corn and tankage 19:1; lot 9, ground corn and oil meal 9:1, and alfalfa hay in a rack; and lot 10, ground corn and tankage 19:1, and alfalfa hay in a rack. These pigs made average daily gains of 0.78, 0.79, 0.78, 0.9, 1, 1.05, 1.24, 1.25, 1.25, and 1.26 lbs. per pig, consuming 6.1, 5.86, 6.03, 5.97, 5.36, 5.11, 4.67, 4.69, 4.87, and 4.84 lbs. of feed per pound of gain, costing 5.13, 4.8, 4.93, 4.93, 4.45, 4.47, 4.23, 4.21, 4.29, and 4.14 cts. per pound of gain, and realizing a profit of 64 cts., 92 cts., 80 cts., 93 cts., \$1.53, \$1.59, \$2.20, \$2.25, \$2.13, and \$2.35 per hog for the respective lots.

In a second experiment 11 lots of 9 or 10 100-lb. pigs each were fed 109 days rations corresponding to the above except that lot 1 received ground corn and lot 11 ground corn and cotton-seed cake 9:1. These pigs made average daily gains of 1.22, 1.52, 1.52, 1.33, 1.24, 1.34, 1.41, 1.46, 1.41, 1.47, and 1.48 lbs. per pig, consuming 4.94, 4.24, 4.46, 4.82, 4.97, 4.61, 4.45, 4.41, 4.55, 4.47, and 4.54 lbs of feed per pound of gain, costing 4.15, 3.5, 3.63, 3.93, 4.13, 4.04, 4.03, 3.96, 4.08, 4, and 4 cts. per pound of gain, and realizing a profit of \$2.34, \$3.99, \$3.78, \$2.86, \$2.41, \$2.72, \$2.88, \$3.08, \$2.81, \$3.04, and \$3.07 per pig for the respective lots.

One group of seven lots of 10 108-lb. pigs was fed 98 days, as follows: Lot 1 shelled corn dry, lot 2 whole wheat dry, lot 3 whole wheat soaked, lot 4 ground wheat moistened, lot 5 ground wheat soaked, lot 6 whole rye soaked, and lot 7 ground rye moistened. This group received alfalfa hay in racks in addition. A second group of six lots were fed the same rations as lots 1 to 6, inclusive, of the first group, but without alfalfa hay. The pigs of the corresponding lots of these two groups made average daily gains of 1.11, 1.02, 1.05, 1.36, 1.41, and 0.88 lbs. per pig, consuming 4.79, 5.19, 5.14, 4.33, 4.18, and 5.58 lbs. of feed per pound of gain, costing (with corn at 47 cts. per bushel, wheat at 70 cts. per bushel, and hogs at 5.9 cts. per pound) 3.97, 5.99, 5.92, 5, 4.84, and 5.51 cts. per pound of gain, and realizing a profit of \$2.11, a loss, a loss, \$1.21, \$1.46, and 34 cts. per pig for the respective lots. The single test with ground rye indicated that 1 bu. of ground rye produced the same gain as 1.15 bu. of whole rye, and gave a very much faster gain.

Two lots of 32 115-lb. pigs each were grazed for 70 days on alfalfa pasture, lot 1 being fed 3.34 lbs. of ground corn daily per 100 lbs. live weight, and lot 2, 3.3 lbs. of a mixture of corn and shorts 2:1, during which time they made an average daily gain of 1.09 and 1.04 lbs. per pig, consuming 4.62 and 4.81 lbs. of feed per pound of gain, costing 3.88 and 4.62 cts. per pound of gain, and realizing a profit of \$1.54 and 94 cts. per pig for the respective lots. During the next 49 days the pigs were kept in dry lots and fed the grain rations with alfalfa hay in racks, and made an average daily gain of 0.86 and 0.92 lb. per pig, consuming 6.16 and 6.21 lbs. of feed per pound of gain, costing 5.13 and 5.89 cts. per pound of gain, and realizing a profit of 32 and 0.4 cts. per pig for the respective lots.

Two lots of 10 50-lb. pigs each were fed 51 days as follows: Lot 1 corn and shorts 3:1 and cut alfalfa, and lot 2 corn and shorts 3:1, cut alfalfa and alfalfa tea. The alfalfa tea was used in making a slop feed. These lots made relative gains of 94 and 100, respectively. Two other lots of 13 69-lb. pigs each were similarly fed, lot 2 receiving alfalfa tea grounds instead of the tea, the relative gains being 84 and 100, respectively. The tea from 100 lbs. of stewed alfalfa thus saved 47 lbs. of corn, and the tea grounds from 100 lbs. of stewed alfalfa saved 67 lbs. of corn.

In a second experiment in which a lot of 14 56-lb. pigs was fed 84 days ground corn and chopped alfalfa hay 9:1, and a second lot received the same ration mixed and moistened with alfalfa tea, together with the tea grounds, a slight advantage in favor of the alfalfa tea was obtained, but not enough to warrant the farmer in going to much, if any, expense to stew alfalfa for hogs.

The following table gives a summary of averages of various tests:

Summary of averages and comparison of rations.

Kind of ration.	Number of tests conducted.	Number of pigs tested.	Daily gain per pig.	Feed per pound of gain.	Cost per pound of gain.	Profit per pig.
			<i>Lbs.</i>	<i>Lbs.</i>	<i>Cts.</i>	
Corn.....	10	168	0.94	4.36	3.66	\$1.70
Corn, shorts.....	10	168	.94	4.33	4.07	1.34
Corn.....	8	132	1.19	4.78	4.04	1.78
Corn, barley.....	8	132	1.10	5.32	4.48	1.26
Corn.....	3	84	1.33	4.77	3.95	1.95
Corn, emmer.....	3	84	1.14	5.29	4.48	1.38
Corn.....	4	64	1.30	5.01	4.01	2.33
Corn, wheat.....	4	64	1.22	4.70	4.53	1.71
Corn.....	7	162	1.17	5.11	4.26	1.83
Corn, tankage.....	7	162	1.45	4.59	4.08	2.45

Profitable hog feeding, W. HISLOR (*Washington Sta. Popular Bul. 87 (1915), pp. 8*).—A discussion of the value of tankage, skim milk, buttermilk and whey, soy bean meal, linseed oil meal, wheat middlings, wheat bran, alfalfa and clover hay, and cotton-seed meal as supplements to farm-grown grains for hog feeding.

Alfalfa pasturing experiment, R. W. ALLEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Umatilla Expt. Farm, 1914, pp. 8, 9, fig. 1*).—Four 84-lb. pigs, pastured 135 days from March 28 to August 11, 1913, on two plats of $\frac{1}{2}$ acre each of 4-year-old alfalfa and fed $1\frac{1}{2}$ lbs. of rolled barley per 100 lbs. live weight per day, gained an average of 106 lbs. per pig. Four 89-lb. pigs, pastured 55 days from August 11 to October 6 on the same plats of alfalfa and fed $1\frac{1}{2}$ lbs. of rolled barley per 100 lbs. live weight per day, gained an average of 32 lbs. per pig. The $\frac{1}{2}$ acre of alfalfa supplemented by 1,883 lbs of grain produced

a total of 573 lbs. of pork, and a net return of \$47.48 per acre. Feeding the alfalfa in this manner saved the expense of harvesting the hay and retained the manure produced by the pigs.

Rape pasture for pigs in cornfield.—Kaoliang for pigs, J. W. WILSON (*South Dakota Sta. Bul. 157 (1914), pp. 131-143, figs. 5*).—The object of the first experiment was to determine the relative feeding value of several varieties of corn for hogging off purposes. Six lots of six 90- to 100-lb. pigs each were fed for six weeks as follows: Lot 1 Minnesota No. 13 corn, lot 2 Minnesota No. 13 corn and rape, lot 3 Wisconsin White Dent corn, lot 4 Wisconsin White Dent and rape, lot 5 Yellow Triumph flint corn, lot 6 Yellow Triumph flint corn and rape. The average daily gains per head were 1.04, 1.11, 1.08, 1.36, 1.05, and 1.38 lbs. for the respective lots.

The results indicated that flint corn is about equal to dent corn for pigs. There was a marked difference in the growth of rape in the different kinds of corn. The best growth was in the lot planted to Wisconsin White Dent corn, the next best in Yellow Triumph flint, and the poorest in Minnesota No. 13. The 18 pigs in the three lots receiving corn without rape made an average daily gain per head of 1.06 lbs., as compared with 1.28 lbs. for the 18 pigs receiving rape pasture in addition. The results obtained from the lot planted to rape and Minnesota No. 13 corn were poor, owing to the rank growth of the corn and the consequent stunted growth of the rape. It is concluded that the low-growing varieties of dent corn are to be preferred to the tall-growing varieties to secure a suitable growth of rape.

Four lots of four 150- to 250-lb. hogs each were fed for 55 days as follows: Lot 1 kaoliang meal and alfalfa hay, lot 2 kaoliang meal, lot 3 corn meal and alfalfa hay, and lot 4 corn meal. The average daily gains per head were 0.98, 0.87, 1.32, and 1.19 lbs., the consumption 5.81, 6.61, 4.63, and 5.22 lbs. per pound of gain, and the cost 6.56, 6.61, 5.19, and 5.22 cts. per pound of gain for the respective lots. Kaoliang grain is not deemed as good as corn for fattening pigs, but considering its drought-resisting qualities it is a better feed to grow in some sections than corn.

A metabolism crate for swine, E. B. FORBES (*Ohio Sta. Circ. 152 (1915), pp. 75-85, figs. 11*).—This circular gives plans and descriptions of a metabolism crate devised by the author and used in experimental work at the Ohio Station.

Rations for growing and fattening roasters and capons, W. J. BUSS (*Ohio Sta. Bul. 284 (1915), pp. 153-172, figs. 2*).—Five lots of 39 10-week-old chicks, 94 cockerels and 101 pullets, were selected June 18. All but 8 of the cockerels were caponized July 31. The pullets were removed soon after they began to lay, and the 8 cockerels December 3. The remaining birds were fed until January 27. The rations for the 32 weeks were as follows: Lot 1, corn and a mash of ground corn and beef scrap 2:1; lot 2, corn and a mash of ground corn and beef scrap 2:1 during the first week, the amount of corn being increased one part each week so that the mash for the thirty-second week was ground corn and beef scrap 32:2; lot 3, corn, wheat, and oats 11:15:4, and a mash of ground corn, bran, and beef scrap 2:2:1; lot 4, corn and a mash of ground corn and tankage 7:3; lot 5, corn and a mash of ground corn and oil meal 3:4, fed for 12 weeks, and replaced by a mash of ground corn and beef scrap 2:1 thereafter.

The birds made an average weekly gain of 0.202, 0.2, 0.206, 0.185, and 0.181 lb. per bird, consuming per pound of gain 7.32, 7.71, 8.45, 7.67, and 7.52 lbs. of feed per bird, and costing 9.09, 8.67, 11.66, 9.1, and 9.25 cts. per pound of gain for the respective lots. The capons made more rapid gains than did the pullets. For the entire time that they were in the experiment only 32 per cent of the capons gained less than 0.2 lb. per week, while 81 per cent of the pullets

gained less than this amount. During the first half of the experiment 27 per cent of the capons and 63 per cent of the pullets made average weekly gains of less than 0.2 lb. The average total gain for the pullets was 4.609 lbs. per head, for the capons 6.878 lbs., and for the cockerels 6.125 lbs. The eight cockerels in this experiment, however, had been selected for their large size and thrifty appearance, but it appears that with birds of equal thrift the advantage, so far as rate of gain is concerned, might be slightly in favor of the cockerels over capons.

Oil meal did not prove to be a satisfactory supplement for corn. Lot 5, given a ration of corn and oil meal for 12 weeks, gained less than one-fifth as much as lot 1.

In a second experiment similar to the first, except that the birds were all capons, were fed 19 weeks, and lot 5 was fed the same as lot 1 but was confined to the house, the birds made average weekly gains of 0.244, 0.237, 0.236, 0.242, and 0.201 lb. per bird, consuming per pound of gain 8.11, 8.61, 9.23, 8.16, and 9.5 lbs. of feed and costing 10.11, 10.27, 13.19, 9.79, and 11.88 cts. per pound of gain for the respective lots. The average shrinkage in killing was 0.508, 0.546, 0.561, 0.521, and 0.477 lb. per bird, and the percentage loss based on weight before killing was 6.58, 6.98, 7.49, 6.77, and 6.55 per cent for the respective lots.

The heaviest capons sold at the highest price per pound and the lightest at the lowest price. This shows the advisability of growing the capons to as large a size as possible, at a reasonable feed cost per pound of gain, before they are marketed. In lot 5 the capons confined to small pens from the beginning of the experiment, while consuming only 2 per cent less feed per bird, gained almost 17 per cent less per bird than did capons allowed range for the first 12 weeks of the experiment. The cost of feed per unit of gain was 17.5 per cent higher with the capons in confinement than with those on range.

An average of the two experiments on a percentage basis, using lot 1 as a standard for comparison and omitting lot 5, is, for rate of gain, 100, 98.2, 99.5, and 94.5; for average feed consumed per bird, 100, 104.8, 115.4, and 98.1; for feed consumed per pound of gain, 100, 105.1, 114.5, and 103.2; and for cost of feed consumed per pound of gain, 100, 97, 128.7, 98.8. Lot 2, receiving a ration which contained a constantly decreasing amount of protein, made a lower rate of gain at a higher feed consumption per pound of gain in both experiments than did lot 1, fed a ration which carried the same proportion of protein throughout the experiments. Lot 3 consumed the most feed per bird and per pound of gain. The cost of feed per pound of gain was 30.5 per cent higher with lot 3 than with lots 1, 2, and 4.

Essentials for growth of chicks, HELEN D. WHITAKER (*Washington Sta. Popular Bul. 91 (1915), pp. 4*).—A general discussion of the feeding and care of chicks, including data as to weights of Leghorns, Rhode Island Reds, and Plymouth Rocks from hatching to five weeks of age.

Wild fowl and poultry propagation (*Wisconsin Sta. Bul. 250 (1915), pp. 42-44, figs. 2*).—Successful trials by J. G. Halpin in propagating quail and wild mallard ducks are reported. It is said that the mallard is easy to domesticate, shows special ability to shift for itself, at even an early age, and makes rapid growth.

DAIRY FARMING—DAIRYING.

[Milk production] (*Wisconsin Sta. Bul. 250 (1915), pp. 46, 47*).—In a comparison by G. C. Humphrey and A. C. Oosterhuis of home-grown grains and purchased protein-rich concentrates, one lot of eight cows was fed a home-grown concentrate mixture of oats and corn 6:4; another lot, dried distillers' grains, wheat bran, oats, and cotton-seed meal 3:3:3:1; and a third lot, dried dis-

tillers' grains, wheat bran, oats, corn, and oil meal 7:7:3:2:1. In addition, the lots received all the alfalfa, mixed clover and timothy, and corn silage they would consume, together with 6.7 lbs. sugar beets per head daily. The purchased ration, having a nutritive ratio of 1:5.4, cost on the average 3.2 per cent more than the home-grown ration, which had a nutritive ratio of 1:7.9. However, the value of the milk fat and skim milk from the purchased ration was 9.4 per cent greater than from the home-grown, so that the purchase of these feeds returned a profit and in addition brought increased fertility to the farm.

The value of nitrogen of alfalfa hay for milk production (*Wisconsin Sta. Bul. 250 (1915), pp. 52, 53*).—A brief report of work previously noted (E. S. R., 32, p. 74).

Dairy problems (*Wisconsin Sta. Bul. 250 (1915), pp. 40-42*).—It is reported that pasteurized milk cheese, previously described (E. S. R., 31, p. 874), is being made with success under factory conditions. The manufacture of buttermilk cheese is also meeting with success.

In bottle washing trials the loss of milk bottles due to breakage and chipping in cleaning was found by A. C. Baer to be 2.73 per cent by the older methods and 0.75 per cent by the new mechanical treatment in cases. In pasteurizing bottled milk it was found that with the temperature of the water in the vat at from 140 to 150° F. and held for 20 minutes, unsatisfactory bacterial counts were obtained. When, however, the temperature and time of holding of the milk was controlled by a thermometer inverted in a bottle, very satisfactory bacterial reductions were obtained, even when holding only 20 minutes. Temperatures of from 155 to 165° (water vat) gave better results bacterially, but the separation of the cream line was much affected at these temperatures, and a cooked flavor noted. It was found that unless precautions were taken there was danger of water entering the bottles when they were cooled after pasteurization, due to the formation of a partial vacuum in the bottle as the milk contracted on cooling. Tests made on unselected bottles showed that leakage occurred with a very large percentage (44 per cent). The leakage will depend upon the tightness of the cap and the condition of the top of the bottle.

In experiments with three types of ice-cream machines it was found that a large overrun is most easily obtained with the continuous ice-cream freezer, and more rapidly with the horizontal than vertical batch brine freezer. The vertical machine produced the smoothest ice cream and proved most satisfactory for making sherbets and ices.

Pasteurizing milk in bottles and bottling hot milk pasteurized in bulk, S. H. AYERS and W. T. JOHNSON, JR. (*U. S. Dept. Agr. Bul. 240 (1915), pp. 27, figs. 10*).—This material has been previously reported from another source (E. S. R., 31, p. 275).

Leucocytes in milk (*Wisconsin Sta. Bul. 250 (1915), pp. 39, 40*).—Emphasis has been placed on the occurrence of certain streptococci in milk because of the supposed relation of this type of organism to septic sore throat. Eighty-eight animals were examined from four herds and streptococci found by J. M. Sherman in about 40 per cent of the milk samples, although these herds were known from clinical history and appearance to be perfectly healthy. It is therefore concluded that if milk is to be condemned because these chain-cocci are found therein, the product of many healthy animals will have to be eliminated. It is deemed necessary that differential methods should be devised to enable harmful types of such organisms to be separated from the harmless types so frequently found in clean milk from healthy cows.

Do low scores always mean poor milk? F. H. HALL (*New York State Sta. Bul. 398, popular ed. (1915), pp. 11, figs. 2*).—A popular edition of the bulletin previously reported (E. S. R., 33, p. 78).

How to produce cream that makes good butter, O. F. HUNZIKER and G. L. OGLE (*Indiana Sta. Circ. 51 (1915), pp. 8, figs. 7*).—A general discussion of the variations and methods of producing good cream for butter manufacture.

Variations in the tests for fat in cream and skim milk, E. S. GUTHRIE and G. C. SUPPLEE (*New York Cornell Sta. Bul. 360 (1915), pp. 271-289, figs. 9*).—Experiments were conducted to determine the factors affecting the percentage of fat in cream from a centrifugal separator. The milk used was standardized, usually to 4 per cent of fat, and about 40 qt. was used in each determination. All the factors were studied with one machine, and some of them with other styles of machines, five types being employed.

It was found that "the percentage of fat in cream and in skim milk from separators 1 and 2 was affected by low temperatures to a greater extent than was that from the other three types of separators. The tests of the cream from separators 1 and 5 were distinctly variable when there was a difference of ten revolutions of the crank per minute. The other separators were not so affected. The variation of ten turns of the crank did not materially affect the percentage of fat in the skim milk. There is a slight increase in the test of the cream when the inflow of milk is small. The percentage of fat in cream is in almost direct proportion to that in the whole milk. The variation in the amount of whole milk or of the liquid used for flushing does not cause an appreciable difference in the percentage of fat in the cream. The slime deposit does not materially affect the tests of the cream and the skim milk until there is so much that the passages in the bowl become clogged."

The Babcock test and its application, R. E. HUNDERTMARK (*Washington Sta. Popular Bul. 75 (1915), pp. 14, figs. 6*).—General instructions are given for making the Babcock test.

The creamery and testers' license law.—Report of work for the year ending March 31, 1915, O. F. HUNZIKER and G. L. OGLE (*Indiana Sta. Circ. 50 (1915), pp. 36, figs. 9*).—This circular explains some of the provisions of the Indiana law relating to testers' and creamery licenses, describes methods of testing glassware, discusses the effect of factory inspection on equipment and methods used in the Babcock test, treats of the direct benefits derived from the enforcement of the law, and lists the licensed testers and plants for the year.

Markets and prices of Wisconsin cheese, B. H. HIBBARD and A. HOBSON (*Wisconsin Sta. Bul. 251 (1915), pp. 56, figs. 23*).—This bulletin is a continuation of work previously reported (*E. S. R., 29, p. 675*), dealing mainly with Swiss, brick, and Limburger cheese, which constitutes about one-third of that made in the State.

The successive steps from producer to consumer are outlined. More than half of the Swiss, brick, and Limburger cheese factories are cooperative. The organization, equipment, and management of these and the private factories are discussed.

The operations of the Sheboygan County Cheese Producers' Federation, composed of 48 local cooperative cheese factories, are described. It is said that this movement has reduced the wide margin between producers' and consumers' prices comparatively little, but it has sold somewhat more directly, eliminating one middleman and possibly two. In the instances where this advantage has not been offset by increased transportation charges it has meant a lower cost to the retailer and at the same time a price slightly higher to the producer. What the federation has accomplished is to educate the farmers on the subject of marketing. They have learned that the great portion of the middleman charges in marketing cheese are legitimate and, for the present, necessary. Instead of saving several cents by the new method of handling cheese, it

develops that a few eighth-cents are all that can be hoped for until essentially more economical methods are discovered in the manner of distributing the product.

In the brick, Swiss, and Limburger districts most milk is bought by the hundred pounds, regardless of butter fat or casein test. This method is admitted to be unfair, but is said to be preferred by the milk producers. In 1913 the farmer received on an average of from \$1.29 to \$1.33 per 100 lbs. of milk taken to a cheese factory. The cost of manufacturing a pound of cheese is from 1.2 to 1.75 cts. The length of time cheese is stored depends greatly on market conditions. The charge for storing is $\frac{1}{3}$ ct. per pound per month, or from $\frac{2}{3}$ to $\frac{1}{2}$ ct. for the season. In the consideration of marketing cost, the shrinkage of cheese in storage must be taken into account. The amount of this shrinkage during a given time depends on the type, quality, and size of cheese, the temperature, paraffining, wrapping, and time in storage. Data are presented showing the influence of these factors.

Nearly all cheese passes through the hands of one or more middlemen between factory and retailer. The dealer gets a margin of about 1 ct. per pound, the wholesaler about 2 cts., the broker from $\frac{1}{3}$ to $\frac{1}{2}$ ct., and the retailer from 5.5 to 9 cts. The factory, dealers', and wholesalers' prices fluctuate widely during different seasons of the year. The retail price is largely a customary one. The farmer gets about one-half the money paid by the consumer, the remaining half going to pay distributing costs.

In conclusion it is said that "the producers and the consumers are a long way apart. Direct marketing is well-nigh impossible so far as cheese is concerned. The cooperative ownership and management of a cheese factory is of relatively small consequence, although undoubtedly better than any other system, because it solves such a small part of the marketing problem. The long line of middlemen is still intact, and the line is too long. Probably the farmer can not hope to break into the retailer's realm. If that is improved it will have to be by action on the part of consumers. The farmer has therefore at best a hope of effecting savings from but a relatively small part of the total increase in price from factory to consumer. This hope is based very largely on his ability to understand the market and first of all to understand that on himself rests the responsibility of supplying a product of known high quality. In some manner those farmers who produce the high-grade goods should be able to unify their efforts, and by establishing a brand command a higher price for their product than that secured for inferior goods."

VETERINARY MEDICINE.

Annual report veterinary research, 1913-14 (*Union So. Africa Dept. Agr. Rpt. 1913-14, pp. 107-139*).—This report deals first with routine work, which relates largely to inoculations against horse sickness, blue tongue, redwater, etc. Under the heading of research it deals briefly with tuberculosis in hogs, contagious abortion, chick fever in ostriches, pernicious anemia in horses, jagziekte in sheep, and redwater and gall sickness in susceptible cattle. Particular attention is given to investigations of the life history of the ostrich wireworm (*Strongylus douglasii*), and the life history of the sheep scab parasite (*Psoroptes communis ovis*). Under the heading of miscellaneous investigations the report deals with diseases of cattle, effect of dipping working oxen, and dun sickness in horses. A brief report on miscellaneous poisonous plant feeding experiments and a historical sketch of the investigations into lamziekte are included.

Protective enzymes, cytotoxic immune sera, and anaphylaxis, R. M. PEARCE and P. F. WILLIAMS (*Jour. Infect. Diseases*, 14 (1914), No. 2, pp. 351-363).—“On the basis of Abderhalden's theory of protective enzymes and by the use of his dialysis method it has been shown that the serum of a rabbit receiving a single injection of kidney substance develops the power to digest dog's kidney *in vitro*, but has no effect upon the kidney of the dog when administered intravenously. Thus it would appear that the so-called protective enzymes are not to be classed with the immune cytolytins. The digestive power of the serum which develops after the injection of kidney is not limited to the kidney but acts also upon the liver. This is true after one injection or after four or five injections. There is some evidence, however, after multiple injections of a tendency to a more definite effect on the kidney than on the liver.

“A few attempts to demonstrate protective enzymes in the serum of dogs receiving dog's kidney and of animals with experimental nephritis have failed. Attempts to demonstrate protective enzymes in the serum of dogs sensitized to horse serum have not been as successful as those of Abderhalden with the serum of the guinea pig sensitized to egg-white. Negative results have been the rule before shock, and positive results, difficult of explanation, after shock. Dialysis, alone, of small amounts (2 cc.) of serum, obtained either before or five to ten minutes after ‘shock’ in dogs sensitized to horse serum, gives no evidence of the presence of the products of protein disintegration. Larger amounts (10 to 20 cc.) taken $\frac{1}{2}$ to $1\frac{1}{2}$ hours after shock give positive results after dialysis, but the interpretation of these is doubtful on account of the difficulty, under these circumstances, of obtaining serum free of traces of hemoglobin.

“The results of the injection of renal tissues support Abderhalden's general contention concerning protective enzymes, but indicate a lack of specificity. On the other hand, the work with anaphylaxis, while suggestive, is not sufficiently definite to be used in support of the theory that the essential mechanism of anaphylaxis can be explained on the theory of the development of a protective enzyme.

“Finally, the authors state that on account of the many difficulties which the technique of this method presents—and especially because of the frequent presence of ninhydrin reacting substances in the serum of normal animals—thus rendering exact control observation difficult, these results are presented with some hesitation. Moreover, without desiring to detract in any way from the importance of the underlying principle of Abderhalden's theory of protective enzymes as exemplified by his work on pregnancy, we urge caution as to hasty attempts to apply this theory as a general explanation of widely diverse conditions of altered physiology.”

Studies on so-called protective ferments.—I, The sensitization of substratum for the Abderhalden test, J. BRONFENBRENNER, W. T. MITCHELL, JR., and M. J. SCHLESINGER (*Biochem. Bul.*, 3 (1914), No. 11-12, pp. 386-389).—This is an attempt to determine whether the substances brought into play in the Abderhalden reaction are of the nature of antibody, as “antibody” was understood in 1909, or whether they are entirely different.

The result of the work, while it does not seem to furnish definite proof that the nature of defensive ferments is identical with that of the antibody or amboceptor, is nevertheless said to contribute additional evidence to the effect that a certain amount of parallelism between the two apparently exists. In these investigations it was found that “there was not only no dialysis in the containing placenta and the pregnant serum when the temperature was low,

but also that the placenta as well as the serum underwent changes absolutely similar to those we should have expected if we had used, instead, a hemolytic amboceptor and corresponding erythrocytes—namely, the serum was deprived of its property of digesting fresh placenta-protein, and the placenta-protein acquired the property of being digested by any fresh serum. Moreover, such a placenta (sensitized?) could also be digested by serum which was deprived of its specific antibody by exhaustion with placenta in the ice box. . . .

“To those making routine examinations by the Abderhalden method, it is known that the blood of a patient taken under certain conditions, as when there is high temperature, pus formation, or recent ingestion of a meal, may contain an amount of amino acid sufficient to mask the specific reaction. Whereas the last mentioned factor can be regulated with little inconvenience to the patient, blood being taken before breakfast, it is impossible to obviate the complications in the other cases.” A modified procedure is presented which will remove some of the errors in the method.

A note on the preparation of bacterial vaccine, W. J. STONE (*Jour. Amer. Med. Assoc.*, 63 (1914), No. 12, pp. 1011, 1012).—When the bacterial growth is removed from the agar, or other medium, there is a tendency to take with it metabolic products and constituents of the medium. These products are apt to cause a relatively severe local reaction. The author recommends washing all bacterial suspensions and separating them with the centrifuge.

“For purpose of standardization, a suspension of the living, rather than dead, washed organisms is employed. The following method, which is preferable to the blood-cell slide method of Wright because of greater accuracy, was suggested some years ago by Dr. L. H. Spooner of Boston, and has been used by me as a routine procedure with satisfaction: A small amount of the suspension is drawn into an ordinary erythrocyte mixing pipette, diluting 1:100 with a fairly deep colored, thoroughly filtered, aqueous carbolthionin stain (the phenol content is 0.5 per cent). The suspension in the counter is well shaken to secure an even distribution of cells and a small drop placed on the shallow blood-platelet counting chamber of Helber-Zeiss. The organisms in 25 small fields are counted and the sum divided by 25 to obtain unit value. The number so obtained is multiplied by the dilution (100), by 50 (the depth of chamber), by 400 (the number of small squares per cubic millimeter), and lastly by 1,000 to convert to cubic centimeters.”

Some further investigations on the detection of anthrax with the precipitation method, SCHÜTZ and PFEILER (*Arch. Wiss. u. Prakt. Tierheilk.*, 40 (1914), No. 4-5, pp. 395-424).—A continuation of the work previously noted (*E. S. R.*, 25, p. 883; 27, pp. 577, 781; 29, p. 378; 30, p. 682), a larger variety of domesticated animals (bovines, horses, sheep, goats, and pigs) and deer being studied. The extracts of the organs were compared by three methods, viz, boiling (physiological salt solution), chloroform, and Ascoli's modified boiling (acetic acid added to the physiological salt solution extract).

The use of acetic acid as a remover of turbidities in the extract did not seem to have any particular advantage, and after trying other substances, filtration of the extract through dried powdered animal charcoal and filter paper was utilized. Keeping the extract in contact with charcoal for a long time absorbed some of the precipitinogen. In these investigations it was again proved that a chloroform extract of an organ under test gives better results than the ordinary physiological salt (boiled) extract. The latter gave more negative results than the bacteriological examination. The precipitation test was found reliable for detecting anthrax in bovines horses, and sheep, and may also be used for diagnosing anthrax in pigs.

Vaccination against anthrax according to Sobernheim's method, F. ENGEL (*München. Tierärztl. Wchnschr.*, 65 (1914), No. 5, pp. 107, 108; abs. in *Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 33, p. 602).—In all, 274 bovines were treated with serum plus culture subcutaneously. Of this number 3 animals died (after 5½, 9, and 10½ months, respectively). In one establishment where the inoculations were made on November 22, 1911, a newly lactating cow was introduced on December 27 of the same year and this animal died January 9, 1912, from anthrax. The method is considered a good one.

Blood examinations in combating glanders, L. NEVERMANN (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 29, pp. 522-524).—A report of the tests carried out in the pathological institute of the Veterinary High School at Berlin and in the Emperor William Institute in Bromberg from April 1, 1911, to March 31, 1912. Of the 1,635 horses examined, 219 were given autopsy, and 175 of these were found glandered tests. The results obtained in the various districts of Prussia with the agglutination and complement fixation are stated.

The eradication of glanders in Prussia by the blood test, L. NEVERMANN (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 32, pp. 580, 581).—From April 1, 1906, to December 31, 1912, 12,597 horses and 2 mules were tested by the agglutination method. There were 1,786 autopsies made and 1,275 were found glandered. The average percentage of horses destroyed on the basis of the blood test from March 31, 1909, to December 31, 1912, was 91.1.

Vaccination tests with serum against rabies in domestic animals, W. PFEILER and G. KAPFERGER (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6* (1914), No. 4, pp. 284-297; abs. in *Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 33, pp. 602, 603).—As a result of continuing the work previously noted (E. S. R., 30, p. 282) an antirabic serum was prepared from horses. In order to protect against rabies it is necessary to give intraspinal injections of the serum five days before the appearance of the disease in the animals. Curative properties of the serum have not been noted up to date, but it was found that rabid animals treated with the serum lived longer than untreated rabid animals.

The diagnosis of bovine tuberculosis with the complement fixation reaction according to Hammer's method, K. BIERBAUM and G. BERDEL (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 21 (1914), No. 1-5, pp. 249-258; abs. in *Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 30, p. 539).—The antigen in this procedure is an alcohol or acetone extract of the tissue. The procedure is not deemed any more accurate than other methods proposed for the purpose.

The microscopical detection of tubercle bacilli in open tuberculosis of bovines, W. MEYERHOFF (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 31, pp. 551-554).—For the microscopical detection of tubercle bacilli in cases of open tuberculosis in bovines which can not be made to cough by artificial means, the method of Müller, Wiemann, and Jonske must be employed for collecting the sputum. When coughing can be induced Rautmann's method of catching the sputum can be employed.

Sampling lung mucus from bovines for diagnosing open pulmonary tuberculosis, E. SCHARR (*Berlin. Tierärztl. Wchnschr.*, 30 (1914), No. 24, pp. 426, 427).—Instead of the cotton wad recommended in the Scharr and Opalka method (E. S. R., 26, p. 679) silk of a particular texture is recommended, as eliminating some of the disadvantages encountered with cotton.

Some observations on the tuberculin test, W. JOWETT (*Jour. Compar. Path. and Ther.*, 27 (1914), No. 2, pp. 129-151, figs. 8).—The purpose of this work was to determine the value of the so-called local tuberculin tests and also of the associated tuberculin tests. The first experiments were made with a few tuberculous animals, and subsequently the results obtained on these animals

were used as a guidance in tests conducted on other animals, imported and otherwise.

The subcutaneous test is discussed in a very comprehensive manner and the following facts are emphasized: "In some animals, especially in case of overfat, recently imported 'show' cattle, as also in cows and heifers advanced in pregnancy and those in which parturition has recently occurred, the body temperature is liable to show variation from day to day of 1 to 2° F. or more. Not all tuberculous cattle respond thermally to the subcutaneous tuberculin test. Even amongst those animals which are capable of giving a febrile reaction in response to the injection of tuberculin the highest temperature recorded after inoculation may fall below 104°, and if such animals are retested, even with a double dose of the same stock tuberculin, after an interval of only one month, the chances in favor of their nonreaction are greater than of their reaction."

Tuberculin loses some of its properties when stored under unfavorable conditions or in a diluted state. It is not strictly correct to assume that animals injected with tuberculin will not show a local swelling such as is observed with the mallein test in a glandered animal. These phenomena, although not constant, sometimes occur and one should be on the lookout for them, especially when retesting doubtful reactors. The swellings may vary in size but they are at times as large as the palm of one's hand. They are most often evident in thin-skinned animals and those in somewhat poor condition.

The conjunctival-, ophthalmic-, or oculo-tuberculin reaction when conducted simultaneously with the subcutaneous test does not give a marked reaction. It is better to make the conjunctival test shortly before or some four or five days after the subcutaneous test. One may, however, apply the intradermal test simultaneously with the conjunctival test with excellent results. Good results may be obtained by submitting the animals to a conjunctival test the day previous, or even twelve hours or so before applying the subcutaneous test. The author is not inclined to concur in the belief of some workers that a previous subcutaneous test does not influence in any way or prevent a subsequent conjunctival reaction, as animals do not acquire a tolerance against the conjunctival test. A tuberculous animal previously submitted to the conjunctival test will after a few days when given a subcutaneous injection of tuberculin show a secondary reaction in the eye. This was noted in a minority of the subjects.

The intradermal test (E. S. R., 30, p. 883) was tried on upwards of 225 animals. The results were controlled in every case by a later subcutaneous test, and whenever possible the animals were slaughtered and submitted to a careful post-mortem examination. "The subjects of the experiments comprised calves, bulls, cows, heifers, in fact all classes of bovines, some being known tuberculous animals which were purchased for the purpose of experiment, others being doubtful reactors to the subcutaneous tuberculin test, whilst a large number were imported or colonial cattle, the former history of most of these being unknown. Briefly, the intradermal test has given very satisfactory results and has proved, to the satisfaction of the writer, its utility as a diagnostic method. It is not claimed that the intradermal test is superior to the ordinary subcutaneous (tuberculin) test, but in the writer's opinion the first-mentioned test is very nearly, if not quite, equal to the latter as a diagnostic method; moreover, it possesses a number of advantages over the subcutaneous method."

A remedy for clover bloat, D. J. HEALY and J. W. NUTTER (*Breeder's Gaz.*, 67 (1915), No. 25, p. 1198).—The occurrence of bloat in the Kentucky Experiment Station dairy herd following the consumption of clover led the authors to experiment with a view to discovering an efficient remedy therefor.

Analyses showed that red clover blossoms contained sugar to the extent of 3.6 per cent, alfalfa blossoms 2.8 per cent, and white clover blossoms 2.4 per cent, whereas in the blossoms of blue grass and in the leaves of clover and alfalfa the quantity of sugar present was found to be less than 1 per cent. In the test with fermentation tubes it was found that when white clover blossoms were thoroughly ground and mixed with a quantity of sterile distilled water and held at a temperature of 37° C. for 24 hours an active fermentation took place; at the end of this period the quantity of carbon dioxide gas which had been formed equaled 45 per cent of the volume of the original clover blossom mass.

The bloated condition of the animals was alleviated through the use of a solution of formaldehyde as a drench. In two cases in which formaldehyde was administered the cows refused their dry feed and suffered diminished milk production for a period. The authors have demonstrated that under laboratory conditions urotropin will act as efficiently as formalin, although it requires a somewhat larger dose. For the present they strongly recommend the use of 1 qt. of a 1.5 per cent solution of formalin, followed by the placing of a wooden block in the animal's mouth and gentle exercise if the animal can be gotten up.

Thiele's hog cholera remedy "544" (*North Dakota Sta. Spec. Bul.*, 3 (1915), No. 17, pp. 289-291).—A test made by Dr. Paul Fischer, of the bureau of livestock industry of the State of Ohio is briefly noted. Either 8 or 9 pigs were used in each test, all belonging to the same litter. All pigs received 2 cc. of hog-cholera virus, some either antihog-cholera serum or Thiele's "544" in addition, and some were kept as checks. The pigs receiving "544" died on almost precisely the same days as the checks, or in some cases a little earlier.

Poultry diseases (*Wisconsin Sta. Bul.* 250 (1915), p. 40).—In the course of investigations by B. A. Beach, H. E. Lothe, and J. G. Halpin of an outbreak of a disease from which nearly 2,000 chickens died in less than 10 months, a bacillus was isolated which caused death in five or six days when introduced beneath the skin of healthy fowls. This organism, in many respects resembling the bacillus causing fowl cholera but differing in that it does not affect ducks, is believed to be present in addition to those causing roup or chicken pox in the outbreaks with excessive mortality. A vaccine is said to have been prepared which will render a fowl immune to the disease. See also a previous note (E. S. R., 31, p. 887).

Some factors in combating fowl tuberculosis, L. VAN ES (*Berlin. Tierärztl. Wechschr.*, 30 (1914), No. 32, pp. 575, 576).—A detailed discussion of the etiology of tuberculosis in fowls, as well as of the predisposing causes, and the means for controlling the disease. See also a previous note (E. S. R., 31, p. 582).

RURAL ENGINEERING.

The use of water in irrigation, S. FORTIER (*New York: McGraw-Hill Book Co.*, 1915, pp. XIII+265, pls. 10, figs. 71).—This volume deals with the agricultural side of irrigation. It is intended for the use of new settlers in the West, irrigation farmers and those who are interested in irrigated agriculture, and students in agricultural high schools and in agricultural and engineering classes of colleges and universities.

The subject matter is confined almost exclusively to the irrigated farm and to the problems confronting the irrigator. The legal, economic, and engineering phases of the subject are touched upon, but only in so far as they affect the welfare of the farmer. The subject matter is presented under the chapter headings of the irrigated farm, the necessary equipment and structures, methods of preparing land and applying water, waste, measurement, delivery, and duty of water, and irrigation of staple crops.

"Considerable space has been given to methods of preparing land and applying water, for the reason that the manner in which these are done determines to a large degree the profits derived by the farmers and the success of canal companies. . . . The manner in which water is used in irrigation as described in these pages is nation wide. The same care and attention which were paid to the irrigation of cotton and sugar cane in the Southwest, to rice in the Gulf States, and to truck and fruit crops along the Atlantic seaboard were given to the irrigation of forage and cereal crops in the mountain States and to vineyards and orchards along the Pacific."

The author states that the contents of this publication are drawn in the main from the publications and work of the Irrigation Investigations Division of this Department.

Treatise on engineering studies and works for water transportation, H. ENGELS (*Handbuch des Wasserbaues für das Studium und die Praxis. Leipzig: W. Engelmann, 1914, pp. XII+1499, figs. 1623; rev. in Engin. News, 73 (1915), No. 3, pp. 116, 117.*)—This book, in two volumes, contains, in addition to several sections giving a large amount of general hydraulic engineering information and working data, a section treating of agricultural hydraulics, especially drainage and irrigation. Sections of the pumps used for drainage purposes in the Holland polders and elsewhere are given and tide gates are described. The reclamation and cultivation of peat lands are also considered.

Report of the state engineer, A. J. PARSHALL (*Bien. Rpt. State Engin. Wyo., 12 (1913-14), pp. 201, pls. 16.*)—This reports the activities of the state engineering force during the years 1913 and 1914, which included, among other work, irrigation and stream gaging.

[**Irrigation and other experiments, Umatilla project, Oregon, 1914**], **R. W. ALLEN** (*U. S. Dept. Agr., Bur. Plant Indus., Work Umatilla Expt. Farm, 1914, pp. 1-8, fig. 1.*)—Climatic and agricultural conditions on the project are described briefly, including the results of measurements of precipitation, evaporation, wind velocity, and temperature, and irrigation experiments to determine the most economical methods of handling water are reported.

It was "found that upon virgin land without crops a 2½-in. application of water is retained in the first 4 ft. of soil. Five in. of water applied under identical conditions filled the first 10 ft. to its full carrying capacity and part of the water passed even below this depth. Twenty-four hours after 5-in. and 10-in. applications of water were made on two plats having the same kind of soil there remained an equal quantity of water in each plat to the depth of 4 ft., and this quantity was practically the same as was retained by the same layer of soil where a 2½-in. irrigation was applied. On land of a finer texture and bearing a crop of alfalfa, a 4-in. application of water was all held in the upper 4 ft. This shows that in either case heavy losses result from applying heavy irrigations to the lighter soils of this project. . . ."

"The frequency of applying water had a very marked influence upon crop yields. A plat of alfalfa given 4.4 ft. of water at eight applications yielded 4 tons of hay. . . . Another plat given 5.3 acre-feet applied in twelve irrigations yielded 5.3 tons. . . . A third plat given 9.7 acre-feet of water in twenty-four irrigations yielded 5.57 tons. . . . Thus, the best results were obtained from 5.3 acre-feet of water applied in twelve irrigations. . . ."

"To get the greatest benefit from irrigation water on these sandy soils it should be very carefully handled. The necessity for economical use requires that special emphasis be placed on (1) using short irrigation furrows, ranging from 100 to 200 ft. in length, (2) making irrigation furrows 20 to 30 in. apart, (3) using fairly shallow furrows, well opened, to facilitate the flow of water,

(4) running water for but a short time in one place, as loss soon occurs from deep percolation, (5) the use of a small amount of water for each irrigation, since the storage capacity of the soil is very low, (6) the frequent application of water to maintain an adequate supply for plant growth, as the small quantity that it is possible to store in the soil is quickly taken up by the plants or evaporated, and (7) using a comparatively large stream of water while irrigating, in order to cover the land as quickly as possible."

Irrigation of the plains of Kep, Voi, Bao-Loc, Pins, and Phu-Lang-Thong, ROUEN (*Bul. Écon. Indochine, n. ser., 17 (1914), No. 109, pp. 517-540, pl. 1*).—This article describes the irrigation works, including dams, storage reservoirs, canals, etc., and reports briefly the general results obtained in the irrigation of rice. It is stated that the net benefit realized from the irrigation of rice in Kep has amounted annually, in round numbers, to about \$38 per hectare (\$15.40 per acre), thus justifying the extension of the irrigation works.

Water regulation in the different water districts of Java and Madoera (*Verlag Burgerl. Openb. Werken Nederland, Indië, 1911, pt. 4, B. Bijlage II, pp. 11+174*).—This report covers developments in irrigation, the distribution and use of irrigation water, conveyance and diversion of water, and water regulation.

Surface water supply of Missouri River basin, 1913 (*U. S. Geol. Survey, Water-Supply Paper 356 (1915), pp. 291, pls. 2*).—This report, prepared in cooperation with the States of Montana and Nebraska, presents the results of measurements of flow made on the Missouri River and its tributaries during 1913.

Surface water supply of the lower Mississippi River basin for 1913 (*U. S. Geol. Survey, Water-Supply Paper 357 (1915), pp. 86, pls. 2*).—This report, prepared in cooperation with the State of New Mexico, presents the results of measurements of flow made on the Arkansas, Yazoo, Red, and Canadian river basins in the lower Mississippi River basin in 1913.

Water resources of the Rio Grande basin, 1888 to 1913, including surface water supply of the western Gulf of Mexico basins, 1913, R. FOLLANSBEE, H. J. DEAN, ET AL. (*U. S. Geol. Survey, Water-Supply Paper 358 (1915), pp. 725, pls. 3*).—This report describes the general features of the Rio Grande basin and presents the results of measurements of stream flow made in the basin and in the western Gulf of Mexico basins. The results of studies of precipitation, evaporation, and sedimentation as factors in determining the value of reservoir sites for the storage of flood waters are also presented.

Report of progress of stream measurements for the calendar year 1913, P. M. SAUNDER, G. H. WHITE, and G. R. ELLIOTT (*Dept. Int. Canada, Sess. Paper 25c (1914), pp. V+414, pls. 20*).—This report presents the results of measurements of flow made on streams and irrigation ditches in Alberta and Saskatchewan during 1913.

Pumping water by means of steel windmills, B. MÜLLER (*Fördertechnik, 7 (1914), No. 13, pp. 161-167, figs. 15; abs. in Wasser u. Abwasser, 9 (1914), No. 1, pp. 9, 10*).—This article gives considerable tabular data regarding wind velocities, wind power, power of windmills for pumping purposes, and data to be used in determining the size and location of the windmill and the size of suction and pressure pipe for pumping under certain given conditions, especially from deep wells. In comparative tests of windmill power and electrical and gas engine power for meadow draining in east Prussia, using a vertical submerged centrifugal pump, it was found that the expense of operation over a long period of time was much the least with wind power, followed in order by electrical and gas engine powers.

Irrigation with fresh water from the sea, E. J. MOYNIHAN (*Sci. Amer. Sup.*, 79 (1915), No. 2040, pp. 84, 85).—The author proposes the use of sea water for irrigation purposes and maintains that its distillation to remove the injurious salts is practicable.

He describes two methods of procedure, the first of which is based on the fact that the temperature of sea water varies considerably with the depth and that probably "for those months in the year in which water is most needed there are suitable places near shore where a temperature difference of 5° exists in very moderate depths of water . . . Under these conditions it is easy to evaporate the water at the higher, and to condense it at the lower, temperature.

"The second method of distilling the water consists of increasing the pressure and therefore raising the temperature of the distilled vapor or the water to be distilled by mechanical means, such as a compressor turbine, and condensing the vapor in a surface condenser, the condensation water being the same water that is being evaporated. In this way the whole of the latent heat of condensation is returned to the water which is being condensed."

Proceedings of the tenth annual meeting of the Iowa State Drainage Association (*Proc. Iowa State Drainage Assoc.*, 10 (1914), pp. 93).—These proceedings contain the following special articles:

Drainage Conditions in the Province of Manitoba, by F. G. Churchill (pp. 11-13); What the Drainage Investigations of the U. S. Department of Agriculture Are Doing for Farmers in the Humid Regions, by F. F. Shafer (pp. 13-22); An Investigation Into the Efficiency and Equity of Present Methods of Levying Assessments for Drainage Benefits, by J. W. Lee (pp. 26-32); Drainage Assessments and Their Relation to the Farmer, by M. L. Henderson (pp. 33-37); Mutual Interests of Drainage Organizations and Highway Organizations, by J. H. Ames (pp. 39-42); Standard Methods of Testing Drain Tile and Sewer Pipe, by A. Marston (pp. 43-46); Tile Testing Machine Demonstration—Demonstration of Ditching Machine (pp. 46, 47); The Maintenance of Small Drainage Ditches, by S. Dean (pp. 47-50); Minnesota Drainage Commission, by J. T. Stewart (pp. 52-58); Problems of a Drainage Contractor, by J. A. Dunkel (pp. 59-64); The Possibilities for Experimental Work in Drainage Investigations, by W. J. Schlick (pp. 64-68).

Alkali and water-logged lands (*Salt Lake Com. Club Bul.* 1 (1914), pp. 30, figs. 11).—This bulletin contains the following special articles: The Soils of Salt Lake County, by R. Stewart; Redeeming Alkaline Lands, by E. D. Ball; Drainage of Alkali Lands, by L. A. Merrill; Drainage a Factor in the Future Growth of Salt Lake City, by R. A. Hart; and Tile Drainage in the Reclamation of Water-logged and Alkaline Lands, by J. C. Wheelon.

West Tennessee gullied lands and their reclamation, R. S. MADDOX (*Resources Tenn.*, 5 (1915), No. 1, pp. 8-22, figs. 3).—This article deals with an area of more or less eroded and gullied lands lying in a belt extending in a northeast and southwest direction through the State, and which is practically contained in the counties of Henry, Benton, Carroll, Henderson, Madison, Chester, McNairy, Hardeman, and Fayette.

It is stated that in this area more than 115,000 acres of land once cultivated are now occupied or influenced by gullies and that over 230,000 acres once cleared and cultivated are lying waste. The soil in this belt is very sandy and in some localities is mixed with enough clay to make it subject to easy erosion.

For starting the reclamation of these lands the author recommends the planting in gullies of such quickly-growing and widely-rooting trees as the black locust, yellow poplar, black walnut, and sycamore, and such crops as Japan clover, wild honeysuckle, and Bermuda grass. All these are said to be particu-

larly adapted for stopping up gullies and for the protection of lands which tend toward gullying. It is pointed out in this connection that the soil in the bottoms of gullies is usually sufficiently fertile for the growing of the above-mentioned plants.

The law of highways, W. W. MACKENZIE (*London: Butterworth & Co., 1911, 16. ed., pp. CXIV+1252*).—This is the sixteenth edition of this book, covering English laws in regard to highways, main roads, streets, and bridges. It is divided into two sections, the first dealing with the law of highways independent of statute and the second with statutes relating to highways, main roads, streets, and bridges.

The chapters under the first division are highways in general; dedication of highways; ownership of the way; repair and nonrepair of highways and bridges, and remedies for nonrepair; obstructions and nuisances; and extinguishment and diversion of highways. Under the second division the chapters are highways, main roads, and streets; locomotives on highways; highways interfered with by railways; tramways on highways; and bridges.

Report of the state commission of highways (*N. Y. Rpt. State Com. Highways, 1912, pp. 694, pls. 26*).—This is a report of the activities of the commission during the year 1912.

Road models (*U. S. Dept. Agr. Bul. 220 (1915), pp. 24, pls. 13, figs. 2*).—This is a revision of Bulletin 47 of the Office of Public Roads of this Department, previously noted (*E. S. R., 28, p. 890*).

Surfaces or floors for bridges, C. OLDER (*Good Roads, n. ser., 9 (1915), No. 6, pp. 60-63, figs. 9*).—The author relates the results of his experience regarding floors for highway bridges and concludes that ordinary plank floors having an average life of not more than three and one-half years are to be avoided when possible.

“With the exception of the floor with the bituminous surface, the cost of the floor increases as the weight decreases, and yet the cost of the entire superstructure decreases as the weight of floor decreases. The saving in cost for the lighter floors increases with an increase in the unit cost of structural steel in place, and decreases with an increase in the cost of the materials used in such floors. In reflooring old steel bridges of satisfactory design, a creosoted subplank with bituminous wearing surface has been found to give reasonable service. . . . The cost of maintaining the bituminous surface is only about 20 per cent of that of an ordinary plank floor. There seems to be no place in the economic design of new highway bridges for floors consisting of a creosoted plank subfloor with a brick wearing surface.”

Use of the Abney hand level, T. F. HICKERSON (*N. C. Geol. and Econ. Survey, Good Roads Circ. 99 (1914), pp. 6, figs. 7*).—This circular describes a hand level, for use in road engineering, which not only gives a level but also an inclined line of sight by means of a vertical arc graduated in degrees and minutes and a vernier reading to five minutes.

RURAL ECONOMICS.

Principles of rural credits, J. B. MORMAN (*New York: The Macmillan Co., 1915, pp. XVIII+296*).—The author describes the methods of financing farmers in European countries, indicating how the different forms of credit are made available to them. He claims that the first step for placing rural credit on a firm basis in the United States and Canada is the organization of farmers into cooperative societies. This should be brought about not only by the farmers themselves, but encouraged by state and national laws. With a view to their

future federation the cooperative organizations should have as much uniformity as possible in their rules and regulations. It is considered essential that the association should select and determine the character of its own membership, that it should limit the amount of stock any member may hold, that no member should have more than one vote, and that the profits, if any, should be distributed to the members on the basis of the amount of business transacted by each with the organization or should be held as a reserve fund against the possibility of future losses.

The second step is the protection of the farmers against usurious conditions; the third, the granting by the State of long-time loans to farmers on first mortgages at reasonable rates of interest and on the amortization plan of repayment; the fourth, the adoption of a more rational and less expensive system of land registration; and the fifth, an educational propaganda by the national government on the principles of cooperation and on the proper use of credit.

Agricultural organizations in European countries, R. A. PEARSON (*N. Y. Dept. Agr. Bul. 66 (1914), pp. 451-636, pls. 47*).—The author, in describing those features of agricultural organization which are adaptable to American conditions, points out that the success of cooperative efforts is in proportion to the need of them as well as to the efficiency with which they are carried out. An examination of foreign cooperative organizations shows that the effort is constantly made to prove by reasoning and by practice that cooperative buying and selling by farmers is not detrimental to legitimate business interests, but no effort is made to conceal the fact that those societies are distinctly injurious which thrive on unreasonable profits. He considers the importance of putting the responsibility directly upon the individuals who compose the society, as this insures the personal interest and activity which are necessary to success. Any effort made by the nation or State to assist in cooperation must carefully avoid the removal of this important personal incentive.

[**Cooperation in Switzerland**] (*Pubs. Sec. Suisse Paysans, No. 49 (1913), pp. 87*).—This is the seventh annual report relating to cooperative organizations, and indicates the membership by types of societies and principal activities during the year 1913.

The social anatomy of an agricultural community, C. J. GALPIN (*Wisconsin Sta. Research Bul. 34 (1915), pp. 34, pl. 1, figs. 10*).—This bulletin outlines the methods used by the author in making a social survey of Walworth County, Wis., describes and discusses conditions as found by him, and gives a number of maps indicating the extent of the various influences in the villages and cities upon the surrounding rural districts. The author concludes from his studies of these maps that the farm people on the land are situated upon the slopes of social watersheds draining into one specific village or small city; that these social watersheds ignore township and county lines; therefore it is difficult to get people who belong to different social basins, whose paths constantly lead over different roads toward different civic centers to work together aggressively under a township plan in regard to matters which belong naturally only to the homes that move together in the larger affairs of ordinary life. This maladjustment of local government is deemed perhaps the fundamental handicap of the farm home. The readjustment of rural populations into communities, steps in replanning a comprehensive community, and evidences of an alliance between town and farm are discussed with a view to alleviating such conditions.

[**The dwellings of agricultural workers**], R. DURAND and J. SÁNCHEZ (*Bol. Mens. Musco Soc. Argentino, 4 (1915), No. 37-38, pp. 75-103, figs. 17*).—The articles written by the above authors relate to housing conditions as found among different types of agricultural people in Argentina.

A report on public administration in relation to agriculture and allied interests, J. W. GARNER (*Chicago: Effie. and Econ. Com., 1914, pp. 51*).—This report calls attention to the fact that in Illinois the state boards and offices for the administration of laws relating to agricultural interests have been entirely independent of one another and not correlated in their activities. The committee advises that the various boards and offices be brought together in a single department with one administrative head.

Negroes in the United States (*Bur. of the Census [U. S.] Bul. 129 (1915), pp. 207, figs. 21*).—There has been brought together in this one bulletin the greater part of the statistical information of the census relating to the negroes. Among the statistical tables are those that show for rural districts the number of negroes and the school attendance by age periods, number of voting age, marital condition and illiteracy and ownership of farm homes, number engaged in agriculture by sex, number of farms, total and improved acreage, and tenure and value of farm property. This information is given for the individual States and for groups selected because of their relation to the negro problem.

Live stock [in Costa Rica] (*Internat. Inst. Agr. Rome, Bul. Agr. and Com. Statis., 6 (1915), No. 2, p. 79*).—The number of live stock in Costa Rica is reported for 1914 as follows: Cattle, 336,061; horses, 52,095; pigs, 63,552; mules, 2,469; asses, 107; goats, 522; sheep, 122.

Agricultural statistics of Sweden (*Statis. Årsbok Sverige, 1915, pp. 60-75*).—Statistical data are given for 1913, showing by departments the area of land devoted to different agricultural purposes; the area, total production, average yield and value of the principal crops; the number of live stock, and the production of dairy products. For many items comparative data for the country as a whole are shown.

Agriculture in Algeria (*Statis. Gén. Algérie, 1912, pp. 233-280*).—These pages of the annual report contain statistical data showing the area in crops, number of agricultural implements, number of operators by tenure, and number of live stock.

[Agricultural statistics of Egypt] (*Ann. Statis. Egypte, 6 (1914), pp. 319-370*).—These pages of the annual report give the number of farm operators, the area in farms by size, the area cultivated and not cultivated, the area in the principal crops, the number of live stock, and the trade in the principal agricultural products. The data are for 1913 and by minor subdivisions, with comparative data for earlier years for the more important items.

[Chinese agriculture] (*China Year Book, 1914, pp. 47-59*).—These pages of the annual report give, for the principal agricultural products grown, a brief statement concerning the localization of the crops, the domestic and foreign trade, and the uses to which they are put.

[Agriculture in Japan] (*Statis. Rpt. Dept. Agr. and Com. Japan, 30 [1913], pp. 836, pls. 3*).—These pages continue the statistical data previously noted (*E. S. R., 31, p. 491*) by reporting information for 1913.

[Agriculture of New Zealand] (*New. Zeal. Off. Yearbook 1914, pp. 506-620, pls. 2*).—These pages of the annual report relate to land tenure, settlement, land transfer, occupation and ownership of land, area and yield of crops, and number of live stock.

Monthly crop report (*U. S. Dept. Agr., Mo. Crop Rpt., 1 (1915), No. 2, pp. 8*).—This number contains estimates as to the condition of a large number of crops on June 1, 1915, and of cotton on May 25, 1915, by States, with comparisons for earlier years, and as to the farm value of many important products on May 15 and of others on June 1, together with data as to the range of prices of agricultural products at important markets, and miscellaneous data. It also

contains a series of diagrams, indicating by States the period of wheat harvest, corn and oats planting, and of planting and picking cotton.

The revised estimate of the 1914 cotton acreage is given as 37,406,000 acres. The estimated number of bushels of apples carried on railroad lines representing four-fifths of the total United States mileage and on practically all the boat lines from June 1 to November 30, 1914, is 45,066,000.

Statistical notes on the production, imports and exports, prices and maritime freights of cereals (*Internat. Inst. Agr. Rome, Bul. Agr. and Com. Statis., 1915, Mar., Sup., pp. 47*).—There have been brought together in this report statistical data showing the world's production of wheat, rye, barley, oats, maize, and rice in order to determine whether the cereal harvest of 1914-15 is sufficient to meet the average world consumption until the time of the next harvest. The harvest for the individual countries and the world as a whole is shown for 1913-14, with comparative data for the five and ten year periods preceding. The study seems to show that the world's crop of wheat, rye, and maize exceeds the quantity necessary for consumption, while there is a deficit of barley and oats.

[Prohibited exportation of agricultural products] (*Internat. Inst. Agr. Rome, Bul. Agr. and Com. Statis., 6 (1915), Nos. 1, pp. 23-26; 2, pp. 80-84; 3, pp. 124-128; 4, pp. 171-173*).—There are briefly outlined the restrictions placed upon the exportation of agricultural products by different countries because of the war situation.

AGRICULTURAL EDUCATION.

[Progress in agricultural education in Manitoba] (*Rpt. Dept. Agr. and Immigr. [Manitoba], 1913, pp. 15-21, 85-89, pls. 2*).—This report contains the eighth annual report of the board of directors on the progress of the Manitoba Agricultural College, and a report on the agricultural societies and college extension work for 1913 dealing with agricultural society fairs, agricultural and arts associations, agricultural special trains, boys' and girls' clubs, good farming competitions, home economics societies, seed fairs, short courses in agriculture, standing grain competitions, and plowing matches.

Report of the department of agriculture for 1912 (*Landtbr. Styr. Meddel. [Finland], No. 89 (1912), pp. 222+28*).—This is a report on the work of the department of agriculture, the agricultural education and research institutions, societies, and experts for the advancement of Finnish agriculture.

The use of land in teaching agriculture in secondary schools, C. COLVIN (*School Sci. and Math., 15 (1915), No. 4, pp. 329-333*).—The author suggests how land may be used by the city high school having little land, the township high school having a medium plat of ground, the high school having access to or owning a large farm, and the academy operating a farm.

Tenth acre gardening demonstration, E. KIRKPATRICK (*Iowa Agr., 15 (1915), No. 7, pp. 423, 424*).—A cooperative experiment was carried out during the past year by the departments of agricultural education and horticulture of the Iowa State College on a tenth-acre plat of comparatively rich soil without special preparation or the use of fertilizers or irrigation to test to what extent school gardening pays. The returns from the garden showed a profit of \$25. Tomatoes proved to be the most paying crop in proportion to space planted.

Agricultural extension service (*Wisconsin Sta. Bul. 250 (1915), pp. 53-96, figs. 20*).—An account is given of the activities of the extension service, which is organized into the following main groups: (1) Departmental extension, which is largely demonstration work carried out mainly under field conditions; (2) the county agricultural representative system, in which resident instructors

are located in the several counties for educational work, mainly along demonstration lines; (3) the combined or collective activities of two or more departments presented mainly through the medium of extension courses, schools, educational trains, exhibits, etc.

[Agricultural and home economics instruction in the public schools of New Hampshire], G. H. WHITCHER (*N. H. Dept. Pub. Instr., Inst. Circs. 1914-15, Nos. 2, pp. 4; 12, pp. 18; 17, pp. 6; 18, pp. 15; 20, pp. 3*).—These circulars offer suggestions to domestic arts teachers starting the first course in cooking, on household appliances having to do with heating, ventilating, sanitation, food storage, and sewage disposal, and on the tomato project for domestic arts classes; and to agricultural teachers in secondary schools on beginning project work in the spring.

[Instruction in agriculture, cooking, and sewing in Porto Rico] (*Rpt. Comr. Ed. P. R., 1913, pp. 334-338*).—This is a report on the status of instruction in agriculture, cooking, and sewing in the public schools of Porto Rico in 1912-13.

Education for the home, B. R. ANDREWS (*U. S. Bur. Ed. Buls. 1914, Nos. 610, pp. 53, pls. 6; 611, pp. 207, pls. 10; 612, pp. 109, pls. 10; 613, pp. 61*).—This is a comprehensive report on the present status of education for the home, arranged in four parts, viz. (1) an introductory survey of certain of the findings and a discussion of equipment for teaching household arts in elementary, high, and normal schools and colleges; (2) state legislation and provisions for education for the home and the work of the rural, elementary, high and normal schools, technical institutes and special institutions, and other agencies and organizations in the home betterment movement; (3) organization of home economics instruction in the various colleges and universities; and (4) a list of references on education for the home, and a list of cities and towns teaching household arts.

Cooking in the vocational school as training for home making, I. P. O'LEARY (*U. S. Bur. Ed. Bul. 625 (1915), pp. 36, pls. 2, figs. 4*).—This bulletin discusses the conditions which underlie the necessity for instruction in cooking, defines the aim of such instruction, and offers suggestions toward the final solution of the problem under the following topics: Home making as a vocation for girls, regular school methods and "trade" training in cooking, markets for the product, part-time classes for housekeepers, taking instruction to the pupil, and the kitchen and its equipment, including plans and price list of equipment and utensils.

Lesson plans for teachers in nature-study agriculture, ALICE J. PATTERSON and LORA M. DEXHEIMER (*Bloomington, Ill.: Authors, 1914, pp. 166*).—These lessons, which are based upon the Illinois state course of study and are arranged in monthly sequence for the eight years of the grammar grades, deal with birds, trees, flowers, garden plants, farm crops, and animals, including poultry, insects, weeds, soils, farm machinery, good roads, dairying, physiology, etc. In addition to the necessary fundamental facts they offer suggestions on how to obtain material, what to have the children observe, how to report the observations, how to conduct simple experiments, etc.

[Rural school agriculture] (*Univ. Minn., Dept. Agr., Rural School Agr. 4 (1914), Nos. 3, pp. 8, figs. 2; 4, pp. 8, figs. 3; 4 (1915), Nos. 5, pp. 8, figs. 2; 6, pp. 4, figs. 2*).—These circulars include a study of legumes, wheat, and alfalfa, an outline for an illustrated corn booklet, a report of boys' and girls' club work for 1914, and directions for organizing pig clubs in 1915.

Practical lessons in tropical agriculture, Book I, R. L. CLUTE (*Yonkers, N. Y.: World Book Co., 1914, pp. X+228, figs. 180*).—This text, for pupils in the Philippine schools, treats of the plant and its parts and practical applications of the laws governing plant life, each chapter being followed by demonstra-

tion exercises. An appendix gives directions for making a balance and rain gauge and a list of agricultural literature.

Soils and fertilizers for public schools, C. L. QUEAR, edited by O. L. BOOR ([*Muncie, Ind.*]: *Author*, 1915, pp. X+202, figs. 83).—This text, which is designed for the average district or graded school, includes chapters on the conditions necessary for plant life, soil formation, classes, improvement, moisture, drainage and tillage, elements valuable in fertilizers, natural and artificial fertilizers, the hotbed and water supply, and studies in concrete. These are followed by experiments, directions for making agricultural apparatus, review questions and problems, and references to the literature.

Potato growing, W. D. HURD (*Mass. Agr. Col., Dept. Agr. Ed. Circ. 31* (1914), pp. 23, figs. 12).—This circular for the members of boys' and girls' clubs describes the various operations and methods in growing potatoes.

Rice judging and study, J. C. RUNDLES (*Philippine Agr. and Forester*, 3 (1915), No. 8, pp. 181-190).—An outline prepared by the College of Agriculture of the Philippines is given for the study of different varieties of rice, together with exercises in seed selection and vitality tests, a score card, and its explanation, for rice in the hull.

Productive vegetable growing, J. W. LLOYD (*Philadelphia: J. B. Lippincott Co.*, 1914, pp. XIII+339, pl. 1, figs. 193).—This book is written primarily as a text for use in schools and colleges, from the viewpoint of conditions in the corn belt, but the principles laid down are applicable in all sections. The aim has been to emphasize principles rather than mere details of practice. Temperature requirements of the different crops are made the basis of the classification of vegetables and given special prominence in the cultural directions for the various crops. A chapter is devoted to suggestions for laboratory work, and an appendix gives the chemical composition of vegetables.

Suggestions to teachers of fruit growing in the high schools, C. S. WILSON (*Cornell Countryman*, 12 (1915), No. 5, pp. 391-393).—The author discusses the adaptation of subject matter in fruit growing to the needs of high school students, and gives an outline of topics under the subject of pruning, indicating those suitable for use in the high school.

MISCELLANEOUS.

Twenty-sixth and Twenty-seventh Report of Rhode Island Station, 1913 and 1914 (*Bul. R. I. State Col.*, 10 (1915), No. 4, pp. 23-27, 30-32).—These pages include a report of the director for the period from June 30, 1912, to December 31, 1914, on the work, publications, and personnel of the station, and a financial statement for the fiscal year ended December 31, 1914.

Annual Report of South Dakota Station, 1913 (*South Dakota Sta. Rpt.* 1913, pp. 38).—This contains a report by the director on the organization, work, and publications of the station, a list of exchanges, a financial statement for the fiscal year ended June 30, 1913, and departmental reports, portions of that of the agronomist being abstracted on pages 321 and 331 of this issue.

Report of the director, 1914, H. L. RUSSELL (*Wisconsin Sta. Bul.* 250 (1915), pp. 109, figs. 49).—This contains the organization list, a report of the work of the station during the year, portions of which are abstracted elsewhere in this issue, brief summaries of the publications of the year, and a financial statement for the federal funds for the fiscal year ended June 30, 1914.

NOTES.

Arkansas University and Station.—J. H. Miller, dean of the extension division at the Kansas College, has been appointed dean of the extension service beginning July 14. W. C. Lassetter will continue as director of agricultural extension. A special effort is to be made to carry the benefits of the station work to the farmers through the agency of the extension workers, looking to the station as authority for facts in the instruction placed before the farmer.

H. A. Sandhouse, of the Colorado College, has been appointed assistant in animal husbandry, vice D. H. Branson, who resigned July 1 to take up graduate work. G. W. Hervey, of Rutgers College, has been appointed assistant in animal husbandry for special poultry work, beginning August 1. George L. Caldwell has been appointed assistant in veterinary science, beginning September 1, and will also assist in research work in bacteriology.

Florida University and Station.—At the recent session of the legislature \$16,500 was appropriated for the station during the biennium, \$5,000 being for maintenance, \$4,000 for repairs and fixtures, and \$7,500 for printing.

Director P. H. Rolfs of the station has been made dean of the college of agriculture, beginning July 1. W. C. Etheridge, assistant in farm crops at Cornell University, has been appointed professor of agronomy. M. N. Beeler has been appointed to have charge of extension publications beginning July 1, as well as of the correspondence courses and a short course to be offered in agricultural journalism.

Georgia College.—J. P. Campbell has been appointed director of extension work.

Kentucky University and Station.—J. N. Camden, of Versailles, has succeeded L. L. Walker as a member of the board of control. A department of animal pathology and diseases of live stock was established July 1 with Dr. Robert Graham as head. Dr. Philip Lee Blumenthal, whose resignation from the Iowa Station has been previously noted, has been appointed research chemist, and H. K. Wright to a position in connection with the hog cholera serum laboratory.

Missouri University and Station.—J. O. Rankin, assistant agricultural editor at the Wisconsin University and Station, has been appointed agricultural editor beginning September 1. Among his duties will be the organizing and editing of the publication work of the college of agriculture and station, the supplying of agricultural items directly to the farm press, and the furnishing of news items regarding the college of agriculture to the university publisher. Other appointments include J. S. Gardner as assistant in horticulture beginning September 1, and D. J. Griswold as research assistant in animal husbandry beginning July 1.

Ohio State University and Station.—It is announced that of the 190 1915 graduates in the four-year course, 75 per cent were expecting to engage immediately in farming. Of the remainder, 10 per cent were to take up agricultural teaching and 5 per cent graduate work.

Plans for the new home economics building call for a three-story E-shaped structure, with 182-foot frontage and 136-foot wings. The first story will be of Bedford limestone and the remainder of brick. The main portion will contain offices, class rooms, a museum, etc., while the wings will be occupied by

laboratories, lecture rooms, a model apartment, dining rooms, an auditorium seating 500, etc.

The board of control for the station provided by the last legislature was named by the governor July 8 as follows: G. E. Jobe, Cedarville; Horatio Markley, Mt. Gilead; M. L. Ruetenik, South Brooklyn; Charles Flumerfelt, Old Fort; and George E. Scott, Mt. Pleasant. An act was also passed, authorizing the board of control to purchase lands suitable for the growth of forest trees at a price not exceeding ten dollars per acre and to manage such lands as state forests. An appropriation of \$10,000 was made for beginning this work. Other appropriations to the station included \$180,780 for salaries and labor and \$91,763.20 for maintenance. The fiscal year of the State has been changed from February 16 to July 1.

Oregon College and Station.—Requirements for admission to all degree courses at the college have been advanced from 12 to 15 units of high school credits, beginning with the next academic year. Provision for the admission of other students deemed sufficiently mature to select their life work and prepared to take advantage of the opportunities for college instruction is made through the vocational courses. The school of commerce announces additional courses in the literature and exposition of farm life, economics of distribution, and markets and marketing.

The following research assistants severed their connection with the station July 1: F. R. Brown, horticultural by-products; A. F. Vass, bacteriology; and Leroy Childs and G. F. Moznette, entomology. H. S. Jackson, head of the department of botany and plant pathology, has been appointed head of the botanical department of the Purdue Station to take effect September 1, vice Dr. J. C. Arthur who retires as a beneficiary under the Carnegie Foundation for the Advancement of Teaching.

Texas College and Station.—J. H. Foster, professor of forestry at the New Hampshire College, has been appointed state forester, professor of forestry, and forester to the station beginning September 1.

Virginia College.—T. J. Murray has been appointed associate professor of bacteriology and plant pathology.

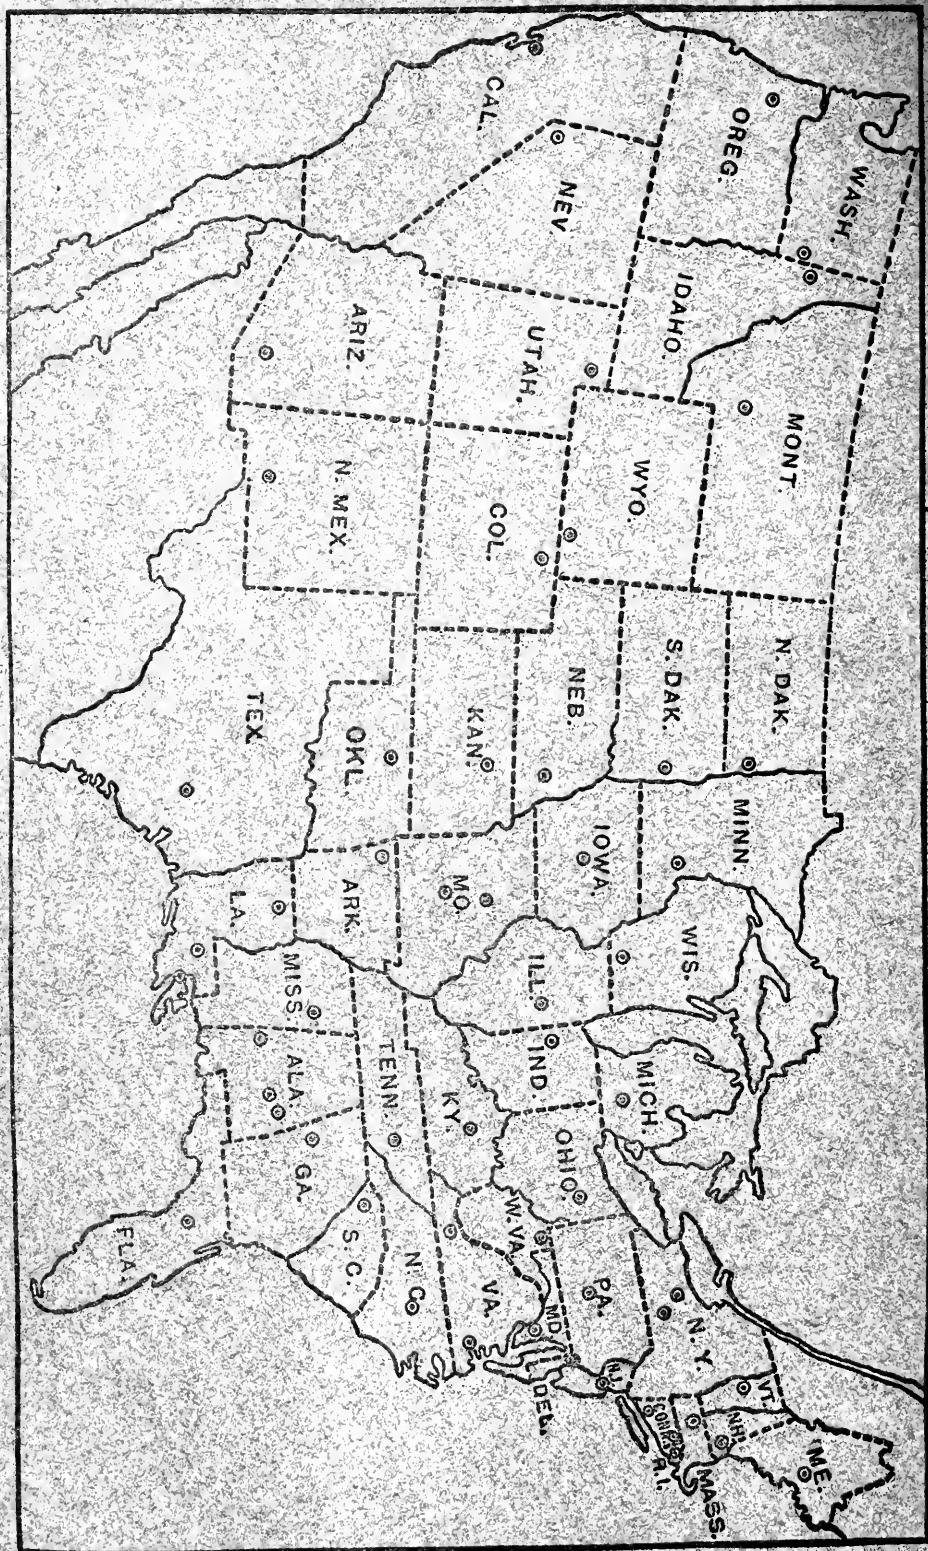

West Virginia University and Station.—Dr. John L. Coulter, of the George Peabody College for Teachers at Nashville, Tenn., has been appointed dean of the college of agriculture and director of the station, beginning September 1. Other appointments, effective August 1, include Jonathan Yoke as instructor in animal husbandry, vice R. R. Snapp, resigned; Arthur C. Ragsdale, instructor in dairy husbandry, vice George L. Thompson, resigned; and Aubrey J. Swift as instructor in animal husbandry in the college and assistant in animal husbandry in the station.

Association of Official Agricultural Chemists.—The thirty-second annual convention of this association is to be held at Washington, D. C., November 15-17. The arrangement of the program has been altered from that of recent years, the first day being given over to the reports of the referees on water, feeds and feeding stuffs, sugar, separation of nitrogenous substances, dairy products, and food adulteration. The second day is to be devoted largely to committee reports and the address of the president, and the third day to reports from the remaining committees and referees, including the sections of fertilizers and medicinal plants and drugs.

EXPERIMENT STATION RECORD.

VOL. XXXIII.

OCTOBER, 1915.

No. 5.

The question of experiment station publications continues to command attention. It formed one of the main topics on the program of the experiment station section of the Association of American Agricultural Colleges and Experiment Stations at its recent Berkeley meeting. An entire afternoon session was devoted to the discussion of the most effective forms in which to publish station work, and this was well warranted in view of its timeliness, its complexity, and its importance.

Consideration was given in the discussion to the annual report, the station bulletins, and the publication of scientific and technical material in the *Journal of Agricultural Research*, other scientific journals, and similar mediums. Some differences of opinion were expressed upon each class, and it is clear that the matter has not yet been fully worked out. This is not surprising, for despite an experience extending over twenty-five years conditions have been rapidly changing, especially of late, and in many instances policies have necessarily been influenced by local requirements and as a result of extension activities.

As regards the annual report, the general sentiment expressed was adverse to the practice of making it too detailed and voluminous. The inclusion of special articles and technical papers, or the binding of all the bulletins of the year together with an introduction into the report, was not looked upon as best meeting the needs of the situation economically or otherwise. In its place a reasonably brief annual report was favored, which would review the principal events of the year, discuss the work by projects, give a brief synopsis of the various publications issued, and report upon the station's resources and expenditures.

The character which the bulletins should now assume, and the best means of recording the more strictly technical features of station investigations, were considered at length but without definite conclusions. The procedure in this respect is a matter of special importance at the present juncture. With the assumption of the general information bulletins by the extension service, the most effectual

means of presenting station work needs to be carefully considered. Some stations have already modified their plan of publication; others have not.

The stations need to continue to maintain their own series of publications for presenting the results of their work to the agricultural public in a form which will be readable and easily understood. This definite end will naturally influence the character of the station bulletins. There is otherwise some danger that the station publications may become too exclusively technical. In that case their work would not reach the people directly as it has in the past, but would be filtered down to them through the extension service. The stations might thus lose to some extent in closeness of contact with the public and possibly in credit for their work. This would be unfortunate, since their prestige and their recognition as the source of reliable tested information must, of course, be maintained.

In addition to the dissemination of the practical results of station work among the agricultural public, the station publications have another important function. This is to record the more technical scientific results of their investigations for the benefit of other investigators and for the general advancement of agricultural science. It is naturally desirable that accounts of this work be placed where they will reach the special audience interested in them, and will be as permanent and accessible as reports of investigation in any other branch of science. They represent contributions to science and they deserve a place alongside similar contributions from other institutions. This is due the station as a scientific institution and the author as a scientific investigator. The ultimate purpose or application of the work need not alter the case.

It has come to be quite generally recognized that the regular bulletin series is not the best place for recording such features of station work in detail. To an increasing extent this material is being placed in the current scientific journals, and in a considerable number of cases a separate series of research or technical bulletins has been provided to which special distribution is given. The latter plan has numerous advantages. It avoids the commingling of the technical and the more popular material in the same series, and makes it possible to distribute each class appropriately. The main question appears to turn on its effectiveness and permanence as a means of publicity. Where the station output of technical material is confined to one or two bulletins a year, and these published at irregular intervals, they become more or less isolated and are correspondingly more liable to be overlooked by the scientific world.

Within the past year, a new medium of publication has been opened to the stations in the *Journal of Agricultural Research*. This

journal is now the joint official organ of this Department and the Association, with an editorial board drawn equally from each, and with department and station papers received and published on equal terms. Reference to it was made by Dr. Pearl, of the editorial board, in a paper at the Association meeting.

Articles have already been published or accepted for publication in the *Journal* from eighteen stations, indicating that it is meeting a real need in their work and is to receive their support in increasing measure. This is distinctly encouraging, for as Dr. Pearl stated, "in the editing of the *Journal* the attempt is being made to set a standard as to scientific content and literary form for the papers which shall be as high as the highest maintained by independent scientific journals, whether in the field of pure or applied sciences. . . . For the first time it provides a medium of publication altogether worthy of the best American work in agricultural science."

Beginning with Volume 5, issued in October, the *Journal* becomes a weekly in order to accommodate the increased material presented for publication. This will often have the effect of insuring greater promptness in publication.

The practice of outside publication is one which has been followed to a greater or less extent ever since the stations were started. Most of the earlier stations, it will be recalled, printed their bulletins in newspapers or the agricultural press, giving them regular serial numbers. In this way a large number of people were reached promptly and at small expense, but at an inevitable sacrifice as regards the permanence of the bulletins themselves. Periodicals of this sort are not usually preserved, and to-day it is practically impossible to assemble a file of these earlier bulletins. It is only by good fortune and a rare foresight on the part of the stations that a fairly complete collection was brought together by the Office of Experiment Stations, and this could not be duplicated if destroyed.

Since the passage of the Hatch Act, with its definite provision for the publication of bulletins and reports and their free transmission under frank, the bulk of the experimental work has been published by the stations themselves. Within recent years, however, there has been an increasing tendency to look to the various scientific journals and similar agencies for the reporting of some of the scientific and technical material. For this there are several reasons. The stations are employing larger staffs and attacking a greater number and variety of research problems, and in consequence are accumulating more results for dissemination than ever before. More of their studies are necessarily of technical scientific character. To a greater extent the stations are rapidly becoming research institutions, which

means that the results of their activities have an interest and value quite outside the agricultural public.

In many cases, however, the funds available for printing have not kept pace with the increase in the amount to be printed. Another important factor is the virtual doubling of the station mailing lists within the last decade in response to the growing popular desire for information, this appreciably increasing the size and cost of editions and adding to the demands upon the printing funds. Such conditions, unless remedied, would inevitably lead to a congestion of unpublished data, sometimes sufficiently great to jeopardize its timeliness and detract from its ultimate practical value. As a matter of fact, several of the stations are already facing this situation.

The scientific journals have performed a useful service in relieving a part of this congestion. The publication of the results of agricultural research in journals devoted to such general sciences as chemistry, botany, biology, and the like has also done much to secure recognition for it. There has been a greater certainty of bringing the research to the attention of workers in foreign countries and to others especially interested, with less likelihood of unintelligent criticism. In many cases there has been the special advantage of relieving the station bulletins of a considerable amount of detailed data of slight general interest, such as the minutiae of technical methods, complex mathematical formulas, and other material of a strictly technical nature.

Another frequent benefit was set forth by Dr. Pearl, which applies to the stations and to the station men themselves. In publishing in this way, "the work will be judged by the editorial board of the journal strictly on its own merits as a piece of scientific research, and on no other basis. *Journal* publication provides each director with an opportunity to see the scientific work of his station as others see it. Scientific papers are not unlike favorite sons—it is often very difficult for the fond parent to discern in them any faults at all. Independent editorial boards, on the other hand, do that sort of thing very well. If an independent chemical, or botanical, or zoological, or bacteriological, or agricultural journal refuses to publish a paper submitted from a station, the author and the director are bound to come to the conclusion, since no other is possible, that in some way or other this paper does not measure up to a standard which disinterested experts in the given field of knowledge regard as the irreducible minimum below which sound scientific work can not fall. On the other hand, if it is accepted the work receives the hall-mark of standard character." It is admitted, of course, that the limitations of space or of the field of a journal may lead to the rejection of papers, and it is true, moreover, that certain phases of station investigation

find among existing scientific journals no special medium to which they are directly appropriate.

These are real and concrete benefits, and it seems quite likely that, as Dr. Pearl predicted, "as the experiment stations take on more and more the character of research institutions, and leave behind more and more that type of activity which was essential at the beginning but is now being taken over by extension departments, there will be all the time an increasing proportion of the scientific output published in the standard established scientific journals."

At the same time there are some complications which arise in publishing station work outside the station. One of the most important of these is that of scattering the station work and rendering a portion of it less readily identified as a part of the activities of the institution. The objection is sometimes raised that this may detract from the credit accruing to the station. There seems little cause for apprehension on this score, however, as the journals are a well recognized standard channel for bringing new results to the attention of the scientific public. Furthermore, the very fact of this dispersal of station work calls wider attention to it. The *Journal of Agricultural Research* would serve to bring this material more largely together, and thus more adequately indicate the volume and variety of current agricultural research.

Whatever channel may ultimately be decided upon for the publication of the scientific and technical accounts of station work, the need of a general policy in regard to outside publications and of a systematic and formal method of procedure will be evident. There has been some laxity in this regard in the past. At least two requirements seem necessary to be observed: Each paper should be plainly accredited to the station from which it emanates, and record of it should be preserved in the station files.

The principles in the matter seem quite clear. Since the kind of material under discussion is that derived primarily from station funds and work, it is for the station to determine its disposition, and to look upon it as a part of its published records. It should, therefore, realize its responsibility in these articles. It may be necessary for it to consider whether the utilization of an external medium will be in harmony with its general policy and preferable to the use of its own publications, whether the journal selected is the one best adapted for the purpose in view, whether the space available and style of treatment are adequate, and similar questions, bearing in mind both its own interests and those of agricultural science and of agriculture as a whole.

Of late these journal articles have come to contain a relatively large proportion of the technical results reported in some lines, and much

of it is available in no other form. The articles constitute an essential part of the station's permanent records, and hence merit due care and attention to see that they may be readily identified with and accredited to the institution. If, as has sometimes occurred, they have not been accredited to the institution, by footnote or otherwise, or if the station has not followed some system of keeping track of them so that they can be traced by those interested, the difficulty of obtaining a complete record of work performed is much increased. The fact that the stations are state institutions and are required to report upon their activities makes these matters more important than might be the case with other classes of institutions.

Furthermore, it is important that each station should preserve a file of all of its publications, whether issued by it directly or through a journal. But unfortunately the systematic collection of the separates of journal articles in the libraries or files of the respective stations has not been a matter of uniform practice, and it is feared that a considerable number of stations lack copies or even a record of these products of their own investigations. It seems desirable also that the annual report of the station should contain a list of these technical papers, and often a synopsis of them. This places them definitely on record and makes it easier to find the references to them.

Several stations are already publishing such lists, while some are giving greater prominence to this literature. Thus in New Hampshire, reprints of the articles are obtained and reissued by the station in a numbered series entitled *Scientific Contributions*. The North Carolina Station has reprinted in its annual report some articles originally appearing in scientific journals. Recently the Maine Station included in its annual report not only the titles of the papers but a brief abstract in each case. Such practice meets to a considerable extent the feeling shared by some of the stations that all their work should be published in some form in their own series.

In what is said as to procedure, it is of course not intended to minimize the position of the author of such scientific papers or to eliminate him from consideration. He deserves the credit and the stimulus which come from publication of his work. As in the conduct of the work itself, a large measure of freedom is to be expected. But because of its position as a public institution the station needs to be a party in the matter of publication as it is in the general oversight of the investigations, and the credit to the author loses nothing by association of its name with it.

The station and the investigator are in partnership in carrying on certain lines of investigation. Both are interested in giving the product of this partnership to the world in a way which will be most effective and bring greatest usefulness. It goes out as a contribution

from the station, whether in bulletin or journal form, but the investigator is credited with being the real author of the work and is so recognized by the reading public. In that sense it is his work. In a large degree the investigators comprise the station, and the organization exists to give them support and opportunity and in numerous ways to represent them before the public.

These principles are quite generally recognized in the Federal Department of Agriculture where outside publication has greatly increased in recent years, both as a means of relief from congestion of material and as a more effectual means of recording certain types of scientific work. While considerable latitude is followed in the matter, permission for outside publication is required and proper credit to the Department insured. Copies of such manuscripts are retained in the Department and a permanent record is kept of all publications of this nature as they appear.

Such Department papers, like those of the stations, are widely disseminated in the literature and easily lost sight of. To avoid the latter difficulty, an effort is now being made, beginning with the present volume of the *Record*, to include references to all Department papers reporting scientific or technical work. The range of the Department's work, including as it does extensive police and supervisory functions, is somewhat broader than that of the *Record*, and papers which do not relate rather definitely to agricultural subjects will be listed by title only. The lists will be combined in the index number of the *Record*, and it is hoped that they may prove of service, both as a convenient means of reference and, by assembling the material in a comprehensive way, to convey more adequately a conception of the full scope and importance of the researches of the Department.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

The hexone bases of casein, D. D. VAN SLYKE (*Jour. Biol. Chem.*, 16 (1914), No. 4, pp. 531-538).—In a preliminary description (*E. S. R.*, 25, p. 710) of the method for the analysis of proteins by the determination of the chemical groups characteristic of the different amino acids, an analysis of casein was reported. The results agreed well with the analysis reported by other investigators in work with the Kossel method. "The discrepancy, noted in the preceding article, between the free amino nitrogen of casein, and the lysin content previously determined, rendered a repetition of the nitrogen distribution in this protein desirable." The bases were determined by the method of Kossel and Patten as modified by Osborne, Leavenworth, and Brautlecht (*E. S. R.*, 20, p. 1102), and the bases and nitrogen distribution were redetermined by the modified Van Slyke method.

The most significant difference between the present results and the previous ones occurred in the lysins. By exercising particular care in the Kossel method, 9.36 per cent of the casein nitrogen was obtained as the analytically pure picrate. The group determination gave 10.3 per cent which is believed to be more nearly correct, as the amount of lysin picrate which one can crystallize represents necessarily the minimum amount present.

"For arginin the results are practically the same, 7.4 to 7.8 per cent of the total nitrogen, as those previously obtained by both methods. The histidin results are a little higher than previously, but not to a marked extent.

"The source of error in the author's former results for lysin lay in the cystin determination. The lysin is estimated from the total amino nitrogen of the bases precipitated by phosphotungstic acid, after the cystin nitrogen has been subtracted. The cystin was estimated from the amount of organic sulphur precipitated with the bases. The original form of the method, however, made the cystin figures liable to error from the fact that sulphates could be dissolved from a glass flask used in one stage of the operation."

In the form in which the method was modified (*E. S. R.*, 26, p. 22), the sources of error in the cystin and lysin determinations have been eliminated. "In the determination by the picrate method, as usually performed, it appears that the most probable source of loss lies in the decomposition of lysin phosphotungstate with barium hydrate. In this operation one insoluble precipitate (lysin phosphotungstate) is transformed into another (barium phosphotungstate) a process the completeness of which is necessarily difficult to judge. Moreover, the bulky barium phosphotungstate has marked adsorptive properties, so that even skill and experience might not insure against loss from this source. In working out the details of the group determination method, it was noticed that several per cent of the total nitrogen of the protein could be lost from the base fraction through adsorption or occlusion by the barium precipitate." A practice is made of reducing this loss to a minimum by completely dissolving the bases precipitated by phosphotungstate acid with alkali and precipitating the barium phosphotungstate in a dilute solution. The best results

with the Kossel method were obtained when the lysin phosphotungstate was dissolved in ammonia and the solution diluted to a large volume before treating with barium hydrate.

Oxyproteic acids, P. GLAGOLEW (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 89 (1914), No. 6, pp. 432-440; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 621, I, p. 885).—These substances, having the nature of polypeptids, possess a definite number of amino groups which increases on hydrolysis. The amino acid nitrogen when estimated by Van Slyke's method (*E. S. R.*, 26, p. 22) amounts to 44.3 per cent of the total nitrogen. Most of the nitrogenous substances, viz, 80 per cent, obtained on hydrolysis of oxy- or alloxypoteic acid were not precipitated by phosphotungstic acid. Both of the acids contained cystin and arginin. Hydrolyzing with 25 per cent of hydrofluoric acid (*E. S. R.*, 22, p. 301) prevents the formation of melanins, and ammonia production is less than when 20 per cent of boiling hydrochloric acid is employed.

Oils of the Coniferæ.—III, The leaf and twig and the cone oils of western yellow pine and sugar pine, A. W. SCHORGER (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 11, pp. 893-895).—In western yellow pine the percentage composition of the leaf and twig and the cone oils, respectively, is approximately as follows: Furfurol ? per cent and trace; *l*-pinene 2 and 6 per cent; *l*-pinene 75 and 60 per cent; dipentene 6 and 12.5 per cent; ester as bornyl acetate 2 and 2.5 per cent; free alcohol (*l*-borneol) 7 and 4 per cent; "green oil" 3 and 3.5 per cent; and undetermined material 5 and 10 per cent. In sugar pine the leaf and twig and the cone oils contain, respectively, furfurol in trace; *l*-pinene 21 and 22 per cent; *l*-camphene ? and 21 per cent; *l*-pinene 51 and 39.5 per cent; dipentene 12 and 4.5 per cent; ester as bornyl acetate 1.5 and 1.5 per cent; free alcohol (*l*-borneol) 8 and 3.5 per cent; "green oil" 1 and ? per cent; sesquitorpene (?) ? and 1 per cent; and undetermined material 7 and 7 per cent.

Oils of the Coniferæ.—IV, The leaf and twig oils of digger pine, lodgepole pine, and red fir, A. W. SCHORGER (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 1, pp. 24-26).—The constituents found in the leaf and twig oils of digger pine, lodgepole pine, and red fir, are, approximately, as follows: Furfurol, 0 per cent, trace, and trace, respectively; π -heptane, 3, 0 per cent, and 0 per cent; α -pinene, 58 to 59 per cent, 3, and ? per cent; α -camphene, 0 per cent, 5 to 6 per cent, and 0 per cent; β -pinene, 0 per cent, 49 to 50 per cent, 16 to 18 per cent; α -limonene, 18.0 per cent, and 0 per cent; bornyl ester (as acetate) 3.5, 2, and 3.5 per cent; free alcohol (as *l*-borneol), 6, 7.5, and 7.5 per cent; methylchavicol, ? per cent, ? per cent, and 0 per cent; "green oil," 2 to 3 per cent, 0 per cent, 13 per cent; cadinene, 0 per cent, 7, and 0 per cent; and losses by polymerization, etc., 9.5, 6, and 6 per cent. The dipentene and α -phellandrene were determined together in lodgepole pine and amounted to 19 per cent; the dipentene and α -phellandrene content of red fir and digger pine leaf and twig oils were 0 and 52 per cent, respectively.

Contribution to our knowledge of the oxidation ferments of plants, O. BEGEMANN (*Ztschr. Allg. Physiol.*, 16 (1914), No. 3-4, pp. 352-358).—This investigation deals with oxidase, peroxidase, catalase, and reductase.

Existing qualitative and quantitative methods for determining the activity of oxidase were studied, but aside from Chodat and Bach's method for peroxidase, in which the purpurogallin is weighed, no method, according to the author's knowledge, is available for the purpose. Two new colorimetric methods in which the benzidin reaction is the basis are presented.

Reductase was studied qualitatively and quantitatively with methylene blue.

The questions especially studied were the distribution and the quantitative location of the ferments in plants. Oxidizing ferments were found widely distributed, but the quantities present differed markedly. Numerous sections of

roots, stems, cotyledons, plumules of *Pelargonium* seedlings, sections of *Lemna minor*, *Riccia fluitans*, *Nectria cinnabarina*, *Scolopendra vulgaris*, and *Ricinus communis* were studied. Some Mucorineæ with sporangia were examined for catalase, but the hyphæ were found to contain catalase only on the exterior. Sections through geranium seedlings showed that catalase was especially active in the region of the vascular system. Even in the wide lumened *Scolopendra* leaf and in the large vessels of the *R. communis* leaf the gas originated outside of the living cells. Bubbles could be observed on the walls of the cells but not within. Staining tests with eosin showed that where this coloring matter penetrated hydrogen peroxid could also gain entrance and this was proved by the catalase reaction which occurred.

Eosin and hydrogen peroxid, however, did not penetrate the living cell. Tests on *L. minor* and *R. fluitans* proved that green chlorophyll is not catalytic. By treating the objects with infusorial earth the chromatophores were isolated. In all localities where catalase was found peroxidase could also be noted. Peroxidase was found by Chodat and Bach's pyrogallol method in the vascular and in the intercellular tissues, but not in the chromatophores, and, like catalase, not on the epidermis and its formations, i. e., buds, hairs, etc. If a preparation of pyrogallol and glucose was added, the pyrogallol passed through the tissue and the reddish brown purpurogallin crystals could be seen in the interior of the cell, indicating direct oxidase. An increase of temperature increased the catalase and peroxidase content of seedlings. The various lengths of light rays acted specifically upon catalase and peroxidase formation and gradually increased both in amount. Potato buds and geranium seedlings were studied in this respect. Catalase and peroxidase activities are two artificial phenomena, and it is concluded that they represent two concurring reactions whose courses are dependent upon conditions favorable to one or the other.

Assuming that oxygenase is an aldehyde-like substance, it may also produce reductions, i. e., act as a reductase. Methylene blue, according to this, when a peroxidase is absent will be reduced outside of the cell. Therefore, oxygenase might be identical with reductase or with the catalase and peroxidase reactions, two artificially produced reactions in which oxygenase is the basis. Extracts from potato buds were used to prove a portion of this theory and the influence of temperature, light, and dialysis were noted. A marked parallelism for catalase, oxidase, and peroxidase was found at 50, 60, 70, 78, 79, and 80° C. Both reactions decreased slowly in activity at 78°, were only slightly present at 79°, and ceased at 80. This is believed to prove the identity of the enzymes. Geranium seedlings grown in nutrient solutions were exposed to red, blue, violet, green, covered, and uncovered incandescent lights. Almost all of the tests gave a complete parallelism between the catalase and peroxidase reaction, the length of the ray controlling the amount of ferment present. Dialysis tests with potato bud extracts showed that catalase and peroxidase passed through the semipermeable membrane with the same degree of rapidity. Direct oxidase behaved in the same manner as catalase and peroxidase. The position of reductase in the system was as follows: Catalase—oxidase—peroxidase—and reductase.

The enzymes of *Aspergillus terricola*, F. M. SCALES (*Jour. Biol. Chem.*, 19 (1914), No. 4, pp. 459-472).—“*Aspergillus terricola* produced inulase, diastase, invertase, maltase, alcoholoxidase, emulsin, lipase, protease, and amidase when grown in a medium without these substances. It is evident from the number of enzymes formed that filamentous fungi as well as bacteria may be concerned in the production of the various organic decomposition products which have been isolated from the soil.

“Many of the products of enzymic action are excellent sources of carbon and nitrogen for bacteria. The ammonia produced by the fungus from protein material may, in the form of a salt, be directly assimilated by some plants. The living organism hydrolyzes a small amount of cellulose in cellulose agar, but the presence of cellulase could not be demonstrated in an enzym powder. Neither lactase nor zymase were present in a powder from the growth in lactose and glucose solutions respectively. Tannase was produced by the fungus when grown in a tannin solution. The fungus showed no nitrogen-fixing power in nutrient solutions containing either a carbohydrate (dextrose or mannite) or nitrogenous substance (peptone or ammonium sulphate) or both together.”

The soluble polysaccharids of lower fungi.—I, **Mycodextran**, a new polysaccharid in *Penicillium expansum*, A. W. DOX and R. E. NEIDIG (*Jour. Biol. Chem.*, 18 (1914), No. 2, pp. 167-175).—“This paper presents a study of a soluble polysaccharid isolated from the apple fungus, *P. expansum*, which has heretofore not been recognized in fungi nor observed in any of the higher plants.” The organism was selected for study on account of its great importance to the apple industry. The indications were that the fungus also contains mannitol, peptone, glucose, inorganic salts, amino acids, pentosans, hemicelluloses, and a chitin-like substance which on hydrolysis yields glucosamin.

The soluble polysaccharids of lower fungi.—II, **Mycogalactan**, a new polysaccharid in *Aspergillus niger*, A. W. DOX and R. E. NEIDIG (*Jour. Biol. Chem.*, 19 (1914), No. 2, pp. 235-237).—A polysaccharid was obtained from a not quite mature culture of *A. niger*. It was found to be a galactan and the name mycogalactan is proposed. Mycogalactan like mycodextran (see above) appears to be a reserve carbohydrate and is used by the fungus as a food supply as soon as the sucrose of the medium is exhausted.

Selective adsorption, E. G. PARKER (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 10, pp. 831-835, figs. 2).—“Soils not only have the power of absorbing dissolved salts from solution, but also adsorbing one ion at a greater rate than the other, or of selectively adsorbing to an extent easily determined quantitatively. The nature of the surface of the constituents of a soil is such that the cation is adsorbed at a much greater rate than the anion.

“The presence of bases of the soil (Ca, Mg, etc.) in solution, after contact of certain salt solutions with a soil, is not due to a direct chemical reaction of the salt in solution with the silicates of the soil, but to a secondary reaction of free acid resulting from the selective adsorption of the cation with the mineral constituents of the soil. In general, the smaller the soil particles the greater the selective adsorption of the cation. The selective adsorption of the cation from a solution of an electrolyte by a soil increases with the concentration up to a certain point, and then remains practically constant, the surface of the soil particles having taken up all that it is able at this point. At very low concentrations the adsorption of the cation is practically complete. The presence of other substances may or may not affect the selective adsorption by a soil.”

The determination of ammonia in soils, R. S. POTTER and R. S. SNYDER (*Iowa Sta. Research Bul.* 17 (1914), pp. 3-19, fig. 1).—These experiments were conducted with a view of supplying a reliable method for the estimation of the ammonia in soils. It is claimed that the method should meet the following requirements: “Closely agreeing duplicate results should be given and the same result obtained whether the reagent or reagents act, within reasonable limits, for a longer or shorter period. . . . Upon the addition of a known amount of ammonia, the method must give this added amount plus that previously found in the soil. . . . For use in a soils laboratory, the method should

permit one to run several determinations within a reasonable length of time. . . .

"It was found, from a comparison of methods, that the amount of ammonia extracted by hydrochloric acid from soils is within the limits of our experiments, independent of the strength of the acid and the period of extraction. In the five soils tested hydrochloric acid removes approximately from 60 to 70 per cent of the ammonia added. The Folin aeration method can advantageously be applied directly to the hydrochloric acid extract. The amounts of ammonia obtained by distillation of the soil directly with magnesia is dependent upon the duration of the distillation. The Steel method of aeration [E. S. R., 24, p. 703] is not suitable for the determination of ammonia in soils. The Steel reagents slowly decompose acetamid.

"The Folin method of aeration is suitable for the determination of ammonia in soils, for the same result is obtained whether the reagent acts for a shorter or longer period, and all added ammonia is recovered." "The digestion is carried out in the usual way, and the aeration conducted in much the same way as Kober recommends. . . .

"In the soils tested there is no interference through formation of triple phosphate. There was no advantage found in using sodium chlorid with the sodium carbonate. Acetamid is not decomposed by 4 per cent sodium carbonate. The results for ammonia obtained by examination of the hydrochloric acid extract are lower, while the results obtained by direct distillation of the soil with magnesia are higher, than those obtained by the aeration method. The high results obtained by the former method are due to occlusion of the ammonia by the soil, the nature of which is not clear, and the lower results by the latter method are due to a partial decomposition of the organic material by the magnesia to give ammonia."

See also previous notes by Kelley and McGeorge (E. S. R., 30, pp. 419, 420).

Solubility of calcium phosphates in ammonium citrate solution, T. WARYNSKI and J. LANGEL (*Ann. Chim. Analyt.*, 19 (1914), No. 1, pp. 1-6; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 617, II, p. 216).—In view of the fact that mono-, di-, and tri-basic calcium phosphates are soluble in both water and ammonium citrate solution to some extent, the method in use for separating these salts, which depends on the insolubility of di-basic and tri-basic calcium phosphates in water, yields only approximate results. The solubility of the salts in ammonium citrate solution reaches an equilibrium in about one hour at 30° C., but this is not strictly the case with fertilizers where the phosphates may be enveloped by other substances. A better separation may be obtained by treating the phosphates for one hour with a cold saturated ammonium citrate solution. The solubility of the mono- and tri-basic phosphates varies with the concentration of the citrate solution and reaches a maximum with a concentration of from 10 to 15 per cent.

Separation of calcium from magnesium, F. HALLA (*Chem. Ztg.*, 38 (1914), No. 10, p. 100; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 617, II, p. 219).—The following method is recommended for the separation of very small quantities of calcium in the presence of large amounts of magnesium:

"The neutral solution containing the chlorids of the two metals is heated to boiling, and solid ammonium oxalate is added until the magnesium oxalate, at first precipitated, redissolves; the calcium oxalate remains insoluble. After a few hours, the calcium oxalate is collected on a filter, washed with hot water, then with cold water, ignited, sulphated, and weighed as calcium sulphate. The magnesium oxalate may be precipitated from the filtrate by the addition of acetic acid."

Titration of small quantities of carbon dioxide, A. DORNER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 88 (1913), No. 6, pp. 425-429, fig. 1; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 617, II, p. 218).—In this method, heating of the barium hydroxid is dispensed with because it leads in glass vessels to an appreciable change of titer. In the modified process good results are obtained by absorbing the carbon dioxide with $\frac{N}{100}$ barium hydroxid in the cold using a special form of apparatus which is shown.

A comparison of methods for the determination of oxygen in waters in presence of nitrite, E. ELVOVE (*Pub. Health Serv. U. S., Hyg. Lab. Bul. 96* (1914), pp. 15-35).—"In comparison with the Winkler method, the Levy method^a is decidedly disadvantageous. Regarding the Winkler method as modified by Hale and Melia (E. S. R., 31, p. 411), it is pointed out that their warning 'that solutions acidified ready for titration should not stand in contact with air for several hours before titrating' may be misleading, since low results were obtained even when the solutions were kept in closed bottles which had been completely filled with these solutions. Furthermore, even a period of only one hour was sufficient to cause low results. In the presence of considerable nitrite the results may also be too high if there is not a sufficiently long period intervening between the addition of the potassium acetate and the titration of the iodine.

"In order to obtain accurate results by the acetate modification of the Winkler method, the titration should therefore be carried out immediately after a certain interval has elapsed since the mixing with the potassium acetate. Under the present conditions (5 parts per million of nitrite and temperature about 20°C.), an interval of 15 minutes was found to be the proper time to allow for the potassium acetate to remain in contact with the iodine before the latter is titrated.

"Hale and Melia's apparent explanation of the counteracting effect of the acetate on the nitrite interference on the assumption that its function is 'to neutralize the hydrochloric acid and render the solution acid with acetic acid' does not seem to be a sufficiently complete explanation, since an acetic acid medium was found not to prevent these interferences. The power of potassium acetate to counteract the nitrite interference is probably due to its further depression of the dissociation of the acid; an excess of the acetate is therefore essential.

"The permanganate modification of the Winkler method, since it is applicable in the presence of nitrite and organic matter, is preferable to the acetate modification which counteracts only the interference from nitrite. In carrying out the permanganate modification in bottles of about 270 cc. capacity, each bottle should contain not less than 0.45 gm. potassium iodide and the amount of excess of potassium oxalate should not be more than 1 cc. of the 1 per cent solution."

A study of the methods for extractions by means of immiscible solvents from the point of view of the distribution coefficients, I, J. W. MARDEN (*Jour. Indus. and Engin. Chem.*, 6 (1914), No. 4, pp. 315-320).—"A practical application of the distribution ratio has been made in a study of a few of the extraction methods given in the bulletins of the U. S. Bureau of Chemistry with the view of pointing out the fact that definite directions are needed in our extraction methods which give a definite amount of the material in question. A modification of the method of analysis for acetanilid in hydrogen peroxid has been suggested. The method for acetanilid, vanillin, and coumarin

^a Arch. Hyg., 32 (1897), p. 305.

in vanilla extracts has been discussed from the point of view of the distribution ratio. The methods now in use for salicylic acid, benzoic acid, and β -naphthol have been studied and found satisfactory from this point of view. A method has been suggested for the analysis of saccharin by extracting with amyl acetate and a modification of the present method with sulphuric ether proposed which gives definite results. It has been shown in the analysis of caffeine (in the particular case referred to) that the amount of chloroform used for the extraction was excessive. The fact has been emphasized that a larger number of extractions, using a smaller volume of solvent for each washing, is better than a fewer number of extractions using a larger amount. A much more extended study of the methods of extraction is being carried on in this laboratory at the present time."

A reaction of succinic and malic acids, W. OE. DE CONINCK (*Bul. Soc. Chim. France*, 4. ser., 15 (1914), No. 2, pp. 93, 94; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 617, 11, p. 224).—When a concentrated aqueous solution of succinic acid is added to a suspension of several grams of calcium salicylate in a little cold water and the mixture gently warmed, a pale pink coloration is quickly obtained which persists for several days even when the mixture is exposed to direct sunlight. Under similar circumstances malic acid develops a delicate pink coloration which gradually disappears when the mixture is gently boiled. It is completely removed after several hours and the liquid then becomes yellowish brown in color.

Methods for the detection and investigation of tryptoproteases, F. M. MARAS (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 74 (1914), No. 5-6, pp. 505-515).—The methods studied were the fibrin method, Mett's method, Fermi's gelatin plate method, the serum plate method according to Jochmann and Müller, the Gross and Fuld casein method, and the biuret, tryptophan, and tyrosin reactions. Fermi's method gave more satisfactory results than those of either Jochmann and Müller or Gross and Fuld.

The distillation of volatile fatty acids and the value of the Reichert-Meissl number, J. PRESCHER (*Chem. Ztg.*, 38 (1914), Nos. 112-113, pp. 1081-1083; 114-115, pp. 1091-1093).—A digest of the literature.

Catalase and reductase determination in cow's milk in practice and the relation between catalase and reductase on the one hand and the specific gravity, fat, and acidity on the other, A. STETTER (*Milchw. Zentbl.*, 43 (1914), No. 14, pp. 369-381, figs. 2).—The morning and evening milk from two dairies was examined fairly regularly during the year 1913 for specific gravity, fat content, reductase, and acidity. The cows were fed chiefly hay and various concentrates, with beet tops and leaves during the fall months.

No relation was found to exist between the catalase and reductase figures and the specific gravity or fat content of milk. On the other hand, a high acidity degree almost always pointed to a high reductase content. No correlation was found between acidity and the catalase figures, as milk with a high acid value often showed a normal catalase figure. It often occurred that the catalase and reductase figures of the morning and evening milks were alike but, generally speaking, the figures for each were highest in the evening milk. The catalase figure varied considerably from day to day and the reductase test also showed very marked variations. In most instances a milk which decolorized (reductase test) in one-quarter hour also had a high acid value. Although a high catalase and reductase figure lead to a suspicion of pathological milk, still one must be cautious when pronouncing a condition pathological on the basis of these tests.

Description of the cryoscope, and several freezing-point determinations of a single sample of fresh milk with varying degrees of supercooling, M. C. DEKHUIZEN (*Chem. Weekbl.*, 11 (1914), No. 4, pp. 126-131, fig. 1; *abs. in Jour.*

Chem. Soc. [London], 106 (1914), No. 617, II, p. 169).—This is a modified form of Beckmann apparatus. "The cooling bath is large, and consists of two concentric glass cylinders, the inner one 17 by 27 cm., and the outer 23 by 30.5 cm. The copper cover is replaced by a thick plate of ebonite. The freezing tube is round at the closed end, and is surrounded by a two-walled Dewar vacuum tube. The part projecting above the ebonite cover is protected by a wooden air chamber to prevent change of temperature." Cooling is promoted by immersing in a wide test tube containing mercury cooled to a suitable temperature.

The results of a series of experiments on a sample of milk are given.

The influence of ammonium sulphate upon the specific rotation of lactose, R. ROSEMAN (Höppe-Seyler's *Ztschr. Physiol. Chem.*, 89 (1914), No. 1-2, pp. 133-140).—The results show that the specific rotation of lactose is reduced when ammonium sulphate is present and that the reduction increases with a corresponding increase of ammonium sulphate to the solution. In a solution saturated with ammonium sulphate the rotation is reduced from 52.53 to 50.47°, and in the Salkowski method (*E. S. R.*, 27, p. 506), which employs a solution with 40 per cent ammonium sulphate, from 52.53 to 51.55°. With a solution containing from 4 to 6 per cent of lactose the results will consequently appear from 0.07 to 0.11 per cent too low, which corresponds to the figures found by Jahnson-Blohm, i. e., 0.08 to 0.14. As Kretschmer found values which were generally higher with the Salkowski method it seems advisable to make no corrections at all.

On the estimation of fat in feces, F. C. GEPHART and F. A. CSONKA (*Jour. Biol. Chem.*, 19 (1914), No. 4, pp. 521-531, fig. 1).—The proposed method is said to be time saving and to yield good results with feces for fat or cholesterol ester determinations.

"Weigh out finely powdered or well mixed moist sample. Saponify with KOH in alcohol (4 gm. of stick KOH and 20 cc. of 95 per cent alcohol). Dilute with 50 cc. of water and acidify with HCl (20 cc. of 20 per cent in 5 cc. portions). Shake out with ether and wash ether extract. Distil off ether and dry fatty acids. Take up with petroleum ether, filter, and titrate with $\frac{N}{10}$ alcoholic KOH. Calculation:

$$\frac{\text{CC. } \frac{N}{10} \times 0.0296}{\text{Weight of substance taken}} \times 100 = \text{per cent tristearin.}$$

"By the Liebermann-Székely method one determines a small amount of cholesterol with the fatty acids. The Kumagawa-Suto method is laborious and difficult of manipulation, and does not yield good results with pure fats or cholesterol esters."

A volumetric method for the estimation of total sulphur in urine, G. W. RAIZISS and H. DUBIN (*Jour. Biol. Chem.*, 18 (1914), No. 2, pp. 297-303).—This volumetric method has for its basis the estimation of the precipitate of benzidin sulphate rather than of sulphuric acid. Benzidin in an acid medium reduces potassium permanganate quantitatively with the instant production of a canary-yellow product which on further oxidation is converted into a colorless substance. With the method very small amounts of sulphate may be accurately determined in a short time.

SOILS—FERTILIZERS.

Lake County soils, C. G. HOPKINS, J. G. MOSIER, E. VAN ALSTINE, and F. W. GARRETT (*Illinois Sta. Soil Rpt. 9 (1915), pp. 52, pl. 1, figs. 9*).—This is the ninth of the series of the Illinois county soil reports and deals briefly with the

physiography, topography, and formation of the soils and more fully with soil material and soil types, chemical composition of the soil, and field tests of the fertilizer requirements of some of the prevailing types.

Lake County lies in northeast Illinois in the late Wisconsin glaciation. The soils of the county are divided into four classes, as follows: (1) Upland prairie soils, usually rich in organic matter, (2) upland timber soils, including nearly all upland areas that were formerly covered with forests, (3) terrace soils, which include bench lands or second bottom lands that were formed at the time of the melting of the glacier, and (4) swamp and bottom land soils, which include the overflow lands or flood plains along the streams, the swamps around some of the lakes, the poorly-drained lowlands, and the area of sand beaches deposited by Lake Chicago.

The yellow-gray silt loam of the upland timber soils covers about 40 per cent of the county, the brown silt loam of the upland prairie soils about 28 per cent, and the swamp and bottom land soils about 15 per cent. It is emphasized that the supplies of some of the necessary elements of fertility in the plowed soil of the most prevalent types in the county are extremely limited when measured by the needs of large crop yields. The variation among the different types of soils in the county with reference to their plant food content is also very marked. "Thus, the yellow silt loam contains in 2,000,000 lbs. of surface soil sufficient total nitrogen for 12 'maximum' crops of corn, sufficient phosphorus for 31 crops, and potassium for 800 such crops; while the deep peat contains in 1,000,000 lbs. of surface soil, nitrogen for 217, phosphorus for 67, and potassium for only 53 corn crops of 100 bu. each." It is stated that more than 90 per cent of the soils of the county contain no limestone in the surface or subsurface to a depth of 20 in.

Improving Iowa's peat and alkali soils, W. H. STEVENSON and P. E. BROWN (*Iowa Sta. Bul. 157 (1915), pp. 43-79, figs. 15*).—This bulletin describes the peat and alkali soils of Iowa and reports field and laboratory studies to determine methods of reclamation and cropping which will render them profitably productive.

There are two classes of peat deposits in Iowa, namely, the shallow peat, varying from a few inches to 3 or 4 ft. in depth, and underlain with a clayey or muck subsoil; and the deep peat, ranging from 5 to 15 ft. in depth. The shallow peats tested contained an abundance of lime, nitrogen, and organic matter, but the potassium and phosphorus contents were low. "The muck or clay underlying the shallow peats are, however, rich in potassium and contain some phosphorus, so that the lack of these two elements in the peat does not restrict crop production to any large extent."

Field tests of the shallow peats showed that limestone, gypsum, phosphorus, and potassium applied alone or in combination in amounts in which such materials are usually applied to soils produced no profitable increase in crops. These results are taken to indicate that the shallow Iowa peats do not need the addition of commercial fertilizing materials to make them productive. Methods of treatment recommended are (1) adequate drainage, (2) proper plowing and cultivation, and (3) the choice of crops best suited to such soils. Fall plowing and deep plowing are considered to be advisable for peat soils and timothy and alsike clover are thought to be the best crops to grow on reclaimed peat soil.

The salt deposits on the surface of the alkali soils of Iowa consist mainly of calcium carbonate and sodium in the form of sulphate and bicarbonate and occasionally nitrate. Tile drainage is considered to be the quickest method of preventing the appearance of alkali in these soils and a liberal application of manure is the most effective means of removing the salts causing the alkali

deposit. The plowing under of straw and green crops is also said to be of much value.

The radio-active content of certain Minnesota soils, J. C. SANDERSON (*Amer. Jour. Sci.*, 4. ser., 39 (1915), No. 232, pp. 391-397, fig. 1).—Reference is made to previous work by the author (E. S. R., 25, p. 718) and others bearing on the subject, and experiments to determine the interdependence, if any, existing between the radio-active content and fertility of 13 Minnesota soils are reported. The apparatus and method of procedure used in determining the radium content of a soil are also described.

Without exception, the very fertile soils were found to be richer in radium and thorium emanations than soils of inferior fertility, which it is stated is in accord with the results of experiments on artificial enrichment of soils. "The conclusion seems justifiable that the hygroscopic properties of a soil are a valuable index of its fertility . . . because the presence of moisture increases the radio-active emanating power of the soil and . . . the ability to retain moisture implies fineness of texture, which also means great emanating power, so that at least part of the effect is due to a greater proportion of 'free' radium and thorium emanations."

A report on the Piedmont soils, particularly with reference to their nature, plant food requirements, and adaptability to different crops, C. B. WILLIAMS ET AL. (*Bul. N. C. Dept. Agr.*, 36 (1915), No. 2, pp. 122, figs. 14).—This report deals briefly with the origin, topography, and drainage of the soils of the Piedmont section of North Carolina and more fully with the soil material, soil types, chemical composition of the soils, and field tests of the fertilizer requirements of certain of the prevailing types.

This section, including about 38 per cent of the State or 11,814,700 acres of land, embraces a wide belt running in a northeast and southwest direction across the central part of the State. The topography is dominantly rolling and uneven. The soils are all of residual origin and with the exception of a few local areas have good natural surface drainage. It is stated that the soils of the region are adapted to a wide range of crops, including field, truck, and fruit crops.

"While there is considerable variation, all the Piedmont soils have been found to be fairly high in potash, low in phosphoric acid, and to contain a fair amount of lime. The amount of nitrogen is usually very small. . . . In most of the Piedmont soils there is sufficient potash in the surface soil to produce maximum crops for a hundred years or more, while twenty to twenty-five such crops would entirely exhaust the phosphoric acid. . . . As a general thing crops like corn, cotton, and wheat are not generally benefited by applications of potash, but phosphoric acid first and nitrogen second, except with the Iredell loam where it is first, are the controlling constituents in increasing yields. In the use of fertilizers for the production of profitable crops or for the improvement of the soil, liberal applications of phosphates must be made, and nitrogen must also be supplied either in fertilizers or from soil-improving crops. Lime has not materially increased the yields of cereals and seed cotton, but has seemed to prove beneficial in most cases with the legumes grown on soils of this section to which lime has not been added in recent years."

Crop rotations are considered necessary in the management of these soils to build up a permanent system of fertility and three, four, five, and six-year rotations are outlined.

Moisture relation of Texas soils, G. S. FRAPS (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 1, pp. 31-33).—Three years' percolation experiments in galvanized iron cans with 4 clays and clay loams and 4 sands and sandy loams, each being subjected to six different treatments, brought out the fact that the clays

and clay loams show little appreciable saving of moisture due to cultivation or the application of manure under Texas conditions, there being very little more percolation from cultivated and manured pots than from bare uncultivated pots. On the other hand, the sands and sandy loam soils showed a decided gain in moisture with cultivation and manuring, the increased percolation indicating decreased evaporation resulting from both treatments.

Lavas of Hawaii and their relations, W. CROSS (*U. S. Geol. Survey, Prof. Papers No. 88 (1915), pp. 97, pls. 4*).—This report describes and discusses the petrography of Hawaii. It contains information of importance in the study of lava soils, especially those of Hawaii.

Soil investigations in the Lüneburg Heath region, A. ALBERT (*Ztschr. Forst u. Jagdw., 44 (1912), Nos. 1, pp. 2-10, pls. 3; 3, pp. 136-153, figs. 2; 6, pp. 353-364; 11, pp. 655-671, fig. 1; 45 (1913), No. 4, pp. 221-237, pl. 1; 46 (1914), No. 2, pp. 82-90*).—A series of investigations of the physical, chemical, and biological properties of the sandy soils of the heath districts of northwest Germany, with reference to the forestation of waste portions, is reported.

These soils are of two classes, namely, the gray or bleached sands and the brown sands. The bleached sands consist of a leached-out surface soil and a hard impervious subsoil resembling ortstein, which is formed by the leachings from the surface soil. This impervious layer varies in color from rust red to brownish black, varies in depth from about 12 to 14 in. in diluvial sands and from about 20 to 39 in. in alluvial sands, and frequently runs into an extensive layer of boulders. The brown sands occupy the higher elevations and have a higher content of fine matter than the gray sands. The topsoil does not have a leached-out appearance, the hardpan subsoil is usually absent, and no sharp transitions occur between layers. The sand grains are covered with a brown layer consisting of iron and humus compounds.

Shallow cultivation, crop rotations consisting of legumes followed by rye or potatoes, and artificial fertilization are suggested as being the proper treatments for both of these soils before tree planting.

The vertical soil zones in mountainous Russia, W. P. SMIRNOFF (*Internat. Mitt. Bodenk., 4 (1914), No. 4-5, pp. 405-417, fig. 1*).—This article discusses the theory of the zonal distribution of soil types in Russia proposed by Dokouchayev (*E. S. R., 12, pp. 704, 807*), and reports the general results of a soil survey made in Turkestan and Altai in which particular attention was paid to the vertical distribution of the types. It was found that the theory proposed by Dokouchayev is, with slight modifications, applicable to the scheme of vertical distribution in the Altai region. The opinion is expressed that the common laws governing the life of a soil type will hold good several thousand feet above sea level and that when clearly defined for a certain region will afford a safe basis for further study of soil types.

Chemical composition of the alluvial soils of the Falcat basin, Eritrea, A. MAUGINI (*Agr. Colon. [Italy], 9 (1915), No. 1, pp. 1-24, pl. 1*).—Studies of the origin and physical and chemical properties of the soils of this region are reported, and the possibilities of their agricultural utilization, especially by the aid of irrigation, are discussed.

The soils are of alluvial origin, are of considerable depth, very uniform in texture, and contain a high percentage of fine particles. Their physical structure is in most cases favorable to cultivation and their permeability varies according as the sandy or clay particles predominate. In the more compact soils capillary action is very intense during dry seasons. Most of the soils are deficient in calcium carbonate but contain considerable organic matter and phosphoric acid and potash, chiefly in insoluble condition. They are also more or less highly impregnated with soluble alkali salts, of which sodium and

magnesium chlorids predominate. The deficiency in calcium carbonate and the presence of quantities of soluble salts are thought to retard bacterial activities in the soil, especially with reference to the transformation of organic matter.

As regards alkalinity the soils are divided into two classes, viz., those made alkaline by sea water and those characteristic of alkaline soils in arid regions. The sodium chlorid content of the soils was found to vary within wide limits, according to the elevation, stratification, and physical structure of the soil. Near the sea the salt content increased with the depth, while the reverse was true with other soils subjected to annual inundation.

The relations between irrigation and alkali accumulation are also discussed and conditions in the basin are compared with similar conditions in this and other countries. It is stated that the irrigation of these alkali soils with the more or less salty Falcat water presents a problem which can only be solved by proper drainage and cultural treatment.

Investigations on usar land in the United Provinces, J. W. LEATHER (*Allahabad, India: Gort., 1914, pp. 88, pls. 68, fig. 1*).—This report, in three parts, contains the results of investigations into the characteristics of certain classes of alkali land in the United Provinces in India.

The first part deals with unproductive irrigated soils in the neighborhood of Bhadan. These soils were found to contain a certain amount of sodium carbonate and bicarbonate but no other alkali salts, and are water-logged to a depth of about 7 to 9 ft. The results of the investigation seem to indicate that the alkali in the soil is a product of the soil itself and is not deposited by the canal water. It is thought possible to reclaim some of these lands by lowering the ground-water level and maintaining about 2 ft. of water on the surface for a period of six months or a year.

The second part reports experiments on the reclamation of alkali soils. The application of gypsum was the only really effective method of reclamation tested, and the cost of this was prohibitive. Deep and thorough cultivation with heavy manuring was unsuccessful and scraping off the salts was found to be practically useless.

The third part reports comparative investigations of alkali soils under canal and well irrigation. The conclusions drawn are that "in respect of frequency, infertility, nature and amount of salts, or physical condition, there is substantially no difference between the soil of the usar [alkali] patch which has been under canal irrigation for many years and that which has never been subject to this influence at all."

Descriptions of the methods of investigation employed, tables of analytical data, and maps and charts are appended.

Description of the soil types within the boundaries of the "Banjoemas" residency, Java, P. W. HOUTMAN (*Meded. Proefstat. Java-Suikerindus., 5 (1914), No. 2, pp. 13-28, pls. 7; Arch. Suikerindus. Nederland, Indië. 22 (1914), No. 50, pp. 1791-1806, pls. 7*).—This report briefly describes the geography and geology of the residency, and discusses the soils mainly with reference to origin and physical and chemical properties. These are divided into seven groups and consist of volcanic and alluvial material, silts, and clays having textures varying from heavy to light, and lateric formations.

Tables of analyses and soil maps accompany the report.

Recent soil investigation in the Cape Province, C. F. JURITZ (*Agr. Jour. Union So. Africa, 5 (1913), No. 6, pp. 856-870; 6 (1913), Nos. 1, pp. 38-49; 2, pp. 337-345; 3, pp. 455-461; 5, pp. 785-791; 6, pp. 934-939; 7 (1914), No. 1, pp. 62-67*).—This article reports the results of additional investigations of the soils of Cape Colony (E. S. R., 20, p. 1014). Analyses of about 272 soil samples col-

lected from 36 districts are reported and discussed, mainly with reference to physical and chemical composition.

The improvement of lands and intensive exploitation of the soil, E. CATZEFLIS (*Bul. Union Agr. Égypte*, 11 (1913), No. 101, pp. 244-249; 12 (1914), Nos. 102, pp. 11-17; 105, pp. 117-122).—This article discusses the economic aspect of the physical, mechanical, and chemical improvement of the soils in the northern part of the Egyptian Delta.

A study of some physical properties of soils, R. TRNKA (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 363-387, figs. 3).—The results of studies of methods of determining volume weight and porosity of soils are reported.

It is pointed out that methods of determining volume weight in which the original soil structure has been disturbed are usually inaccurate, and it is concluded that the method worked out by the author and A. Slavik of determining volume weight by the water displacement of a clod in original condition which has been given a waterproof coating by dipping in melted paraffin is more nearly exact and more practicable. On the ground that the determination of porosity depends on the correct determination of volume weight and specific weight, it is further concluded that the method of using a paraffin coated clod in natural condition should also be applicable for determining porosity.

An apparatus for accurately measuring water displacement is described.

The adsorptive power of soils, P. ROHLAND (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 393-404).—Substantially the same views are expressed in this as in previous articles along the same line (E. S. R., 31, p. 514; 32, p. 318).

On osmosis in soils, C. J. LYNDE and J. V. DUPRÉ (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 1, pp. 15-19, fig. 1; *Proc. and Trans. Roy. Soc. Canada*, 3, ser., 8 (1914), Sect. III, pp. 133-138, fig. 1).—This article reviews previous work on osmosis in soils (E. S. R., 29, p. 124), and reports further experiments in which a column of very fine soil was used as a semipermeable membrane and a concentrated soil solution as the active solution.

With a column of soil approximately 2.5 in. deep an osmotic pressure equal to the pressure exerted by a column of water 11.5 ft. high was observed. "The results indicate that the pressures observed are not due to the swelling of the soil column . . . [but] are due to osmosis as follows: (1) The semipermeable membranes used in investigations on osmotic pressure are colloids, (2) there is strong evidence that the action of semipermeable membranes is one of unequal absorption. One liquid is absorbed more readily than the other and the movement is toward the liquid least absorbed."

The consistency curves of mineral soils, S. JOHANSSON and A. ATTERBERG (*Internat. Mitt. Bodenk.*, 4 (1914), No. 4-5, pp. 418-431, figs. 13).—In continuation of work along the same general lines (E. S. R., 28, pp. 320, 620), studies are reported of different mineral soils with reference to their consistencies with variable water content. Twenty-five so-called consistency curves showing the water content and the corresponding consistency are given and discussed.

At approximately the middle of each curve is found a sharp knee and from this the curve extends in both directions in the form of a hyperbola. The position of this knee with reference to consistency varies for different soils, being highest for the clays and lowest for the loams. To the left of the knee the curve rises rapidly as it approaches the ordinate or consistency axis for the heavy loams and clays, while for the lighter soils it is more nearly parallel to the abscissa or water content axis. To the right of the knee the curve is the longest for clays and the shortest for loams.

These consistency curves indicate at what water content a soil is most easily tilled. They show that most loams are tillable at all water contents from zero to 14 or 20 per cent and that only the heaviest loams are not tillable

when dry. The less plastic clays may be classed with the heavier loams and may be tilled with a water content of from 5 to 13 per cent, but require relatively more power than the loams. The highly plastic clays can be tilled only with high water content and in that condition are too soft to permit good work.

It is further pointed out that the knee of the curve corresponds to the shrinking limit of soils on drying.

Further studies of consistency curves with reference to soil classification are to be made.

Some dynamic processes in soils in the region of the distribution of frozen soils, K. NIKIFOROV (*Pochvoúčēdēnič (Pédologic), No. 2 (1912); abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 5, pp. 456, 457*).—This article describes certain peculiar phenomena connected with the escape of water resulting from summer thawing. This water accumulates between different layers of the soil, and when the winter freezing begins the increased pressure upon the localized water-bearing areas forces the water to the surface either gradually through outcropping of ice or rapidly with the bursting of the upper frozen layer. In either case the properties of the soil are more or less profoundly affected.

Soil analysis, C. T. GIMMINGHAM (*Jour. Bath and West and South. Counties Soc., 5. ser., 8 (1913-14), pp. 142-147; Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1913, pp. 103-107*).—This article discusses the practical value of soil analysis to the agriculturist and horticulturist and indicates some of the considerations which must be taken into account by the analyst.

Relation of chemical composition to soil fertility, G. S. FEAPS (*Jour. Amer. Soc. Agron., 7 (1915), No. 1, pp. 33-36*).—It is stated that experiments at the Texas Experiment Station indicate that there is a relation between the total nitrogen and the active (soluble in fifth-normal nitric acid) phosphoric acid and potash of the soil and the soil deficiencies as shown in pot experiments.

Alkali in soils, J. W. PATERSON (*Jour. Dept. Agr. Victoria, 11 (1913), No. 5, pp. 288-299, figs. 6*).—The common alkali salts occurring in soils are described and remedial measures discussed, particularly the use of gypsum for black alkali and proper land drainage for white alkali.

Organic matter in soils (*Indian Tea Assoc., Sci. Dept. Quart. Jour., No. 2 (1914), pp. 55-64*).—In this article the changes undergone by organic matter in the soil and the effects produced in the soil by these changes are discussed.

With reference to tea culture it is stated that fine textured soils containing over 50 per cent of silt, fine silt, and clay should contain about 10 per cent of organic matter. Coarser textured soils containing over 50 per cent of coarse and fine sand require not less than 5 per cent of organic matter.

It is also stated that an abundance of organic matter in a soil is likely to prevent attacks of white ants.

On nitrification: Preliminary observations, E. R. ALLEN and A. BONAZZI (*Ohio Sta. Tech. Bul. 7 (1915), pp. 42, figs. 6*).—So-called physiological studies of the nitrifying bacteria of soils are reported, together with brief reviews of the work of others bearing on the subject. A bibliography is appended.

In experiments on the nitrifying power of soils taken from representative plats at the station to determine the effect of soil treatments in cropping, it was found that the nitrifying power of naturally noncalcareous soils was rather feeble as compared with naturally calcareous soils, even after receiving moderate applications of ground limestone, but that very heavy applications of ground limestone imparted a high nitrifying power. The results of these experiments are also taken to indicate that the nitrifying power of the soil may or may not correlate with its crop-producing power, it being considered pos-

sible that the conditions limiting the growth of higher plants in one case may be different from those in another. Continuous cropping, especially without fertilization, reduced the nitrifying power of the soils. "Although the possibility of the production of toxic material is not eliminated, it seems that in the plots studied the deleterious effects of continuous cropping on higher plants, as well as on the bacteria, are closely connected with the nitrogen relations."

The results of nitrification studies in solutions, using the Omelianski solutions to which were added portions of greenhouse soils from the station, indicate that the organisms producing nitrification in these soils are *Micrococcus nitrificans* and *Bacillus nitrificans*. The growth of the nitrite formers was much more feeble in solution than was that of the nitrate formers. Aqueous extracts of ignited and nonignited soils used when reinforced by the regular mineral nutrients possessed no superiority over Omelianski's nutrient solution for the growth of the nitrate producer.

The results of nitrification studies in porous media led to the conclusion that soil, particularly ignited soil, as a medium possesses the property of supporting nitrification better than sand.

A critical consideration of the present methods of studying nitrification led to the conclusion that "the methods in vogue for studying the process of nitrification . . . contain many errors, which must be largely eliminated before the problem of soil bacteriological differences can be satisfactorily attacked."

Action of oligodynamic elements on the nitrifying bacteria, C. MONTANARI (*Staz. Sper. Agr. Ital.*, 47 (1914), No. 6, pp. 441-448).—The author briefly reviews the work of others bearing on the subject, and reports experiments on the effect of the dioxid, sulphate, and carbonate of manganese on nitrification in different soils treated with ammonium sulphate.

Nitrification was apparently stimulated in the soils treated with the dioxid and carbonate of manganese, particularly in the case of a sand washed with hydrochloric acid and distilled water. Manganous sulphate stimulated nitrification much less than the other manganese compounds and was often detrimental.

As a result of further experiments, the stimulation of nitrification by the dioxid and carbonate of manganese is attributed to the oxygen introduced directly by the former and indirectly by the latter rather than to any catalytic action of the element manganese.

Note on nitrification in the peat soil in the vicinity of Laon, Coquidé (*Compt. Rend. Acad. Sci. [Paris]*, 160 (1915), No. 7, pp. 253-255).—Several plats of uncultivated peat soil in natural condition were fertilized with different combinations of potassium chlorid, kainit, sodium nitrate, and slag to determine the effect of fertilization, particularly with nitrates, on the natural vegetation.

Each fertilizer when used alone had an effect on the vegetation, but nitrates were especially effective in increasing the growth. Favorable results were obtained with mixtures containing the three fertilizing elements, but where nitrate was excluded the results were unsatisfactory.

Observations on the formation and layer distribution of nitrates in soils with different nitrogen fertilizers, V. I. TKACHENKO (*Khoz'âistvo*, Nos. 37-40 (1912); *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 6, p. 585).—In a study of the amount and distribution of nitrates at different depths in the soil from June 27 to September 9, 1911, and from April 8 to May 10, 1912, it was found that the minimum amount of nitrate was present in the latter part of August and the earlier part of September, but no direct connection between nitrate and temperature and moisture was observed.

Fertilizing with nitrate of soda in general increased the nitrate content of the soil, but not in all cases. Cyanamid and ammonium sulphate increased the ac-

cumulation of nitrates in the soil to a greater extent than sodium nitrate. There was little leaching of nitrates during rainy periods and this was not noticeable in any case below 25 to 50 cm.

The observations in the spring of 1912 were made on the same plats used in the earlier experiments which had in the meantime been seeded to winter wheat. In general, considerably less nitrate was found than during the preceding summer. The loss of nitrates by leaching was less pronounced on plats fertilized with nitrogenous materials and which, therefore, had a heavier growth of wheat.

The prevention of loss from manure heaps in winter and early spring, E. J. RUSSELL and E. H. RICHARDS (*Jour. Bd. Agr. [London]*, 21 (1914), No. 9, pp. 800-807, fig. 1; *abs. in Jour. Soc. Chem. Indus.*, 34 (1915), No. 2, p. 93).—Observations were made on the losses of nitrogen and phosphoric acid in heaps of manure stored in the open and under shelter.

Of two heaps stored in the open, one lost 25 per cent of its nitrogen from January to April and the other 33 per cent of its nitrogen from November to May. The loss of nitrogen fell most heavily on the easily available portion, that is, the ammonia and the amids. There was a loss of about 8 per cent of the phosphoric acid. In the case of the manure stored under cover, the loss of nitrogen was 6.9 in one case and 7.9 in the other, and there was no loss of phosphoric acid.

The experiments indicated that rain was the most potent source of loss. That the loss is not due to leaching was shown by experiments in which the manure heap was artificially watered but not to the extent of causing increased leaching. The artificial watering caused a large loss of nitrogen as compared with the unsprinkled manure heap.

The conclusion is reached that the loss of nitrogen from an exposed manure heap is not due to volatilization of ammonia to the extent that it is generally supposed to be nor entirely to leaching, but that a considerable proportion of the loss is due to the fact that nitrates are formed on the surface of the manure; these nitrates are washed down by the rainfall into the interior of the heap and are rapidly decomposed with the escape of free nitrogen. Observations are also reported which indicate that considerable loss in nitrogen results from any turning over or moving of the manure heap, but the cause of this was not established.

The results in general indicate that losses in manure can be practically prevented by compacting and storing under cover. They show that the pumping of liquid manure on to a manure heap does not reduce the loss.

Purification of sewage by aeration in the presence of activated sludge, E. BARTOW and F. W. MOILMAN (*Jour. Indus. and Engin. Chem.*, 7 (1915), No. 4, pp. 318-320, figs. 3).—This is an account of experiments carried on in the laboratory of the Illinois State Water Survey at the University of Illinois testing a modification of Fowler's aeration method for the treatment of sewage.

As a result of the treatment there was obtained a sludge containing large numbers of microscopic animals, predominant among which was an annelid worm (*Aeolosoma hemprichi*), which appear to play an important part in the reduction of the sludge. Analyses of the sludge showed 95.54 per cent of water; the dry matter contained 6.3 per cent of nitrogen, 1.44 of phosphorus, and 4 of fat. In pot tests in comparison with an equivalent amount of nitrogen from dried blood the experiments with the sludge showed better growth at the end of 18 days than those with dried blood and much better than those with no added nitrogen.

Can sewage sludge be made valuable as a fertilizer? (*Engin. News*, 73 (1915), No. 12, p. 593).—Brief reference is made to the experiments noted

above in which a practically inodorous sludge of high fertilizing value was obtained by forcing air through sewage tanks.

Analyses of guano, A. HUTIN (*Ann. Chim. Analyt.*, 19 (1914), No. 9-12, pp. 332, 333; *abs. in Chem. Abs.*, 9 (1915), No. 5, p. 684).—Analyses of six samples of guanos recently collected on the Chincha Islands are reported. In these the nitrogen varied from 2.98 to 9.3 per cent, the phosphoric acid from 7.73 to 9.02, and the potash from 2.47 to 4.08.

Prohibition of collection of guano in the Ballestas Islands, Peru (*Riqueza Agr. [Lima, Peru]*, 4 (1914), No. 27, pp. 161-163; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 12, pp. 1565, 1566).—In view of the increasing consumption of fertilizers in Peruvian agriculture and the insufficiency of the supply of guano available for this purpose, the Peruvian Government issued a decree February 5, 1914, prohibiting the exploitation of the guano deposits of the Ballestas Islands for three years, after which period they are to be worked entirely for domestic consumption.

The preparation of fertilizer from kelp, J. W. TURRENTINE (*Amer. Fert.*, 42 (1915), No. 5, pp. 37-42).—This article deals briefly with the distribution, amounts, composition, and fertilizer value of the Pacific coast kelps, and discusses the feasibility from an industrial standpoint of making a fertilizer by drying and grinding the kelp.

The results of the study of composition of the different kinds of kelp common on the Pacific coast indicates that the potassium content of *Nereocystis* is greater than that of *Macrocystis*, and that while the potassium content of the northern kelp is higher than that of the southern there is no marked difference in the iodine content of the two. Proximity to the mouth of a fresh water stream had no appreciable effect upon the potash and nitrogen content of the kelp, and there was no essential difference between the potash and nitrogen content of fronds and stipes. The average of the analyses of wet kelp showed water 85 per cent, nitrogen 0.3, potash 2.5, and phosphoric acid 0.2.

In the author's opinion kelp can, in the beginning at least, be most advantageously prepared for use as a fertilizer by drying and grinding. Methods of preparing such a fertilizer are described and data for the cost of the processes are given.

The utilization of air nitrogen for fertilizing purposes, A. KRAISY (*Ztschr. Ver. Deut. Zuckerindus.*, No. 706 (1914), II, pp. 911-926, figs. 4).—The development of the manufacture of nitrogen compounds from the air is briefly reviewed, and the principles upon which the leading processes for this purpose are based are discussed. A list of factories in operation in 1913 with their estimated output is given.

The cyanamid process, F. S. WASHEURN (*Amer. Fert.*, 42 (1915), No. 7, pp. 21-29).—The recent development and present status of this process are discussed.

The Kalusz kainit, W. KOLSKI (*Ztschr. Landw. Versuchsw. Österr.*, 17 (1914), No. 12, pp. 892-901; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 6 (1915), No. 3, pp. 390, 391).—Numerous analyses showing potash, lime, magnesia, chlorin, and sulphuric acid in the kainit from the Kalusz deposits in Galicia are reported. The potash averaged about 10 per cent, the sulphuric acid 17.5, and the chlorin about 29. Many of the samples contained small amounts of manganese.

Does fertilizing with kainit conserve water? GERLACH and SCHIKORRA (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1915), No. 5, pp. 368-381, 389-393).—Several series of experiments are reported which show that applications of as much as 1,069 lbs. per acre of kainit, which is more than is ordinarily applied in practice, exerted no observable effect on evaporation of water

from the soil and plant, and that absorption of water vapor, by soil was but slightly increased (about 98 lbs. per acre). The evaporation of water from the soil and plant was not influenced by kainit fertilizing, either absolutely or relatively, so long as there was no increase in yield of crop. When there was an increase in yield, however, there was a reduction in the relative utilization of water. This, however, is an effect not confined exclusively to potash salts, but is shown by fertilizing materials in general when an increase of yield results from their use.

The composition of muds from Columbus Marsh, Nevada, W. B. HICKS (*U. S. Geol. Survey, Prof. Paper No. 95-A (1915), pp. 11, fig. 1*).—An investigation of these muds as a possible source of potash is reported.

Analyses of water from wells sunk to varying depths in the muds, as well as of surface muds, indicate the presence of small amounts of potash associated with large amounts of sodium chlorid and other salts, principally sulphates, carbonates, and borates. The high percentages of soluble salts in the muds usually corresponded to low percentages of potash in the salts. "It is believed that a large part of the potassium in the muds has been absorbed from surrounding or percolating solutions and is held in a loosely combined form, probably by colloids. Such a conclusion offers an explanation of the apparent disappearance of the potassium from the brines and saline deposits of the desert-basin regions."

The manufacture of fluosilicates and their use, A. HUTIN (*Rev. Chim. Indus., 25 (1914), No. 295, pp. 188, 189; abs. in Jour. Soc. Chem. Indus., 34 (1915), No. 2, p. 93*).—Attention is called to the fact that most mineral phosphates contain fluorin, which in the manufacture of superphosphate is converted into hydrofluosilicic acid and allowed to go to waste. A simple and cheap method of preventing this waste is described. The method consists essentially of drawing the gases from the superphosphate chamber through a lead-lined tower in which they meet a spray of brine, resulting in the formation of sodium silicofluorid, which can be separated by filtration.

Contributions of the chemist to the fertilizer industry, H. W. WALLACE (*Jour. Indus. and Engin. Chem., 7 (1915), No. 4, p. 281*).—This is a brief statement of the rôle which the chemist has played in building up the fertilizer industry.

AGRICULTURAL BOTANY.

Nutritional physiology of higher plants, V. GRAFE (*Ernährungsphysiologisches Praktikum der höheren Pflanzen. Berlin: Paul Parey, 1914, pp. X+494, figs. 186*).—This book is intended as an aid to laboratory work, and its field lies somewhat between that of the usual laboratory courses in plant physiology, on the one hand, and that of a methodology for biochemical investigations, on the other, dealing more particularly with the chemical and physical phases of the nutritional physiology of plants. It is intended primarily for the use of scientific investigators, and secondarily for scientific agriculturists and students. It covers a wide range of technique related to the factors, processes, and products concerned in higher plant life.

Nutritive exchanges in plants. The rôle of protoplasm, P. MAZÉ (*Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 24, pp. 809-811*).—In order to test the rôle of protoplasm in the nutritive exchange of plants with their external medium, the action of heat on maize and of chloroform on beets was employed. The effects as tabulated are held to show that it is the protoplasm which regulates the nutritive relations of the plant with the external medium, independently of osmosis.

The plurality of starches, C. TANRET (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 13, pp. 530-532).—In continuation of previous studies (E. S. R., 31, p. 828) the author has investigated some of the physical qualities of starch, particularly the effect of heat. Starches derived from 16 different sources were submerged in a water bath at temperatures varying from 35 to 90° C. and also at boiling temperature. The results indicate that starches from different plants vary quite decidedly in their physical attributes.

Some recent work on plant oxidases, W. R. G. ATKINS (*Sci. Prog. Twentieth Cent.*, 9 (1914), No. 33, pp. 112-126).—A critical review is given of recent publications relating to the nature of plant oxidases, their physiological function, distribution in relation to pigmentation, and rôle in plant pathology, and the bearing of oxidase investigations on technology.

Lipase in the germinating coconut, M. L. ROXAS (*Philippine Agr. and Forester*, 3 (1914), No. 2, pp. 33-39).—The results are given of a study in which the author found that lipase was present both as an enzym and a zymogen in germinating coconuts. It occurs mainly in the outer part of the haustorium, smaller amounts being found in the water of the coconut and in the inner surface of the endosperm.

Correlation between the anatomical coefficients of maize and its size and nitrogen content, S. MOSKVICHEV (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 4, pp. 266-281).—From a study of five varieties of maize, the author concludes that cell size shows a positive correlation with height of this plant, but a negative correlation with nitrogen percentage.

The effect of detasseling maize, E. HECKEL (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 16, pp. 595-597).—In a previous publication (E. S. R., 28, p. 225) the author showed that there was a considerable increase in sugar content of the stalks of maize after the removal of the staminate and pistillate flowers. These experiments have been continued with the same general results.

It was noted, however, that all plants did not behave in a uniform manner. In a planting made of giant Serbian maize, while showing in some instances an increase in glucose and saccharose in the stems after detasseling, the average sugar content of the detasseled lot was below that of the check lot grown under similar conditions. Selections have been made of the high-yielding individuals, and breeding experiments are in progress to learn whether increased sugar content can be transmitted to the progeny.

A biochemical study of nitrogen in certain legumes, A. L. WHITING (*Illinois Sta. Bul.* 179 (1915), pp. 469-542, figs. 23; *Bul.* 179, abs. (1914), pp. 8, figs. 2).—After giving a résumé of information relating to the biology of nitrogen assimilation through *Bacillus radicicola*, the author describes experiments conducted to determine through which organs the legumes obtain their nitrogen from the air, and the relative percentages of nitrogenous compounds in the various parts of the soy bean and cowpea at definite periods of growth.

As indicated in the first series of experiments, carried on with soy beans and cowpeas, the plants were grown under control conditions. One lot received a definite proportion of oxygen, nitrogen, and carbon dioxid, a second oxygen and carbon dioxid, while a third received ordinary air. As the result of these experiments it was found that the cowpea and soy bean utilize atmospheric nitrogen through their roots and not through their leaves. Under the conditions of the experiments no combined nitrogen could have been assimilated.

In the second series of investigations the total nitrogen determinations showed that about 74 per cent of the nitrogen of cowpeas and soy beans at the time of harvest is in the tops, while the remainder is distributed between the roots and the nodules. In the earlier periods of growth the roots contain the larger part of the nitrogen. The percentage of soluble nitrogen varies with the dif-

ferent parts of the plant and the period of growth. The nitrogen precipitated by phosphotungstic acid was determined for different parts of the plant, and other forms of soluble nitrogen than those precipitated by phosphotungstic acid and sodium hydroxid were found to occur. Fixation was found to take place at a very early period in the growth of the seedling, sometimes within 14 days, and in some cases was quite rapid, especially with cowpeas. Plants grown under the conditions of these experiments were found to contain no ammonia, nitrites, or nitrates, as measured by the most accurate chemical methods.

The protective action, against magnesium carbonate, of calcium carbonate for *Azotobacter chroococcum*, C. B. LIPMAN and P. S. BURGESS (*Jour. Agr. Sci. [England]*, 6 (1914), No. 4, pp. 484-498).—The authors have studied the effects, separately and together, of calcium carbonate and magnesium carbonate on nitrogen fixation by *A. chroococcum*. They state that while the first is stimulating and never toxic to this organism in concentrations up to 2 per cent in mannite solution cultures, the second is sharply toxic thereto in concentrations above 0.1 to 0.2 per cent in such cultures. While the calcium salt in soil cultures is without effect when present in amounts up to 1.4 per cent of dry soil weight, when it becomes slightly toxic in Anaheim sandy soil, the magnesium is even more toxic in such soil cultures than in solution cultures. The toxic effect of magnesium carbonate is ascribed to the magnesium ion.

Calcium carbonate exercises a protective influence in solution cultures and soil cultures for *A. chroococcum* against the toxic properties of magnesium carbonate. The optimum ratios found of these two components are 6:1 and 15:1 in these two media, respectively, when the absolute values of the two components employed are 1.25 and 0.2 per cent in solution and 1.5 and 0.1 per cent in soil cultures.

Study of the gas exchange and the variation of sugars and glucosids during the course of the formation of anthocyanic pigments in the flowers of *Cobæa scandens*, E. ROSÉ (*Rev. Gén. Bot.*, 26 (1914), No. 307, pp. 257-270).—A brief account of this investigation has been previously noted (*E. S. R.*, 31, p. 427).

Investigations on the penetration of violet and ultraviolet rays in various plant organs, P. A. DANGEARD (*Bul. Soc. Bot. France*, 61 (1914), No. 1-3, pp. 99-103).—The author reports investigations on the penetration of violet and ultraviolet rays through the tissues of various plant organs.

It was found that different species of plants behaved quite differently toward the different wave lengths of the lights, some of the wave lengths readily penetrating leaves, while others were greatly reduced or entirely prevented from passing through. Hairy leaves retarded penetration more than glaucous or smooth ones.

The action of Salton Sea water on vegetable tissues, M. A. BRANNON (*Carnegie Inst. Washington Pub.* 193 (1914), pp. 71-78, pls. 3).—This is a fuller report than that already noted (*E. S. R.*, 30, p. 431), on the anatomical study of dead plants submerged for one to five years in the Salton Sea, on the bacterial study of the water, and on the processes engendered in fresh woods kept in such waters at room temperature.

Woody plants submerged in the Salton Sea were decorticated in about one year. Fresh woods kept in Salton water showed a breaking down in the zone of meristematic cells, but sterilized specimens kept in such water did not decorticate during ten months.

An organism belonging to the *Amylobacter* group was isolated, which produces an enzym capable of hydrolyzing pectins.

Woods emerging annually from 1907 to 1911 showed no breaking down of cell walls in any portion. It is believed that the action of this water on

woody plant tissues is related to hydrolyzing agents of bacterial origin. No evidence of petrification was noted.

The relative action of cold on herbaceous plants, W. RUSSELL (*Bul. Soc. Bot. France*, 61 (1914), No. 1-3, pp. 113-118, figs. 1).—Observations are given on the effect of freezing on herbaceous and semiherbaceous plants in the vicinity of Paris during the winter of 1913-14. This winter is said to have been especially severe, and while perennial plants were not seriously affected, herbaceous ones whose growth had been prolonged late into the fall were destroyed.

The author found that ice formed within plant tissues caused modifications dependent upon the form of the cells. Where the ice occurred in superficial cells, but little injury resulted, but where it was formed deep within the tissues, especially within the vessels and parenchyma surrounding them, the death of the plant usually followed. It was also found that certain cells could continue living for a time although the rest of the plant was killed, and that there could be temporary growth of organs although the members on which they depended were dead.

Further studies of the effects of smoke from towns upon vegetation in the surrounding areas, C. CROWTHER and D. W. STEUART (*Jour. Agr. Sci. [England]*, 6 (1914), No. 4, pp. 395-405).—The authors have extended the studies previously noted (*E. S. R.*, 33, p. 126) by making attempts to measure directly the effects of atmospheric pollution upon trees and upon crops grown on agricultural land near the city of Leeds, and they give some details thereof, with the general effects of air-borne impurities.

In case of trees, individual buds may be injured so that they open late, if at all. Leaves are injured at any stage, but particularly when young, and if they are injured for several successive seasons the tree becomes sickly and gradually dies away, the forms of progressive injury being described. Conifers are more susceptible than deciduous trees, and both are more so than are most farm crops.

As regards cultivated crops, heavier tillage is required in the smoky district. Hedges also are injured and wire fences, metallic roofing, etc., are less durable. The finer and more valuable grasses tend to die out. Young leaves of cereals may redden or bleach at the points, the shoots are thinner, the crops are more uneven in ripening, and the grain is impaired as to appearance, quality, and market value.

The detrimental action of smoke, etc., is at its height in damp weather under conditions favoring accumulation of smoke gases over the growing crops. Quick-growing plants with thick leaves best resist the influence of the smoke. Fruits do not bear well or thrive. Some late vegetables suffer more than early ones. With a few exceptions noted, ornamental flowers die out or fail to do well in this region.

The seed coat of clover, V. FOMINYKH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 15 (1914), No. 4, pp. 294-316, figs. 15).—A study of the seed coats of red clover has led to the conclusion that a thick seed coat is not characteristic of sound and full seeds, but that this character diminishes germinability. A glossy seed coat is an indication of sound and full seed, but this appearance may be impaired or lost by injury in threshing. Ripeness of seed is indicated by a violet or dark blue-green color, which is lost, however, in unfavorable situations, such as excessive moisture. A gray-brown color and shriveling of the seed coats show correlation with quick germination, but not necessarily with high quality of stock.

On the origin of cultivated rice, A. CHEVALIER and O. RÖHRICH (*Compt. Rend. Acad. Sci. [Paris]*, 159 (1914), No. 14, pp. 560-562).—The authors have made a study of rice plants growing in Asia and Africa, comparing the species

growing spontaneously with the forms generally grouped under the name *Oryza sativa* in Asia.

Of the numerous spontaneous species in Asia only one is said to resemble *O. sativa*. From Africa four species are described, some of which are cultivated, that differ in taxonomic characters from the cultivated rice usually referred to *O. sativa*. Among the species described from Africa are *O. latifolia*, *O. breviligulata*, *O. brachyantha*, and *O. longistaminata*.

Plant chimæras, M. SKENE (*Sci. Prog. Twentieth Cent.*, 9 (1914), No. 33, pp. 127-134).—A popular account is given of a number of plant chimæras, or graft hybrids, as they are sometimes called, beginning with *Cytisus adami* and embracing a number of other forms, among them the so-called graft hybrids of *Solanum* produced by Winkler (E. S. R., 21, p. 320).

Spore plants, L. K. ROSENVINGE (*Sporeplanterne (Kryptogamerne)*. Copenhagen: Gyldendalske Boghandel Nordisk Forlag, 1913, pp. 7+388, figs. 513).—This is a discussion, arranged according to class, order, family, and genus, of typical or important thallophytes and archegoniates, with a glossary and index.

Flora of the vicinity of New York, N. TAYLOR (*Mem. N. Y. Bot. Gard.*, 5 (1915), pp. VI+683, pls. 9).—This volume deals with the distribution of the flora of southeastern New York, Long Island, the State of Connecticut, eastern Pennsylvania, and the State of New Jersey. The edaphic and climatic factors are discussed at length.

FIELD CROPS.

Field management and crop rotation, E. C. PARKER (*St. Paul, Minn.: Webb Publishing Co., 1915, pp. 507, figs. 100*).—This book is primarily a text-book, but may serve also as a reference book. It covers the subjects of history, rotations and plans, commercial fertilizers, and experimental evidence, with chapters on soil productivity, soil inoculation, seed selection, fungus diseases, and weeds. A group of problems and practicums concludes each chapter.

A hand chart of farm crops, S. D. SEMENOW (*East Lansing, Mich.: Author, 1915, folio*).—A chart containing data as to time of seeding, method and depth of planting, preparation of seed bed, soil adaptability, time of harvest, average yield per acre, and disease and enemies, compiled for 39 of the more important field crops.

The work of the Huntley reclamation project experiment farm in 1914, D. HANSEN (*U. S. Dept. Agr., Bur. Plant Indus., Work Huntley Expt. Farm, 1914, pp. 23, figs. 8*).—This bulletin reports work in progress (E. S. R., 31, p. 828) conducted by several offices in the Bureau of Plant Industry cooperating with the Montana Experiment Station. Climatic and crop conditions for the year are noted, including plans of the experimental farm and a detailed statement of the numbers of live stock on the project. Yields in crop rotation experiments that include alfalfa, sugar beets, potatoes, oats, wheat, corn, and flax are given.

Results of pasturing hogs on alfalfa show a return of \$76.88 per acre, and on corn of \$62.72 per acre in pork produced. The average net values of the crops of alfalfa and nurse crops from different methods of seeding alfalfa, with nurse crops cut for hay and for grain, early seeding, late seeding, and seeding in 18-in. rows, are, respectively, \$45.68, \$54.46, \$43.86, \$39.96, and \$33.73. The cost of production for the various methods ranged, respectively, as follows: \$34.12, \$32.18 to \$37.86, \$29.04 to \$36.06, \$26.02 to \$33.78, and \$23.23 to \$31.46 per acre.

The results of a time-of-harvesting test show that there were no consistent differences in the yields of the second crop due to delay in harvesting the first crop. On plats where four crops were harvested the total yield was much

greater than the total yield from plats cut only three times. It is noted, however, that the yields of the fourth crop were higher than can be expected in an ordinary season, since the date of the first frost was nearly three weeks later than usual. The determinations of shrinkage of alfalfa cut at different dates "indicate that the amount of shrinkage in the second and third crops was slightly more than in the first. There was no very consistent difference in the amount of shrinkage in the first crop as the length of the growing period increased, although the shrinkage was less in the pair of plats cut last than in those which were harvested earlier. The average shrinkage for the three crops was 76.3 per cent, which is within 0.2 per cent of the average obtained on the same plats in 1913."

Methods of seed production are briefly noted. Of ten methods of eradicating alfalfa, that of plowing from 4 to 5 in. deep when the third crop was about 2 in. high, and floating and replowing from 8 to 10 in. deep six weeks later proved the most successful, the eradication being practically complete, as only two plants per square rod were found the following June, and none by November.

A test of separate pasture grasses showed that "excellent stands of all of the grasses were secured except timothy, Kentucky blue grass, redtop, and western wheat grass. The grasses that produced the best growth and largest quantities of hay during 1913 and 1914 were awnless brome grass, meadow fescue, tall fescue, orchard grass, and tall oat grass." The results of pasturing tests on mixtures of these grasses were very satisfactory. Two cows were carried through the season on three-fourths of an acre.

An experiment with sugar beets covering width-of-row and distance-of-thinning tests showed the highest yields by planting the rows 24 in. apart and thinning to 8 in. in the row, the average yield from this spacing being 18.68 tons per acre as against a general average of 16.89 tons. The control of the sugar-beet root louse was secured to a considerable extent by keeping the soil "wet" during the growing season by frequent irrigations, resulting in a suppression of the insect to about 30 per cent of the plants at harvest time, while on the area not so treated 63 per cent of the plants were infested.

Variety tests of wheat, corn, soy beans, garden peas, irrigation of flax, tests of orchard trees and small fruits, and fertilizer experiments with oats are briefly noted.

It is noted that the methods of reclamation of a tract of very heavy impervious clay and rather excessive alkali content, consisting of green manuring, barnyard manuring, and cultivation, are proving effective.

Breeding of Alpine forms of pasture grasses, T. VON WEINZIERL (*Jahrb. Weidw. u. Futterbaues*, 2 (1914), *Ergänzungsbd.*, pp. 97-192, figs. 39).—This gives results in the breeding and selection of grasses in adaptation and acclimatization work in the Austrian Alps in continuation of work previously noted (*E. S. R.*, 14, p. 349; 30, p. 633). The general development of the work is reviewed, and the methods employed in planting, cultivation, transplanting, selection and breeding, harvesting, and storing are described. Every phase of the work with each variety is fully recorded and a copy of the breeding record sheet of each of the following-named grasses is presented: *Festuca pratensis*, *Dactylis glomerata*, *Arrhenatherum elatius*, *A. elatius* var. *bulbosum*, *Avena pubescens*, *Poa firmula*, *P. serotina*, *Alopecurus laguriformis*, *F. pseudovina*, *F. rubra* var. *genuina*, *F. rubra* var. *fallax*, *F. arundinacea*, *Phleum medium*, *P. michelii*, *P. alpinum*, and *Agropyrum caninum*.

The effect of frequent clipping on total yield and composition of grasses, W. B. ELLETT and L. CARRIER (*Jour. Amer. Soc. Agron.*, 7 (1915), No. 2, pp. 85-87).—This gives results of work carried on at the Virginia Experiment Station in cooperation with the U. S. Department of Agriculture. Data show the

weight of air-dried substance, the percentage of protein, and the total protein content for the product of the various clippings, which were made at from 7 to 30 day intervals.

The results of the experiment, which covers several years, show that "the total yield of dry matter varies inversely with the number of times it is cut during the growing season. The percentage of protein in grass decreases as the grass matures. The decrease in percentage of protein when the grass is allowed to mature is sufficient to more than counterbalance the increase in weight of dry matter. The increase in weight of mature grass over frequent clippings must be fiber and other nitrogen-free substance.

"The cost of haymaking would probably offset the gain in carbohydrates in the case of blue grass, so that land utilized as a permanent pasture should be more profitable than it would be as a permanent meadow. It may be of interest to state that the botanical character of the herbage varied greatly with the frequency of the cutting. On the plats that were frequently clipped blue grass, redtop, and white clover predominated, while on those that were cut less frequently, especially on the one that was cut but once a year, these tame grasses gave way to rank-growing weeds, such as wild carrot, paspalums, yarrow, white-top, etc. This undoubtedly has much to do with the amounts of protein produced."

Laying down land to grass on the Clifton Park system, J. HUNTER (*Chester, England: James Hunter, Ltd., 1915, pp. 32, pl. 1, fig. 1*).—This publication brings together short articles and an address by the author, calculated to show the great value of the Elliot system of farming, previously noted from other sources (*E. S. R., 13, p. 1037; 26, p. 734*).

Universal hay calculator, MOLLIE D. CHESNUT (*Torrington, Wyo.: Author, 1915, pp. [2]+20*).—This shows the tonnage for any given width and over-throw for oblong stacks 100 ft. in length, based on United States Government rule.

Experiments with small grains, J. R. RICKS (*Mississippi Sta. Bul. 171 (1915), pp. 12*).—This gives results of variety tests with oats and wheat, and notes on the treatment for rusts, smuts, and weevils in stored grain. In tests of methods of seeding oats, drilling on a well prepared seed bed was superior to plowing or disking the seed in. Twelve pk. of oats sown per acre gave larger yields than 6, 8, or 10 pk. Suggestions for the production of oats and wheat in Mississippi are given.

Barley investigations, C. P. BULL (*Minnesota Sta. Bul. 148 (1915), pp. 7-47, figs. 12*).—This bulletin discusses barley production in Minnesota, classes of barley grown in the State, methods of planting and harvesting, managing variety tests of barley, methods of improvement of barley, management of the nursery, and methods of cross-fertilization, and gives data showing results of variety tests with about 400 varieties and strains of barley secured from nearly all parts of the world. These include commercial strains, pedigreed strains, and hybrids, under the following classes: Commercial 6-rowed bearded barleys; commercial 2-rowed bearded barleys; pedigreed strains of 6-rowed bearded barleys, each of which has been developed from a single plant of a promising variety; pedigreed strains of 2-rowed bearded barley developed from a single plant; hybrid 6-rowed bearded barleys developed from hybridization, followed by selection from individual plants; hybrid 2-rowed bearded barleys developed from hybridization and selection; and miscellaneous commercial stock. The grain-breeding investigations were in cooperation with the Bureau of Plant Industry of this Department. The range of yields per acre per year for periods of from 1 to 12 years is given for the respective classes as follows: From 48.3 to 51.1

bu., 38.1 to 41.6 bu., 47.7 to 49.6 bu., 36.3 to 38.8 bu., 32 to 41 bu., 34.8 to 39.6 bu., and 30.6 bu.

In breeding for early and late maturity it is noted that "except in the length of the growing period and in the grade of the grain, no striking difference in the average performance of the two selections is shown. A difference of 4.4 days in the length of the growing period for the average of all stocks for the eight years was obtained, while the grade of the grain of the late selections averaged 8.4 per cent better than that of the early selections."

The results from a comparison of improvement by selection and by crossing "show that the average yield per plant of the five crossbred stocks is 0.2 gm. better than that of the five pure lines, while the strength and stiffness of the latter are higher by 5 per cent and 5.6 per cent, respectively. The grade, however, is 4 per cent better for the crosses, which were also slightly earlier in maturing. These differences do not seem to be sufficient to warrant a definite conclusion as to maturity, strength, stiffness, and grade. In yield, the difference, though small, must be given attention. The difference of 0.2 gm. is an average for the individual plant. Assuming that 490,040 plants to the acre are grown under nursery conditions (4 by 4 in. apart), the increased yield on this basis would be 171.6 lbs. or 3.56 bu. to the acre. Under field conditions more plants are grown to the acre, thus reducing the difference of 0.2 gm. per plant, but it is safe to assume that the reduction of difference in yield per plant would be practically compensated for by the increased number of plants. Therefore, from the nursery results it is evident that crossing, even though three years more are required, will prove the better method for ultimate improvement. This does not, however, preclude the value of the pure-line method of breeding, which is undisputed."

Field beans, C. A. ZAVITZ (*Ontario Dept. Agr. Bul.* 232 (1915), pp. 15, figs. 14).—This bulletin considers the statistical status of bean culture in Canada and gives results of variety tests of the small white pea bean, navy bean, and marrowfat bean. Average yields for the past 20 years are given as 17.8, 19.2, and 17.4 bu. per acre, respectively. Cooking qualities, improvement of varieties, anthracnose, and cultural methods are also discussed.

The effect of fertilizers and stimulants upon the growth and production of *Corchorus capsularis*, S. F. ALBANO (*Philippine Agr. and Forester*, 3 (1915), No. 9-10, pp. 218-226).—This records results of applications of barnyard manure, kainit, tankage, and potassium sulphate, singly and in varying combinations, on *C. capsularis* (Chinese hemp).

It is shown that "the application of any kind of manure to *Corchorus* produces a pronounced beneficial effect on the growth of the plant and on the yield of fiber as well. The best result was obtained by the application of a mixture containing nitrogen. Cow dung alone at the rate of 8,000 kg. per hectare [7,120 lbs. per acre] produced as good an effect as kainit at the rate of 2,000 kg. per hectare (taking the average for both sets). The best result was obtained when the plants were set at 20 by 20 cm. [8 by 8 in.] apart; 20 by 40 cm. and 10 by 10 cm. did not give as good a result."

Borax, manganese, mercury, iron, calcium, nickel, zinc, fluorin, and iodine were tried as growth stimulants with varying success on plats of 1 meter square.

"The general conclusion to be drawn from these stimulation experiments is that jute is decidedly less subject to stimulation with various chemicals than are some of the other crops with which experiments have been carried on, most notably, for instance, potatoes and radishes. The only chemicals whose use can be recommended as very likely to be profitable as a result of these tests are iron and very dilute nickel. It remains possible that applications of borax, manganese, and zinc more dilute than any which were tested in this experiment

would also result in an acceleration of growth sufficient to make their use financially profitable."

The physiology of the pollen of *Zea mays* with special regard to vitality, D. I. ANDRONESCU (*Thesis, Univ. Ill., 1915, pp. 36, pls. 4*).—The author shows by numerous tables and plates as results of field and laboratory studies of maize pollen that the chemical composition of the pollen seems to be influenced by selection for protein in the kernels. There is evidence of an increase in size of pollen in an F_1 generation. In certain media maize pollen throws out a protoplasmic expansion. There is considerable difference in the germination of pollen of different varieties of maize, and a great variation in the germination of pollen from different tassels of an unselected or unfixed variety of maize.

Dry heat is injurious to the vitality of the pollen while moist heat can be resisted. Pollen exposed in the laboratory died in two hours, uncovered out of doors it lived four hours, in 60 per cent moisture it lived six hours, in a saturated atmosphere it lived 48 hours, and in hermetically sealed tubes it kept its vitality for 24 hours regardless of external conditions. Pollen from early suckers is as viable as pollen from the parent plants, but that from late suckers gives a low percentage of germination. Low temperature (from 8 to 14° C.) has a stimulative effect upon the vitality of the pollen, including that of late suckers.

Grades for commercial corn, J. W. T. DUVEL (*U. S. Dept. Agr. Bul. 163 (1915), pp. 11, pl. 1, figs. 9*).—This bulletin gives the grade classification of white, yellow, and mixed corn promulgated by this Department, showing the maximum of moisture and other factors; discusses methods of determining the various factors; and describes the sieves, moisture tester (E. S. R., 24, p. 215), and the color plate used in making the determinations.

Cotton cultivation in Italian Somaliland, G. SCASSELLATI-SFORZOLINI (*Agr. Colon. [Italy], 9 (1915), No. 4-5, pp. 193-208, pls. 4*).—This article describes varieties of cotton and methods of cultivation employed in the colony station on the east coast of Africa. Tables show meteorological data, and analyses of soils and of the parts of the cotton plant, fiber, seed, capsule, leaves, stems, and roots.

The world's cotton crops, J. A. TODD (*London: A. & C. Black, Ltd., 1915, pp. XIII+460, pls. 42, figs. 6*).—This book treats of the geographical distribution of cotton, the uses of the fiber and of the seed, and the effects of the war on the industry.

The industrial fiber plants of the Philippines, T. MULLER (*Jour. N. Y. Bot. Gard., 16 (1915), No. 134, pp. 69-79, pls. 2*).—This describes several species of palms, screw pines, grasses, sedges, vines, and other fiber plants, the methods of obtaining the fibers, and their uses.

Notes on hops, 1912-1914, E. S. SALMON (*Jour. Southeast. Agr. Col. Wye, No. 22 (1913), pp. 499-532, pls. 8, fig. 1*).—This describes seedlings of crosses of selected English, German, and American hops and shows the percentage of soft resins in individual plants derived from the various crosses.

A new variety of hop, the "foundling," E. S. SALMON (*Jour. Bd. Agr. [London], 22 (1915), No. 2, pp. 136-140, pls. 3*).—This describes a new variety of hop found at Wye College. It has been thoroughly tested since 1908 and is noted as having good cropping qualities; high resin content; marked resistance to, if not total immunity from, the "nettle-head" disease; and lateness of season.

Influence of color of seed potatoes on the yield, R. SCHANDER (*Illus. Landw. Ztg., 35 (1915), No. 35, pp. 229, 230*).—This gives results of experiments in 1914 that indicate the influence of color on the yield and vigor of the crop. Larger yields were noted for the dark-colored tubers in the variety Wohltmann.

Sugar beets: Preventable losses in culture, H. B. SHAW (*U. S. Dept. Agr. Bul. 238 (1915), pp. 21, pls. 8, figs. 5*).—This bulletin points to striking differences in local yields of sugar beets caused by imperfect stands in the fields. Results are given of observations on three types of soil (deep, sandy loam, well manured and in excellent tilth; very light sandy loam, generally well manured and in good tilth; and heavy black loam, moderately well manured and in fair tilth) in Utah sugar-beet districts, covering the seasons of 1910, 1911, and 1912.

A definite correlation between stand and yield was found. The factors directly causing a decrease in the number of plants to the acre are arranged in three groups, those occurring in the germination stand prior to thinning, careless and improper thinning and blocking, and those incidental to cultural operations between thinning and harvest. The mean percentage of harvest stand and yield in tons per acre for the respective groups of soils are given as 49.96 and 24.56, 63.71 and 17.68, and 46.76 and 13, and the mean of all the plats as 52.26 and 17.43, respectively.

“These studies were made among fair and good beet growers in an old beet district whose mean yield reached the respectable total of rather more than 17 tons to the acre, while the average for the United States for 1910–11 was only 10.17 tons and that for the State of Utah, where these studies were made, was 11.42 tons per acre. The magnitude of preventable loss incurred by a very large proportion of beet growers must be amazing; in fact, it must exceed the entire cost of raising the crop.”

Fertilizers in sugar-beet culture, E. SAILLARD (*Jour. Agr. Prat., n. ser., 28 (1915), No. 41, pp. 309, 310*).—This summarizes some fertilizer experiments conducted by the laboratory of the Syndicate of Sugar Factories of France since 1901.

It is noted that potassic fertilizers generally gave good results in regard to richness, purity, and yield of sugar beets. When beets of the same variety were given similar cultivation in the same field those rich in sugar contained a less amount of soda. A large application of nitrate of soda, especially if part was applied later, retarded the maturity of the beets and reduced the sugar content. Nitrate of soda, nitrate of lime, and cyanamid gave essentially similar results except that nitrate of lime produced beets a little richer and the cyanamid yielded a little less sugar per hectare. Kainit gave better results than chlorid or sulphate of potash.

Experiments in the fertilization of sugar beets (*Inform. Agr. [Madrid], 5 (1915), No. 100, pp. 150, 151, fig. 1*).—The results of the use of nitrate of soda in combination with potassium and phosphorus showed the yields and net profits to be greater with an application of 300 kg. than with 200 kg. per hectare in the Province of Valladolid, Spain. In similar experiments in the Province of Saragossa, 22,500 kg. of beets were produced per hectare without nitrate of soda, and 25,500, 30,900, and 40,000 kg. with the use of 200, 400, and 60 kg., respectively, of nitrate of soda per hectare.

On the variability of the nitrogen appropriation of the offspring of a single mother beet during the first vegetative year, K. ANDRLÍK and J. URBAN (*Ztschr. Zuckerindus, Böhmen, 39 (1915), No. 6, pp. 235–240*).—This gives results of analyses of individuals derived from a single mother beet.

Tables show that the amount of nitrogen used per plant ranged from 0.5 to 4.75 gm. The amount of sugar per beet ranged from 20 to 120 gm., and the percentage of sugar from 15 to 18.55 per cent. The number of parts of nitrogen found to each 100 parts of sugar ranged from 2.46 to 5.44 for the various individuals. It is noted that the larger the sugar content of the beet the relatively smaller was the quantity of nitrogen appropriated and the reverse.

Bud development in sugar cane, Z. KAMERLING (*Bol. Min. Agr., Indus. e Com. [Brasil]*, 3 (1914), No. 2, pp. 88-99, pls. 8).—Results are reported of a microscopical study of the development of the bud of sugar cane, showing the distribution of glucose, starch, tannic acid, and albuminoids in the growing point.

Administration report of the government sugar cane expert for 1913-14, C. A. BARBER (*Rpt. Dept. Agr. Madras, 1913-14*, pp. 50-52).—This briefly notes the progress in the work of breeding sugar cane at Coimbatore, in which an attempt is being made to cross the hardy cane of north India with the richer local canes. Canes from the seedlings of other crosses are observed to have increased in sugar content and now reach over 19 per cent of sucrose in the juice.

A review of the results of the experiment fields, J. M. GEERTS (*Meded. Proefstat. Java-Suikerindus.*, 4 (1914), No. 27, pp. 541-600, pl. 1, figs. 6; *Arch. Suikerindus. Nederland. Indië*, 22 (1914), No. 25, pp. 911-972, pl. 1, figs. 6).—This discusses the results and methods of calculations.

Variation of flower size in Nicotiana, T. H. GOODSPEED and R. E. CLAUSEN (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 6, pp. 333-338).—This gives results of some 25,000 measurements taken on some pure lines and hybrids of *Nicotiana*, covering a period of about five years at the University of California Botanical Gardens.

It has been shown that when plants first come into flower the spread and length of corolla are greater than the spread and length of flowers produced on the same plants later in the growing season. By removing all flowers from the plant as fast as they go by, it is possible to keep up the flower size to nearly that of the first flowers produced, and in some cases to double the life of the plant. During the period which elapses from the time a flower is fully opened to the time at which pollen is shed, there was noted a considerable increase in the corolla spread and associated with it little or no increase in corolla length.

That there is a differential distribution of flowers on tobacco plants according to size at any given time is shown by the comparative measurements of flowers borne among developing seed capsules on the terminal inflorescence of a plant and those borne on laterals of the same plant. Cuttings growing in the greenhouse produced flowers smaller in spread and greater in length than those on the field plant from which the cuttings were taken. Pot experiments showed that flower size could be distinctly influenced by applications of sodium nitrate, and in a direction parallel to that of the influence on vegetative characters.

“The conclusion seems irresistible that flower size in *Nicotiana* is not so constant as it has been assumed to be, but that it is affected by a number of conditions, and that at least some of these may not affect length and spread in the same manner.”

Parthenocarpy and parthenogenesis in Nicotiana, T. H. GOODSPEED (*Proc. Nat. Acad. Sci.*, 1 (1915), No. 6, pp. 341-346).—This article notes the occurrence of viable seeds of *Nicotiana tabacum* Cuba from flowers that had been emasculated by picking off the anthers near the tops of the filaments, castrated in bud plus the pinching off, with the forceps, of the stigma at the very top of the style, or mutilated by pinching off the stigma in the bud without the removal of the anthers.

The author states that “parthenocarpy is of frequent occurrence in *N. tabacum* Cuba, and parthenogenesis, employing the term to mean the production of viable seed without pollination, is also peculiar to this variety of *N. tabacum*.”

Phylogenetic studies of the varieties of tobacco, G. E. ANASTASIA (*Bol. Tcc. Coltiv. Tabacchi [Scafati]*, 13 (1914), No. 2-4, pp. 51-220, pls. 82, figs. 41; *Appendix*, pp. 3, pls. 56).—A study of the structure and form of the leaf,

stamens, and stigma, and of general types of over 100 selections of tobacco varieties and strains is reported.

Deli tobacco a mixture of types, J. A. HONING (*Bul. Deli Proefstat. Medan*, No. 4 (1915), pp. 29, pl. 1).—This article, printed in both English and Dutch, gives the results of a study of the types of Deli tobacco, and considers the number of leaves, measurements of leaves, height of the stem, and time of flowering. It is noted that leaf number is dependent on environment. Six types of tobacco were distinguished in Deli tobacco.

The chemical composition of the tobacco plant in its various stages of growth, E. PANNAIN (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 11, pp. 1450-1452).—Analyses of the tobacco variety Xanthi Yaka, at various stages of growth as produced at Abruzzi, Italy, are reported.

“These results show that seedlings are richer in ash, nitrogen, and organic acids than half-grown or full-grown plants. In plants before flowering, the apical leaves are richer in ash, nitrogen, and substances soluble in ether and alcohol than the lower leaves, but they contain less nicotin and organic acids. In ripe leaves, the ash content decreases from the basal (first picking) to the apical leaves (fourth picking), and the leaves of the first and second pickings are also richer in nicotin, containing double the quantity of the leaves of the third and fourth pickings. The leaf blades are always richer in nitrogen, nicotin, and substances soluble in alcohol and ether than the ribs, and generally also in ash, but they are poorer in organic acids. The stems and roots contain less ash, nitrogen, substances soluble in ether and alcohol, and nicotin than other parts of the plant, but the roots contain more nicotin than the stems.”

Determination of wheats, K. FLIAKSBERGER (*Trudy Bûro Prikl. Bot. (Bul. Appl. Bot.)*, 8 (1915), No. 1-2, pp. 9-210, pl. 1, figs. 43).—The author has here classified and described 185 varieties of wheat grouped under the following eight species: *Triticum monococcum*, *T. dicoccum*, *T. durum*, *T. turgidum*, *T. polonicum*, *T. spelta*, *T. vulgare*, and *T. compactum*.

Mass selection of spring wheat, A. I. SMEBUM (*Selsk. Khoz. i Lîvsov.*, 245 (1914), June, pp. 226-246; July, pp. 369-382).—Mass selection of spring wheat (*Triticum vulgare lutescens* and *T. vulgare erythrospermum*) was undertaken in 1912 and 1913 at the Saratof experimental station with smooth white spikes of the first and bearded white spikes of the second. These were first selected in the field and the collected ears were afterwards separated in the laboratory into groups. The result obtained in the field was the separation from the wheat of botanical admixtures, i. e., the botanical purification of the basic form of wheat.

In the laboratory the ears were selected by type and classified by size, shape, compactness, distribution of spikes, and formation of scales (glumes); by compactness, the maximum being over 2.2 spikes per centimeter and the minimum below 1.7; and by character of the grain, dividing it into mealy, vitreous, coarse-grained, and mixed. Botanical admixtures found among these heads were the millurum, ferrugineum, and hordeiform, also velutinum.

The results obtained from the work of 1912 and 1913 showed that the effect of selection noticed in the first generation disappeared entirely in the second. A repetition of the selection on the same lines gave scarcely any results whatever. The effect of selection on the first generation is of practical importance only when the generation is immediately put to practical purposes.

Individual selection of *T. vulgare lutescens* and *T. vulgare erythrospermum* gave sharply defined types with determined heredity, from which whole series of generations, differing widely from their progenitors and from each other, were evolved. Thus the wheat, which in mass selection gave no marked groups,

is bound to contain a wealth of varied individuals stable in their heredity and giving rise to new species.

Mass selection permitted a study of the botanical composition of collective forms, the basic types of *T. vulgare lutescens* and *T. erythrospermum*; the division of spikes into types, showing the dominant characteristics of the fluctuations and their variations; the determination of the wide limits of variations in the form of the shape of the spike, showing that each fluctuation might be considered as a sharply defined hereditary variation of an individual type. This showed in the mass a variation of forms which were in reality genotypically hereditary. In regard to compactness, that of *T. vulgare lutescens* was found more stable than that of *T. erythrospermum*, while that of *T. erythrospermum* was more plastic. The increase of yield was greater for the less compact heads than for the more compact ones. However, care should be taken not to lessen this compactness beyond a certain degree as this causes a deterioration in yield under unfavorable conditions of ripening.

It was found that *T. vulgare erythrospermum* has, with all degrees of compactness, a larger grain than *T. lutescens*, thus maintaining its reputation for having better grain than the latter species. Average compactness gives the largest grain.

Are there wheat varieties that are more or less completely self-fertilizing? H. NILSSON-EHLE (*Ztschr. Pflanzenzücht.*, 3 (1915), No. 1, pp. 1-6).—Experiments with three varieties of wheat indicate that some varieties may remain pure while other strains may become more or less cross-pollinated when planted in close proximity.

Yams (*Dioscorea*), R. DE NOTER (*Les Igname. Paris: Augustin Challamel, 1914, pp. 66, figs. 18*).—Already noted from another source (*E. S. R.*, 31, p. 334).

Weeds on the Buzuluk Experiment Field (Samara Province) and in the vicinity, S. BAZHANOV (*Trudy Būaro Prikl. Bot. (Bul. Appl. Bot.)*, 8 (1915), No. 3, pp. 276-293).—It was found that although the seed wheat contained only from 1 to 2 per cent of weed seeds the crop showed as high as 12.7 per cent of weeds. Investigation showed about 3,000 weed seeds per square meter to a depth of 2 in. of soil in cultivated fields. Lists of weed seeds found on both cultivated and fallow fields are given.

HORTICULTURE.

Field book of American trees and shrubs, F. S. MATHEWS (*New York: G. P. Putnam's Sons, 1915, pp. XVII+465, pls. 75, figs. 630*).—This work contains concise descriptions of the character and color of species common throughout the United States, together with maps showing their general distribution. Illustrations of leaves and fruiting parts and of typical tree barks, together with several reproductions of tree studies in water-color, crayon, and pen, accompany the text.

Journal kept by David Douglas during his travels in North America, 1823-1827, edited by W. WILKS (*London: William Wesley & Son, 1914, pp. 364, pl. 1; rev. in Quart. Jour. Forestry, 9 (1915), No. 2, pp. 151-157*).—This journal, which is published under the direction of the Royal Horticultural Society, in addition to describing the author's travels in North America from 1823 to 1827, furnishes a record of various trees, shrubs, and flowers observed in different parts of the country. Particular descriptions are given of 33 species of American oaks and 18 species of *Pinus*. A list of plants introduced by the author is appended.

Colonial plants, H. JUMELLE (*Les Cultures Coloniales.—Plantes Oléagineuses. Paris: J. B. Baillièrre & Sons, 2. rev. ed., vol. 5, 1914, pp. 112, figs. 48*).—This

is part 5 of the author's revised work on colonial plants (E. S. R., 31, p. 235). The present volume deals with the culture, preparation, and utilization of a number of oleaginous plants, including the coconut and other palms, peanut, sesame, castor-oil plant, cotton, and soy bean.

Report on the botanic station for the year 1913, E. J. F. CAMPBELL (*Rpt. Bot. Sta. Brit. Honduras, 1913, pp. 6*).—A list is given of economic, fruit, and other interesting plants that have flowered or fruited during the year, together with a list of recent acquisitions at the station and notes on the various economic plants and fruit trees growing at the station.

Vegetable growing, S. C. JOHNSTON (*Ontario Dept. Agr. Bul. 231 (1915), pp. 68, figs. 34*).—A practical treatise on vegetable growing intended both for amateur and commercial growers. In addition to a discussion of the general principles of vegetable growing, specific instructions are given for the growing, harvesting, and marketing of all the ordinary vegetables.

Tomato tests, O. B. WHIPPLE and L. G. SCHERMERHORN (*Montana Sta. Bul. 104 (1915), pp. 339-347, figs. 5*).—This bulletin gives the data on variety tests of tomatoes that were conducted in 1902, 1906, and in the years 1911 to 1913, inclusive. Some of the earlier work has been previously noted (E. S. R., 19, p. 337). Tests were conducted to determine the best varieties for the higher altitudes of the State and to work out methods of culture which would tend to induce early ripening of the fruit.

The data secured from the work as a whole indicate that tomatoes can be successfully grown in the higher altitudes of the State if started in pots or boxes so that they can be transplanted to the field without seriously injuring the root system. Pruning and training have been decidedly beneficial, both from the standpoint of early ripening and quantity of fruit ripened. Although pruning reduces the total amount of fruit produced when both green and ripe fruit are considered, pruned plats have in nearly every case produced from three to five times as much ripe fruit as unpruned plats. Early varieties should be used, and of those tested Earliana, Chalk Early Jewel, June Pink, and Bonny Best have proved most promising.

The cultivation of watercress (*Jour. Bd. Agr. [London], 21 (1915), No. 12, pp. 1093-1098, pls. 4*).—Popular instructions are given for developing watercress beds, propagation and planting, gathering, and marketing, including also information relative to varieties and the enemies of watercress.

The principles of fruit growing, L. H. BAILEY (*New York: The Macmillan Company, 1915, 20. ed., rev., pp. XIV+432, figs. 186*).—The present edition of the author's work (E. S. R., 9, p. 246) has been completely revised and rearranged, much of the subject matter having been rewritten.

The introductory chapter gives an inventory of fruits and discusses the course of development of a fruit region, the determinants in fruit growing, the outlook for fruit growing, the organizing of the business, and different types of fruit growing. In the succeeding chapters consideration is given to the location and its climate, the tillage and the enriching of fruit lands, the plants and planting, laying out the plantation and its subsequent care, accidents and injuries, the spraying of fruit plantations, and harvesting and marketing the fruit.

Michigan laws for the protection of orchards and vineyards (*Lansing, Mich.: State, 1914, pp. 21*).—A compilation of laws dealing with the protection of orchards, vineyards, and gardens from dangerous insects and diseases, impure insecticides and fungicides, trespass, willful and malicious injury, etc., together with acts to prevent fraud and deception in the packing and sale of fruits and vegetables and an act to authorize and regulate a county agricultural department.

Varieties of tree fruits for New Jersey, M. A. BLAKE (*New Jersey Stas. Circ. 41*, pp. 8).—In this circular lists are given of varieties of apples, peaches, pears, cherries, plums, and quinces that are adapted for the home orchard and for commercial planting in New Jersey. Suggestions are also given relative to age and size of trees to plant and time of planting.

Spring versus fall planting, F. M. CLEMENT (*Ann. Rpt. Fruit Growers' Assoc. Ontario, 46 (1914)*, pp. 51-55, figs. 2).—A brief discussion of the relative merits of spring *v.* fall planting, including results of experiments conducted with plums and pears at the Vineland Experiment Station, Ontario. Six Reine Claude plums and six Bartlett pears were planted in the falls of 1911, 1912, and 1913, and duplicate check rows in the springs of 1912, 1913, and 1914. In every case the difference in growth is thus far in favor of the fall planting.

In connection with this experiment the value of dynamiting holes for fruit trees was tested. The dynamited trees have made less growth than either the fall or spring planted trees. This is attributed to the fact that the trees were planted immediately after the holes were dynamited, the soil subsequently drying out badly.

Spray calendar for Georgia, T. H. MCHATTON and J. W. FIROR (*Ga. State Col. Agr. Circ. 8 (1915)*, pp. 8, fig. 1).—This circular contains directions for preparing spray mixtures, with schedules for apples, peaches, grapes, pecans, and vegetables.

Apple culture in Georgia, T. H. MCHATTON, J. W. FIROR, and C. M. KIGER (*Bul. Ga. State Col. Agr., No. 85 (1915)*, pp. 36, figs. 24).—A popular treatise, discussing the orchard location and site, preparation of the land, laying out and planting the orchard, pruning, cultivation, fertilizers, frost injury, protecting the trees from rodents, and insect pests and fungus diseases and their control. Descriptive notes are given of varieties recommended for different sections of Georgia.

Yields of apple trees at different ages, W. T. MACOUN (*Ann. Rpt. Fruit Growers' Assoc. Ontario, 46 (1914)*, pp. 68, 70-72).—In a previous publication data were given on a number of varieties of apples growing at the Central Experimental Farm, showing the yields of the best yielding trees of each variety from the third until, in a number of cases, the twenty-second year after planting (E. S. R., 27, p. 343). In the present paper the record of these trees has been extended to the twenty-sixth year after planting for a number of the varieties. The data are given with a view to showing the importance of keeping individual tree records.

What does it cost to grow a barrel of apples? M. ELLS (*Canad. Hort., 38 (1915)*, No. 5, pp. 121, 122).—During the past season the author kept an account of three different orchards on different parts of the farm, involving some 32.5 acres with a crop yield of 1,600 bbls. The data secured for the one year showed a cost of production of \$1.32 per barrel.

The cherries of New York, U. P. HEDRICK ET AL. (*New York State Sta. Rpt. 1914, pt. 2, pp. XII+371, pls. 57*).—This is the fourth of the station's monographs on the fruits of temperate North America (E. S. R., 27, p. 40).

Chapter 1 discusses cherries in relation to kindred fruits, the distribution of cultivated cherries, uses, amelioration, and the tree and fruit characters of the cherry. A brief conspectus is given of the edible species of *Prunus* followed by a fuller conspectus of the subgenus *Cerasus* to which cherries belong. Chapter 2 takes up the history of cultivated cherries both in Europe and America. Chapter 3 deals with cherry culture, consideration being given to the extent of the industry, stocks for cherries, cherry climates and soils, blooming dates of varieties of cherries as observed in the station orchard for

the period 1912 to 1914, pollination of cherries, the management of cherry orchards, commercial status of cherry growing in New York, cherry diseases, and insects. Chapter 4 describes in detail the leading varieties of cherries and chapter 5 the minor varieties of cherries. The work concludes with a bibliography and references.

The most important varieties are illustrated in colors and all information that was thought would be helpful in breeding cherries, as well as to students of ecology and of plant distribution, has been included. As in the previous fruit books some prominence is given in footnotes to biographical sketches of persons connected with the development of the cherry industry.

The cherry in Ontario, E. F. PALMER (*Ontario Dept. Agr. Bul. 230 (1915)*, pp. 40, figs. 16).—A popular treatise on cherry culture with special reference to Ontario. It reviews the status of the industry, and discusses the relative importance of sweet and sour cherries; methods of propagation; location and soil; planting; cultivation; fertilization; pruning; picking, packing, and packages; markets; cost of production; insect pests and fungus diseases and their control; and varieties.

The following short articles by Ontario cherry growers are appended: *Cherry Culture*, by G. A. Robertson (pp. 32-35); *Sour Cherry Culture*, by H. Leavens (pp. 35-38); and *Sour Cherry Culture*, by P. E. Angle (pp. 38-40).

Smudging an orchard with native material in Alabama, R. E. MALONE (*Alabama Tuskegee Sta. Bul. 28*, pp. 8).—This bulletin describes a successful experiment in smudging a large peach orchard at the Tuskegee Station as a protection against spring frost. Materials such as peach prunings, pine boughs, sawdust, and tar were used in the smudge piles. Loblolly pine boughs were especially valuable for making a smudge. The author is of the opinion that smudging, in addition to saving the peach crop, assisted in forcing out the bloom early.

Marketing Georgia peaches, C. W. BAXTER (*Canada Dept. Agr., Fruit Div. Circ. 1 (1915)*, pp. 7).—This comprises a concise statement relative to general conditions obtaining in the peach-growing sections of Georgia, together with an account of the Georgia Fruit Exchange and exchange marketing methods.

The use of phylloxera-resistant stock, I, M. BLUNNO (*Dept. Agr. N. S. Wales, Farmers' Bul. 80 (1914)*, pp. 88, figs. 14).—The author reviews the results secured in various countries in using phylloxera-resistant stock for *Vinifera* varieties of grapes, and presents considerable data on the behavior of several varieties grafted on different stocks in New South Wales. A summary is also given of the experience of many growers near Sydney in the use of phylloxera-resistant stocks.

The past and present of American viticulture in Tuscany, V. RACAH (*Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 12 (1915)*, No. 1, pp. 48-68).—This paper consists of a short exposition on the progress of reconstituting phylloxera-infested vineyards in the various Provinces of Tuscany, with special reference to the use and value of different American grape species as resistant stocks.

Papaw and papain, H. F. MACMILLAN (*Trop. Agr. [Ceylon], 44 (1915)*, No. 3, pp. 179-184, pls. 2).—This comprises notes on the botany of the papaya (*Carica papaya*), including a detailed description of the fruit, methods of propagation and cultivation, and the collection, preparation, properties, and commerce of papain.

Pecan growing in Georgia, J. W. FIROR (*Bul. Ga. State Col. Agr., No. 82 (1915)*, pp. 24, figs. 5).—A discussion of pecan culture based upon the literature of this subject, experiences of practical pecan men, and the results of studies and experiments conducted at the college during the past three years.

The introductory portion deals with the present status and prospects of the industry. Information is given relative to varieties, top-working, location, site, soil, fertilizers, planting operations, intercropping and cultivation, cover crops, harvesting and marketing, pecan diseases, and insects.

Citrus fruits, J. E. COIT (*New York: The Macmillan Company, 1915, pp. XX+520, pl. 1, figs. 151*).—An account of the citrus fruit industry, with special reference to requirements and practices in California and similar situations.

The first two chapters deal with the history and development of the citrus industry in the southwestern United States and the geography and climatology of California. The succeeding chapters deal with the botany, gross structure, and habits of growth of the citrus plants; varieties; the citrus nursery; horticultural inspection and quarantine service; improvement of citrus fruits by breeding; judging citrus fruits; selection of site and preparation for planting; planting the orchard; cultivation, fertilization, and cover crops; irrigation; pruning and top-working; frost and orchard heating; picking and packing oranges; picking and packing lemons; blemishes of the fruit and their prevention; by-products; marketing; profit and loss; diseases and their control; citrus insects and their control; insect control by fumigation; and various orchard pests and their control. The concluding chapter is devoted to an extensive bibliography dealing with citrus fruits, their culture, utilization of by-products, etc., and including references to other bibliographies on the subject.

A biometrical study in the variation of acidity and the ratio of total solids to acidity of oranges, S. K. MITRA (*Univ. Cal. Jour. Agr., 2 (1915), No. 7, pp. 245-247, figs. 3*).—As a result of a study of 100 Washington navel oranges of a well-known brand, the author found a wide variation among individual oranges in the ratio of total solids to acidity. Hence it appears important that inspectors' tests relative to the ratio of total solids to acid shall be based on a large number of oranges in each case. In another experiment conducted to determine the differences in the quality of the juice in different parts of the same orange a composite sample of juice taken from basic sections of ten oranges showed a percentage of acidity of 0.98 as compared with 0.9 in a composite sample taken from apex sections of ten oranges. The ratio of total solids to acidity was 13.8:1 in the juice from the basic sections and 15.9:1 in the juice from the apex sections.

The pomegrange, a natural hybrid between the orange and pomelo, L. S. PERKINS (*Jour. Heredity, 6 (1915), No. 4, p. 192*).—A short descriptive account is given of a natural hybrid between the orange and pomelo which appeared in an orange grove at Winter Garden, Fla., and has borne regularly for a number of years. The fruit, although rather tart when it first ripens, develops a distinct orange taste later.

Reference is also made to another hybrid, probably a cross between the pomelo and the lemon, which is of no special value.

Notice to citrus growers (Porto Rico Bd. Agr. Expt. Sta. Circ. 4, pp. 2).—The text is given of the resolution adopted by the Porto Rico Board of Commissioners of Agriculture with reference to the control of citrus canker. The resolution prohibits the entry into Porto Rico of all citrus stocks, buds, scions, seeds, or fruits originating in Florida, Alabama, Mississippi, Louisiana, and Texas.

Plant quarantine regulations (Porto Rico Bd. Agr. Expt. Sta. Circ. 5 (1915), p. 1).—The text is given of regulations, effective in 1915, governing the entry into Porto Rico of nursery stock and other living plant materials from the citrus-growing States of the United States and of citrus nursery stock from foreign countries.

California garden flowers, shrubs, trees, and vines, E. J. WICKSON (*San Francisco: Pacific Rural Press, 1915, pp. 262, pls. 12, figs. 14*).—A popular

treatise on the culture of flowers, shrubs, trees, and vines with special reference to California conditions, including lists of varieties adapted for that State.

Hardy ornamental plants for unfavorable city conditions, L. P. JENSEN (*Gard. Chron. of America*, 19 (1915), No. 5, pp. 234, 235, figs. 6).—A list is given of ornamental trees, shrubs, herbaceous perennials, vines, and climbers which have proved by experience to be adapted for a thickly settled district in St. Louis, where the atmosphere is smoky and sooty. Conifers have failed under such conditions and are not included in the list.

Color grouping for small gardens, ELEONORA ARMITAGE (*Gard. Chron.*, 3. ser., 57 (1915), Nos. 1466, pp. 51, 52; 1476, pp. 191, 192).—In this article the author describes a number of groupings of two or three species, especially arranged for developing color schemes in small gardens during the spring months.

Methods and costs of planting a small park to grass, making paths, and planting hedge, H. R. FERRISS (*Engin. and Contract.*, 43 (1915), No. 14, p. 320, fig. 1).—Data are given showing the labor requirements and cost of constructing walks and planting grass and hedges in a small park.

A B C of gardening, E. E. REXFORD (*New York: Harper & Brothers*, 1915, pp. 115).—A small popular treatise on ornamental gardening, both indoors and in the open.

FORESTRY.

The relation of forestry to the development of the country, R. H. CAMPBELL (*Dept. Int. Canada, Forestry Branch Circ. 11* [1915], pp. 7, figs. 4).—A description of some European forest conditions with special reference to their application to forest management in Canada.

The subdivision of forests, J. S. ILLICK (*Forestry Quart.*, 13 (1915), No. 2, pp. 183-198).—A discussion of the fundamental principles underlying the orderly subdivision of a forest with an example as applied to a portion of the Mont Alto State Forest of Pennsylvania.

Report of the superintendent of forestry, R. S. HOSMER ([*Bien.*] *Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1913-14*, pp. 33-68, pls. 4).—This comprises a report for the period from January 1, 1913, to August 31, 1914, relative to the administration and management of Hawaiian forest reserves, forest extension work by the government, tree planting under corporation and private auspices, and miscellaneous forest work. The report for 1913-14 is followed by a summary of forest work in Hawaii during the period 1904-1914.

During 1913 and 1914 ten new forest reserves were established, making a total of 37 reserves with an aggregate area of 798,214 acres, of which 68 per cent belongs to the territorial government.

Report of the acting superintendent of forestry, D. HAUGHS ([*Bien.*] *Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1913-14*, pp. 69-72).—A brief report supplementary to the above and covering the period from September 1 to December 31, 1914. The text is given of a rule approved by the governor, August 22, 1914, concerning the protection of the watersheds within the Honolulu Watershed Forest Reserve.

During the biennial period 1913-14, 1,183,568 trees were planted in the Territory of Hawaii, largely by corporations.

Report of the forest nurseryman, D. HAUGHS ([*Bien.*] *Rpt. Bd. Comrs. Agr. and Forestry Hawaii, 1913-14*, pp. 73-80, pls. 2).—A progress report for the biennial period ended December 31, 1914, relative to the work at the government nursery, Makiki station, and Tantalus forest, and to the Honolulu watershed planting work.

Annual administration report of the forest department of the Madras Presidency for the twelve months ending June 30, 1914. A. W. LUSHINGTON, H. B. BRYANT, J. S. BATTIE, C. D. MCCARTHY, ET AL. (*Ann. Admin. Rpt. Forest Dept. Madras, 1914*, pp. 100+CLXXIV+22).—This is a progress report on the administration of the state forests in the Northern, Central, Southern, and Western Circles of the Madras Presidency for the forest year ended June 30, 1914, including a summary of progress during the previous five years. All important data relative to alterations in areas, forest surveys, working plans, forest protection, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Philippine dipterocarp forests. W. H. BROWN and D. M. MATHEWS (*Philippine Jour. Sci., Sect. A, 9 (1914), Nos. 5, pp. 413-516, pl. 1, figs. 11; 6, pp. 517-568, pls. 13, fig. 1*).—The authors here present the results of a study of the factors influencing the growth and development of Philippine dipterocarp forests. The subject matter is presented under the headings of a general description of dipterocarp forests, distribution, importance, composition and arrangement of Philippine dipterocarp forests, description of selected areas, plant associations on cleared areas, volume of dipterocarp forests, growth, environmental considerations, effect of cutting in dipterocarp forests, planting, and general considerations of management.

Forests of Japan. N. B. ЕСКВО (*Amer. Forestry, 21 (1915), No. 6, pp. 693-711, figs. 18*).—This comprises the substance of an address delivered before the Society of American Foresters, March 4, 1915. An outline is given of the important forest types and species, together with a short account of forest ownership; the administration, management, and exploitation of the state forests; forest protection; milling operations; reproduction; and forestry education and investigation.

Utilization and management of lodgepole pine in the Rocky Mountains. D. T. MASON (*U. S. Dept. Agr. Bul. 234 (1915), pp. 54, pls. 8*).—An account of lodgepole pine (*Pinus contorta*) in the Rocky Mountains discussing ownership and supply; characteristics of the wood; uses; fire-killed timber; size and contents of various products; annual cut; methods of lumbering; costs and selling prices; charcoal making; the management of lodgepole stands with reference to rotation, methods of cutting, brush disposal, regulating the cut, and reforestation; and protection from fire, insects, diseases, and grazing. A number of volume tables for lodgepole pine are appended.

The management of lodgepole pine. D. T. MASON (*Forestry Quart., 13 (1915), No. 2, pp. 171-182*).—A short discussion of past and present systems of management in the lodgepole pine region of the Northwest.

Life history of shortleaf pine. W. R. MATTOON (*U. S. Dept. Agr. Bul. 244 (1915), pp. 46, pls. 10, figs. 12*).—A detailed account of the shortleaf pine (*Pinus echinata*) with reference to distinguishing characteristics, geographical and economic range, character of stands, size, age, and habit, demands upon soil and climate, light requirements, reproduction, growth, causes of injury, and yield.

The uses of Cornus wood. W. DALLIMORE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform., No. 4 (1915), pp. 179-181*).—This comprises notes on the commercial uses of various species of Cornus wood.

Ash manna. G. MAROGNA (*Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 7 (1915), No. 2, pp. 77-145*).—An account is given of the production, composition, and adulteration of ash manna. Chapter 1 discusses the culture of ash trees, including information relative to varieties, climatic and soil requirements, cultural practices, harvesting, commercial quality, uses, and consumption of manna.

The succeeding chapters deal with the chemical composition and adulteration of manna and methods for analyzing manna. The paper concludes with a bibliography of the subject.

Memorandum on the oil value of some sandalwoods from Madras, P. SINGH (*Indian Forest Bul.* 6 (1911), pp. 11).—Analyses were made of 15 different specimens of sandalwood from trees growing on different kinds of soil. The results obtained appear to confirm the popular belief that the wood of sandal trees growing in dry, rocky, mountainous soil is richer in oil than that of the trees found in the more fertile soils of the plains.

A further note on the oil value of some sandalwoods from Madras, P. SINGH (*Indian Forester*, 41 (1915), No. 4, pp. 123-131).—In continuation of the above noted work, analyses were made of 44 samples of roots and stems of sandalwoods collected from different localities with special reference to variation in oil content.

The results of these analyses, as here presented, indicate that neither elevation, age, nor locality has any definite relation to the oil content of the wood. The only factor which appears to affect the percentage of oil is the soil. This conclusion confirms the previous findings that the trees growing in comparatively good, fertile soil yield heartwood poorer in essential oil than those growing in poor, rocky, gravelly soil.

Prevention of decay in mill timbers, F. J. HOXIE (*Trans. Nat. Assoc. Cotton Manfrs.*, No. 96 (1914), pp. 270-292, figs. 8).—A paper on this subject, with a discussion following in which attention is called to the increasing prevalence of dry rot and other fungus troubles in mill timbers after construction. This is believed to be due largely to the substitution of inferior grades of timber.

The author concludes that specifications for hard pine mill timber based on physics and chemistry are needed in place of the present botanical names which have little significance. Density and resin are suggested as indices of good qualities. Of the several antiseptic treatments which have a record over years of practical service kyanizing with corrosive sublimate appears to be best adapted to mill timber. Other newer materials, such as the fluorin compounds, give promise of usefulness but have not been submitted to long practical tests.

DISEASES OF PLANTS.

Report of the phytopathological institute at Wageningen, 1912, J. RITZEMA BOS (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch.* [Wageningen], 7 (1914), No. 2-3, pp. 25-100, pl. 1).—This report deals with the activities of the institute during 1912 in connection with plant injuries of inorganic source as well as those caused by bacteria, fungi, etc., also injuries due to animals or of undetermined causation.

Report of the botanical laboratory and laboratory for plant diseases, L. LINSBAUER, F. ZWEIFELT, and H. ZUDEREL (*Programm u. Jahresber. K. K. Höh. Lehranst. Wein u. Obstbau Klosterneuburg*, 1913-14, pp. 162-186, pl. 1, figs. 3).—This report includes information obtained during 1913 regarding diseases of pomaceous and stone fruits, grapes, and berry crops, and also on soil infection by plant and animal micro-organisms in the vicinity.

Notes are given on the reaction of plant cells to plant lice.

[Plant diseases in Mauritius], F. A. STOCKDALE (In *Summary of Investigations Made during the Period July 1 to November 30, 1914. Mauritius: Dept. Agr., 1914, pp. 1, 2*).—Among sugar cane diseases, deterioration of the white Tanna variety was ascribed to a bacterium of a species as yet undetermined. Red rot (*Colletotrichum falcatum*) is again reported, from a locality in a district previously affected, attacking the white and striped Tanna varieties only.

Leaf disease of coffee was controlled with Bordeaux mixture.

Leaf diseases of tomatoes have been reported, and a fruit disease ascribed to a species of *Glœosporium* has been under investigation.

No definite results have yet been obtained from a study of a disease which causes the dropping of young peaches.

The transmission of rusts in general and *Puccinia malvacearum* in particular, S. BUCHET (*Bul. Soc. Bot. France*, 60 (1913), No. 6, pp. 520-524, 558-565).—This is a critical review of results and conclusions of Eriksson (*E. S. R.*, 14, p. 770) and Blaringhem (*E. S. R.*, 31, p. 841) regarding the wintering-over of rusts.

Smuts and rusts of grain crops, J. E. HOWITT and R. E. STONE (*Ontario Dept. Agr. Bul.* 229 (1915), pp. 24, figs. 15).—Popular descriptions are given of smuts and rusts of grain crops, together with suggestions for their control so far as definite means are known.

On the appearance of spores and mycelium of rust within the grains of cereals, J. ERIKSSON (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 17, pp. 1194-1196).—Referring to an article by Beauverie on the presence of rust spores in seeds of cereals (*E. S. R.*, 30, p. 241), the author calls attention to the fact that he had already reported their occurrence in 1896, but that he considers their presence abnormal and not of practical importance in the propagation of the rusts. A similar position is taken regarding Pritchard's report of their occurrence in wheat (*E. S. R.*, 26, p. 143).

The efficiency of rust spores contained in seed of grain for the propagation of disease, J. BEAUVERIE (*Compt. Rend. Acad. Sci. [Paris]*, 158 (1914), No. 17, pp. 1196-1198).—Reviewing his own investigations (*E. S. R.*, 30, p. 241) and citing other data, the author considers that the evidence favors the hypothesis that spores within the seed coats of cereals and grasses aid in disseminating rust epidemics. He thinks, however, that if this is not already demonstrated there should be controlled investigations carried out to determine the rôle of the intraseminal spores on the wintering of cereal rusts.

Foot rot of cereals, A. DESMOULINS (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), Nos. 41, pp. 381-383; 42, pp. 394-399).—Discussing the various factors, conditions, and characters associated with foot rot of cereals, the author states that this trouble is of complex and as yet incompletely determined causation. It is recommended that late varieties be employed, these being planted as late as possible and not very thickly, that close rotation of cereals be avoided, that early or rank growth be checked by grazing, etc., and that an active fertilizer be supplied in early spring.

Rusts and smuts of Indian corn (*Agr. News [Barbados]*, 14 (1915), No. 335, pp. 78, 79).—Discussing briefly rusts and smuts of maize in the West Indies, the author states that *Puccinia purpurea* has not been met with in this connection, but that *P. sorghi* (*P. maydis*) was noted on maize in one locality. Species of *Oxalis* are not uncommon, members of this genus being subject to attack by the acedial stage of the fungus in Africa.

Ustilago maydis has not assumed very serious proportions. *Sphacelotheca reiliana* has not yet been noted on maize in this region.

A preliminary investigation on a disease of red clover, P. BACCARINI and G. BARGAGLI-PETRUCCI (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5, ser., 11 (1914), No. 2, pp. 23-96, pl. 1, figs. 12).—The abnormal appearance and structural peculiarities shown by clover affected by a disorder appearing in the valley of the Elsa are described, and the fungi, bacteria, nematodes, etc., found in this connection are discussed. After outlining some infection and other studies carried out therewith, the authors sum up this preliminary study by stating that while investigation has brought into view a number of injurious factors in

connection with this progressive deterioration of clover, the fundamental cause of the trouble has not yet been determined.

A bacterial disease of cultivated mushrooms, A. G. TOLAAS (*Phytopathology*, 5 (1915), No. 1, pp. 51-54, pl. 1).—An account is given of a disease of mushrooms observed in caves in and about St. Paul, Minn.

An examination of discolored portions of the mushrooms showed the presence of bacteria, which were isolated, the causal organism being a facultative anaerobe of the *Pseudomonas* type, corresponding to *Bacterium fluorescens* except for the fact that in dextrose broth the reaction is acid instead of alkaline. Some experiments were conducted for the control of the disease, spraying with a number of solutions and fumigating with sulphur being tested.

The fumigation of the mushroom beds with sulphur before planting the spawn gave absolutely clean mushrooms. This treatment, it is said, costs about 5 cts. per 1,000 cu. ft. and has proved entirely practical.

A common but very serious potato disease in Cuba, R. A. JEHLÉ (*Modern Cuba*, 3 (1915), No. 4, pp. 46-48).—A description is given of the late blight or downy mildew, caused by *Phytophthora infestans*, with suggestions for its control.

Experiments in preventing wart disease of potatoes (*Jour. Bd. Agr. [London]*, 21 (1915), No. 12, pp. 1126-1128).—In a previous publication (E. S. R., 31, p. 842) the use of formaldehyde for the control of the wart disease of potatoes (*Chrysophlyctis cudobiotica*) was recommended. During the summer of 1914 experiments were carried on in a number of places in England to test the value of this treatment, but with unsatisfactory results.

Comparisons were made between formaldehyde solution, corrosive sublimate, fertilizing with sulphate of potash, kainit, salt, superphosphate, etc. These experiments were carried out on land that was known to be badly infected with the fungus, but very little difference was observed so far as the amount of disease was concerned. The plats treated with corrosive sublimate seemed to have had an increased amount of disease.

Experiments on the virulence of *Bacillus solanacearum* against different *Nicotiana* species and varieties, J. A. HONING (*Bul. Deli Proefstat. Medan*, No. 2 (1914), pp. 15).—In continuance of previous work (E. S. R., 28, p. 446) the author studied the alleged immunity of *N. rustica*, claimed by Uyeda (E. S. R., 18, p. 151) to be resistant to bacterial wilt.

Of 200 plants (10 each of 20 types) of *N. rustica* inoculated with *B. solanacearum*, all but one died (a result, moreover, practically duplicated in 6 other species), showing that in Deli, at least, *N. rustica* is nonresistant and useless for hybridizing purposes. No variety of *N. tabacum* proved to be really immune, and only 3 varieties (2 from Manila and 1 Japanese variety) were less affected than were most species of Deli tobacco.

Experiments with plants from seed from widely separated regions showed that the introduction of a larger quantity of bacteria, with their excretion products, reduced the inoculation period greatly and was more fatal, the few plants which resisted (10 out of 278) being inoculated by means of a capillary tube and hence with fewer bacteria. These and other observations raise the question as to whether in a fresh culture all or only a portion of the bacteria are virulent.

It is thought that in Deli the differences in climate and in cultivation are in favor of a greater virulence of *B. solanacearum*, also that foreign varieties seem to promise no better hope of producing resistant varieties than does Deli tobacco itself.

Two new species of fungi in tobacco seed beds, P. A. SACCARDO and B. PEYRONEL (*Bol. Tec. Coltiv. Tabacchi [Scafati]*, 13 (1914), No. 1, pp. 3-6, pl. 1).—

Descriptions are given of *Glauopeziza turricula* n. sp. and *Hyalopus geophilus* n. sp., which have been found occurring in the soil of tobacco seed beds, from which they attack the tobacco plants, sometimes causing serious loss.

A review of investigations of the mosaic disease of tobacco, together with a bibliography of the more important contributions, H. A. ALLARD (*Bul. Torrey Bot. Club*, 41 (1914), No. 2, pp. 435-458).—This review and bibliography of mosaic disease of tobacco, under its various names, covers investigations from 1886 to 1914, concluding with the author's own report already noted (*E. S. R.*, 30, p. 450).

Fire blight, W. H. BRITAIN (*Brit. Columbia Dept. Agr., Hort. Branch Circ.* 23 (1915), pp. 10, figs. 2).—A popular description is given of the fire blight of pears, apples, and occasionally quinces, caused by *Bacillus amylovorus*, with directions for its control. In addition to the trees mentioned above it is known to affect also hawthorn, June berry, and mountain ash.

Fungus and other diseases of the apple and pear, G. P. DARNELL-SMITH and E. MACKINNON (*Agr. Gaz. N. S. Wales*, 25 (1914), No. 12, pp. 1037-1044, pls. 6; 26 (1915), Nos. 1, pp. 51-57, pls. 2; 2, pp. 105-113, pls. 10).—Descriptions and, so far as definite methods are known, suggestions for control are given of canker, bitter rot, Phyllosticta canker, Nectria canker, blight, mildew, crown gall, bitter pit, apple scab, pear scab, black rot, spray injury, frost band, chlorosis, etc.

The toxic action of sulphurous anhydrid on olive blooms, L. PETRI (*Studi sulle Malattie dell'Olivo*, VI. Rome: R. Staz. Patol. Veg., 1914, pp. 65-76, pl. 1, fig. 1).—Continuing previous studies (*E. S. R.*, 30, p. 245), and noting here the results of tests carried out under controlled conditions as regards temperature, moisture, and sulphur dioxid content, the author states that this gas in the concentration of about 1:16,000, while not necessarily hurtful to other parts of the plant, is directly and rapidly injurious to the olive stigma at a relative humidity of 75 to 80 per cent, this effect, however, being lessened by relative dryness of the stigmatic papillæ. Pollen shows much higher resistance to this gas, sepals and petals showing either about the same resistance as do the young leaves, or somewhat less.

The fungus of peach mildew, N. WORONICHINE (*Bul. Trimest. Soc. Mycol. France*, 30 (1914), No. 3, pp. 391-401).—Discussing related literature and detailing his own studies in regard to *Sphaerotheca pannosa*, causing mildew of roses and peaches, the author concludes that the biological and morphological divergencies noted are sufficiently great to warrant the separation of this species into the varieties *roseæ* and *persicæ*, corresponding, respectively, to the host attacked by each.

A disease of gooseberry new to Italy, C. GREPPI (*Riv. Patol. Veg.*, 7 (1914), No. 4, pp. 97-99).—This is a brief note on the outbreak of *Sphaerotheca mors-uvæ* in England and parts of Europe, it appearing at points in Italy in 1913 and 1914, with discussion of measures for its control.

The influence of the medium and of atmospheric factors upon the development of downy mildew, L. MOREAU and E. VINET (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 34, pp. 225-235).—The authors detail and discuss recent observations on downy mildew of the grape, regarding variations in virulence of the parasite and in susceptibility of the host, and the influence of the medium and of atmospheric agents upon the development of the fungus. They discuss also, in this connection, the significance as regards spraying, etc., of these considerations and of recent observations on the temporal and causal relations of the outbreaks with the other phenomena.

Downy mildew and copper sprays, G. HÉRON (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 35, pp. 258-263).—The author gives some results of practical experience in combating *Peronospora* in his own vineyard.

Complete or combined treatments were found to be comparatively inexpensive in comparison with the results obtained. Copper acetate and copper sulphate may be used separately or together. High pressures applied to spraying fluids sufficient to reduce the liquid practically to a fog are found to give more complete access to all portions of both stocks and clusters than do lower pressures.

Spraying in relation to flowering, L. LEBRUN (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 23, pp. 711, 712).—It is stated that in 1913 the injurious effects of copper acetate used as spray on grapevines appeared to be accentuated by the tender condition of the vines owing to their rapid growth and the humidity prevalent at the time of flowering.

Death of mulberry, L. MONTEMARTINI (*Riv. Patol. Veg.*, 7 (1914), No. 3, pp. 65-74).—A discussion, with bibliography, is given of a fatal disease appearing in a slow or rapid form in mulberry and receiving various local names in parts of France and Italy. A systematic inquiry has been instituted among agriculturists in Lombardy and neighboring territory.

Investigations in connection with cacao root disease, A. J. BROOKS (*Rpt. Agr. Dept. St. Lucia, 1913-14*, p. 8).—Experiments are reported of an investigation on the *Rosellinia* disease of cacao, which show that the fungus can live on large pieces of cut branches such as are found after pruning shade trees in cacao plantations. Lime trees planted in an infected area are also liable to attack from the fungus.

Tests made of the fungicide known as "fungal" showed that it was without effect in controlling the disease. From the present information it appears that the only practical method of control is to surround the infected area with deep isolation trenches, thoroughly liming the infected soil, and burning the diseased wood on the spot.

The mycoplasma theory of Eriksson, GERTRAUD HAASE-BESSELL (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 6, pp. 393-403).—The author reports having noted, in case of *Althwa rosea* showing typical hollyhock rust not derived from the so-called mycoplasma of Eriksson (*E. S. R.*, 25, p. 850), the plentiful occurrence of structures apparently corresponding to the secondary promycelia of that author.

A bibliography is appended.

A new disease of chestnut, F. CAVARA (*Riv. Patol. Veg.*, 7 (1914), No. 1, pp. 1-5, figs. 2).—The author describes a disease affecting the lower portions of young chestnut plants, as due to an organism found in connection therewith, which receives the name *Bacterium castanicolum* n. sp.

Bibliography of the chestnut bark disease, R. K. BEATTIE (*Penn. Chestnut Tree Blight Com. Rpt. 1913*, pp. 97-122).—A bibliography of publications relating to the bark disease of chestnut to the end of 1913 is given, about 400 references being included.

A disease of pines caused by *Cronartium pyriforme*, G. G. HEDGCOCK and W. H. LONG (*U. S. Dept. Agr. Bul. 247* (1915), pp. 20, pls. 2, fig. 1).—The authors give a detailed account of their investigations on the fungus *C. pyriforme*, which causes a disease of pines and has for its alternate host plant *Comandra umbellata*.

This fungus is widely distributed throughout the United States and causes considerable injury to different species of pines, being particularly injurious to pines growing in nurseries.

For the eradication and control of the fungus, attention should be given to nurseries, and all diseased pines destroyed, so far as possible. At the same time it will be necessary to eradicate the *Comandra* plants in the vicinity of the nursery beds. Spraying these plants with poison substances, it is thought, might prove efficient so far as nursery control is concerned, but under forest conditions this would probably be too expensive. It is recommended that in badly infected areas all diseased trees should be cut out and destroyed wherever possible, and in lumbering, trees showing cankers of the fungus should not be left for seed trees.

A bibliography of literature referred to is given.

A fungus disease of Hevea in the plantations of Bakusu, VERMOESEN (*Bul. Agr. Congo Belge*, 5 (1914), No. 2, pp. 312-321).—Notes are given of a number of diseases observed in a preliminary survey of the Para rubber plantations at Bakusu.

Root diseases due to *Fomes semitostus* and similar parasites were found to be causing considerable loss. A trunk canker or die-back due apparently to *Diplodia caeaiicola* was also troublesome. A number of other parasitic or saprophytic fungi were noted, among them an undetermined fungus near *Hypocrella* and a species of *Cephaleuros* occurring on the leaves. A species of *Gleosporium* was also found present on branches.

Suggestions are given for the control of the different diseases.

Disease of Para rubber trees in the gardens, W. R. RUTTER (*Ann. Rpt. Bot., Forestry and Sci. Dept. Uganda*, 1914, p. 4).—The occurrence of fungus diseases due to *Fomes semitostus* and *Hymenochate noxia* on Para rubber trees in the botanical gardens is reported. The fungi were traced to old tree stumps and decaying timber left on the land not properly cleared of forest trees.

From experiments noted in a previous report (E. S. R. 30, p. 850), trenching about the trees and the use of lime has been found efficient in keeping the fungus from spreading.

Root disease of Para rubber caused by Sphærostilbe repens, F. T. BROOKS (*Agr. Bul. Fed. Malay States*, 3 (1914), No. 2, pp. 40-43).—The author states that during 1914 several rubber trees were found to have been attacked by the fungus *S. repens*. The trees usually show thin foliage and the branches gradually die back. If the roots are examined the disease may be readily distinguished from those caused by *Fomes semitostus* and *Hymenochate noxia* by the absence of external mycelium and by the presence of characteristic mycelial strands or rhizomorphs between the bark and the wood. It is sometimes claimed that this fungus is saprophytic, but the author states that he has traced it into living tissues where it is undoubtedly acting as a parasite.

Planters are advised to cut out and burn all trees affected by this fungus. While there is said to be no evidence that the fungus spreads by means of subterranean strands to neighboring trees, it is recommended that trenches should be dug about the affected trees to prevent any possibility of underground infection.

Study of Bordeaux mixture, L. SICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), Nos. 33, pp. 211-217; 34, pp. 235-241; 35, pp. 263-266; 36, pp. 289-291; 37, pp. 304-309; 38, pp. 323-327).—A report on a study of the preparation and use of Bordeaux mixture, the reactions and qualities corresponding to given compositions and to changes therein, and the practical preparation and employment of this fungicide under conditions obtaining in the vineyard.

Adherent fungicides, V. VERMOREL and E. DANTONY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 18, pp. 561, 562).—The authors describe two adherent fungicides, one composed of copper acetate to which gelatin is added, and the other of Bordeaux mixture containing casein.

For the preparation of the casein it is suggested that 50 gm. of powdered casein be added to 100 gm. of freshly slaked powdered lime mixed with a small amount of water in the form of a paste. After this has stood for a short period, an additional amount of water may be added until about a liter of liquid is obtained. This is then added to the Bordeaux mixture and is said to increase its adhesiveness very greatly.

In order to obtain the best results with these fungicides the authors recommend that the nozzle should be held as close to the plants as possible. In spraying grapes for downy mildew the clusters should be well covered with the fungicide.

Wetting sprays, V. VERMOREL (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 35 (1914), No. 32, pp. 180-182).—Gelatin has been found to confer upon sprays containing it an excellent spreading and wetting capacity and perfect adherence. Casein proves to be one of the best agents for increasing the wetting capacity of a spray, and to leave almost entirely intact the chemical composition of the copper precipitate, which it is adapted to distribute and fix upon the leaves.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Ninth International Congress of Zoology, held at Monaco, March 25-30, 1913 (*IX. Cong. Internat. Zool., 1913*, pp. 928, figs. 178).—The proceedings of the ninth congress are here presented, the papers being given under the following sectional headings: Comparative anatomy and physiology (pp. 137-268); cytology, general embryology, and protistology (pp. 271-433); systematic zoology and habits of animals (pp. 437-541); general zoology, paleozoology, and zoogeography (pp. 545-595); biological oceanography and plankton (pp. 599-620); applied zoology and parasitology—museums (pp. 623-696); entomology (pp. 699-812); and nomenclature (pp. 815-915).

Zoological record, D. SHARP (*Zool. Rec., 50* (1913), pp. XII+[1328]).—This volume (E. S. R., 31, p. 56) records the zoological literature relating chiefly to the year 1913, but includes entries for 1901-1912 that were received too late for inclusion in the previous volumes.

Infection of man with *Bacterium tularense*, W. B. WHERRY and B. H. LAMB (*Jour. Infect. Diseases, 15* (1914), No. 2, pp. 331-340, pl. 1).—"A case of ulcerative conjunctivitis and lymphadenitis in man is shown to be caused by a minute, capsulated bacterium in all probability identical with *B. tularense*, which was first discovered by McCoy and Chapin in a plague-like disease of the California ground squirrel [*Citellus beecheyi*] [E. S. R., 26, p. 461]. . . . Our findings would seem to indicate that this disease is widespread among rodents. Further, we wish to call attention to the fact that this recently discovered disease of rodents is apparently sufficiently virulent for gray mice (*Mus musculus*) to warrant the presumption that it may some day take its place along with *B. pestis* as a menace to man."

A new bacterial disease of rodents transmissible to man, W. B. WHERRY (*Pub. Health Rpts. [U. S.]*, 29 (1914), No. 51, pp. 3387-3390).—The plague-like disease of rodents previously described by McCoy (E. S. R., 25, p. 249), and found by McCoy and Chapin (E. S. R., 26, p. 461) to be due to a new bacillus (*Bacterium tularense*), has been discovered by the author and B. H. Lamb to be transmissible to man.

Two cases have thus far been observed, both at Cincinnati, Ohio, one a meat cutter, the other a farmer's wife. It was suspected that the disease had been transmitted from wild rabbits since they are the chief variety of wild game sold in the markets and because of reports of hunters that wild rabbits in

Indiana and Kentucky were dying in large numbers. Examinations made of two rabbits found dead on a farm near Vevay, Ind., four miles from where one of the cases came from, showed the gross lesions of the disease and were proved by guinea pig inoculations and bacteriologic examinations to be infected with *B. tularensis*.

The author states that at the time of writing he is engaged in testing out rabbits from Kentucky and Ohio which are in all probability also affected with the same disease; he is inclined to conclude that this rodent disease is widely distributed and that extensive epizootics among wild rabbits occur frequently. "While the human cases on record were both individuals who had handled and dissected wild rabbits and were both cases of conjunctivitis it seems possible that infection may occur through less direct channels and that other types of infection in man may occur. On the basis of animal experiments it seems possible that ulcerative rhinitis, ulcerative or membranous sore throat, gastrointestinal infection, or lymphadenitis secondary to cutaneous infection may occur. Susceptible rodents may be infected by feeding and by the introduction of infectious material into the eye or nose or upon an abrasion of the skin. Experiments on transmission by contact or association have failed in the case of guinea pigs and ground squirrels but a recent experiment was successful in the case of rabbits."

It is pointed out that rodent fleas may possibly convey the infection to man since McCoy and Chapin succeeded in transmitting it among ground squirrels twice by means of 100 to 500 squirrel fleas, respectively.

Discovery of *Bacterium tularensis* in wild rabbits and the danger of its transfer to man, W. B. WHERRY and B. H. LAMB (*Jour. Amer. Med. Assoc.*, 63 (1914), No. 23, p. 2041).—A detailed report of the occurrence of this plague-like disease in the two rabbits mentioned in the paper noted above.

Color key to North American birds, F. M. CHAPMAN (*New York: D. Appleton & Co., 1912, rev. ed., pp. X+356, figs. 840*).—This work, prepared with a view to aiding in the identification of the bird in the bush, consists of an introduction, synopsis of orders and families of North American birds, color key to North American birds, and a systematic table of North American birds. An appendix contains a faunal bibliography (pp. 305-331).

Common corn insects, R. L. WEBSTER (*Iowa Sta. Circ. 23 (1915), pp. 16, figs. 15*).—This is a popular account of the insect enemies of corn in Iowa.

Katydid injurious to oranges in California, J. R. HORTON and C. E. PEMBERTON (*U. S. Dept. Agr. Bul. 256 (1915), pp. 24, pls. 5, figs. 16*).—This bulletin reports studies conducted with two species of katydids, the fork-tailed katydid (*Scudderia furcata*) and the angular-winged katydid (*Microcentrum rhombifolium*).

The amount of injury caused by *S. furcata* increased considerably from 1910, when it first came to attention, until 1912, when it caused a loss in several orchards of a full fourth of the crop. A single katydid may destroy several small oranges in a day, the orange once attacked being invariably rendered unfit for sale. The young katydids are on the trees and actively feeding and the injury usually begins about the time the petals are dropping. The blossom buds are sometimes attacked, a hole being gnawed through the petals to reach the pistils and ovary, which are often destroyed in a considerable number of blossoms. The injured oranges usually have been more than one-third destroyed, or have received one or more holes large enough to admit the head and thorax of the slender katydid nymphs, these holes often extending entirely through the orange. At picking time many of these damaged fruits are conspicuous owing to the clean-cut circular holes in the rind, which vary from the size of a dime to about that of a silver dollar.

The bulletin includes an account of the food plants, life history, and habits, with technical descriptions of the several stages of these katydids.

A small chalcidid belonging to the genus *Anastatus* is the only enemy of the egg discovered during the investigation. This parasite is much more effective in checking the angular-winged katydid than *S. furcata* in orange groves in the San Joaquin Valley.

The angular-winged katydid, while much less important, is also responsible for a certain amount of injury to orange trees. The first instar nymphs of *M. rhombifolium* feed principally, if not wholly, upon the leaf surface, removing merely a chlorophyll layer. Later stages gnaw clear through the leaves, filling them with ragged holes and destroy a larger amount of foliage in proportion to their number than does the fork-tailed katydid. It has never been observed to attack blossoms or fruit. The eggs of this species are also attacked by *Anastatus* sp., it being estimated that 80 per cent or more of all eggs deposited are destroyed.

Spraying experiments conducted and here reported have led to the recommendation of two applications of arsenite of zinc at the rate of 2 lbs. per 100 gal. of water, or two applications of arsenate of lead at the rate of 4 lbs. per 100 gal. of water. The first application should be made, at the latest, immediately after most of the petals have fallen; the second application, from 10 days to two weeks after the first. "If it seems desirable to spray for the citrus thrips also, lime-sulphur should be added to the above at the rate of 2 gal. per hundred, and a third application of lime-sulphur only, at the same dilution, should be made about two or three weeks after the second. The cost of spraying will vary somewhat according to size of trees, cost of labor, team hire, insecticides, etc., but with ordinarily good management will not exceed \$5 per acre."

Control of the changa, S. S. CROSSMAN and G. N. WOLCOTT (Porto Rico Bd. Agr. Expt. Sta. Circ. 6 (1915), pp. 5).—Experiments extending over a period of several years are said to have led to a very easy, cheap, and effective method of destroying this mole cricket (*Scapteriscus didactylus*), accounts of which by Barrett (E. S. R., 14, p. 885) and by Worsham and Reed (E. S. R., 29, p. 557) have been previously noted. This consists in the use of Paris green 2.5 to 3 lbs. to 100 lbs. of low grade flour. This mixture, when placed around the tobacco plant in a shallow trench about 1 in. deep and 3 in. from the tobacco plant at the rate of a heaping teaspoonful to the plant, results in practically 100 per cent stand. Broadcasting before planting at the rate of from 250 to 300 lbs. per acre was also effective. The cost, including labor, is said to amount to \$8 to \$10 per acre. This method can also be successfully employed in protecting other crops.

Aphids or plant lice attacking sugar cane in Porto Rico, T. H. JONES (Porto Rico Bd. Agr. Expt. Sta. Bul. 11 (1915), pp. 19, pls. 2).—This bulletin presents brief accounts of two species of plant lice that attack sugar cane in Porto Rico, namely, *Sipha flava*, to which the name "yellow sugar cane aphid" is applied; and *Aphis setariae*, to which the name "brown sugar cane aphid" is given. *S. flava* occurs on the under surface of the cane leaves, especially those which have begun to bend over, while *A. setariae* occurs at the junction of the leaf sheaths and leaf blades of young cane on the lower surface and on either side of the midrib.

Observations and experiments on the San José scale, S. A. FORBES (Illinois Sta. Bul. 180 (1915), pp. 545-561, figs. 3).—A brief note is given on the life history of the San José scale, including a diagram of annual generations descending from one hibernating female, followed by a report of tests of orchard sprays. The work is summarized as follows:

“Experiments with infested ripe apples show that the San José scale may live and reproduce freely on such fruits plucked from the tree and kept at ordinary room temperatures, and that living young may continue to be born under such conditions during a period of eight weeks. Infested apples taken from cold storage in December gave similar results, young being produced on these apples for 25 days.

“Exact breeding experiments conducted at Urbana in 1906 in a way to distinguish throughout the season the descendants of the first born from those of the last born of each generation, gave two successive generations of the last-born series in the complete year and four such generations of the first-born series. A computation based on data thus obtained yielded a possible rate of multiplication under optimum conditions of 32,791,472 to 1 for the year. This total is only the ninety-eighth part of that of other investigators, who took no account of diminished numbers of generations produced by late-born individuals.

“Spraying operations with various preparations of lime and sulphur and with two brands of miscible oils justify the usual preference for the sulphur solutions, especially because of their more prolonged effect when applied in spring. The homemade solutions were equally effective with those ready-made, requiring only dilution for use. These experiments also illustrate the great advantage of early spraying, before an orchard becomes heavily infested, and furnish evidence that spraying in spring is much more effective than spraying in fall, the ratios of benefit being some 20 per cent greater. The possibility of redeeming and restoring a badly infested orchard and maintaining it in good condition, with one or two sprayings a year, was well established by these operations.”

Food plants of the gipsy moth in America, F. H. MOSHER (*U. S. Dept. Agr. Bul. 250 (1915), pp. 39, pls. 6*).—This is a report upon investigations conducted during the years 1912, 1913, and 1914, with a view to determining the favorite food plants of the gipsy moth. A brief statement is given of the results secured with each plant tested. The work leads to a division of the food plants into four classes: (1) Species that are favored food for the gipsy moth; (2) species that are favored food for the gipsy moth after the early larval stages; (3) species that are not particularly favored, but upon which a small proportion of the gipsy moth larvæ may develop; and (4) species that are unfavored food for the gipsy moth. The species in the first of these classes are at present the dominant species in the woodlands in the area now infested with the gipsy moth, but the encouragement of coniferous growth is recommended, provided the class (1) trees can be eliminated.

The sugar cane moth stalk borer (*Diatræa saccharalis*), T. H. JONES (*Porto Rico Bd. Agr. Expt. Sta. Bul. 12 (1915), pp. 30, pls. 3, fig. 1*).—A summarized account of this borer, which is distributed throughout Porto Rico, its biology, control measures, etc. A report of investigations of the injury by this pest in Porto Rico by Van Dine has been previously noted (*E. S. R.*, 27, p. 659).

Two parasitic enemies occur in Porto Rico, one an egg parasite (*Trichogramma minutum*), the other a tachinid fly, probably *Hypostena* sp. A parasitic fungus (*Cordyceps barberi*) attacks the larva and pupa.

“The preventive methods of control advised to reduce injury by the borer include planting of noninfested seed, simultaneous planting and harvesting of large areas of cane land, and clean cultivation before and after planting. The remedial measures of control include the collection of egg clusters and the cutting out of dead hearts. The burning of trash as a means of reducing injury is not to be recommended and the use of trap lights as a means of capturing the adults does not seem advisable. At the time of harvesting, all stalks cut in the field

should be taken to the mill and ground in order that the numbers of the larvæ and pupæ be reduced."

A bibliography of 14 titles is included.

American plum borer, E. B. BLAKESLEE (*U. S. Dept. Agr. Bul. 261 (1915), pp. 13, pls. 3, fig. 1*).—A report of biological studies of *Euzophera semifuneralis* conducted during 1913-14.

This lepidopterous borer appears to prefer trees that are in a somewhat weakened condition, such as those partially girdled by the disease commonly known as collar blight or mechanically injured by frost. Without injury of some sort to its host plant the borer rarely succeeds in establishing itself, and entirely healthy and uninjured trees are in little danger from its attack. Where a tree has suffered injury the work of this borer may, in many cases, considerably shorten its life. Beginning at some scar, wound, or crevice, where a bark scale offers partial protection, the larva works its way back into the living tissue, in broad, shallow, irregular galleries just beneath the bark. It has been found feeding upon plum, peach, cherry, Chinese plum (*Prunus simoni*), Kieffer pear, mountain ash, persimmon, apple, and Russian mulberry. The author has found it equally abundant on plum, cherry, peach, and apple.

The insect is known to occur in 21 different States as far separated as the District of Columbia, Arizona, and Washington. The species hibernates in the larval stage under the bark scales in a tough cocoon of white silk at the entrance of its feeding galleries. In the latitude of northern Virginia and the District of Columbia in a normal season pupation commences about April 1. In the latitude of Winchester, Va., the adults begin appearing the last of April or first of May. Oviposition commences in from one to three days after emergence, from 12 to 74 eggs having been deposited by moths kept under observation in the laboratory. At Winchester during 1913 eggs deposited the latter part of April and early May required from 8 to 14 days for incubation. Eggs of the first generation apparently begin hatching the early part of May and of the second generation about July 1. Observations at Winchester of larvæ which hatched on May 7 showed a feeding period of 34 days, a prepupal period of 2 days, and a pupal period of 10 days.

The larva has a number of parasitic and predaceous enemies. Two parasites reared at Winchester have been determined as *Idecthis* sp. and *Mesostenus thoracicus*. The former was the more common, some 13.47 per cent. having been parasitized by it. *Itopectis marginatus*, *M. gracilis*, and *Pimpla* sp. were reared from borer larvæ at Fort Valley, Ga., in 1905, and *Tenebrioides corticalis* has been taken feeding upon them.

It is thought that this borer will probably never become a pest of more than ordinary importance, except in occasional isolated cases. When the ordinary precaution of cutting away the dead bark and painting the wounded areas is followed, this may be regarded as sufficient for the control of the borer. Where the borer has established itself already, the cutting out method is the only one that can be followed.

A bibliography of 12 titles is included.

Douglas fir pitch moth, J. BRUNNER (*U. S. Dept. Agr. Bul. 255 (1915), pp. 23, figs. 10*).—It has been definitely determined that in the northern Rocky Mountain and Pacific coast regions the Douglas fir pitch moth (*Sesia nora-roensis*) is responsible for at least 90 per cent of that damage to Douglas fir (*Pseudotsuga tarifolia*), known as pitch seams, gum check, windshake, etc., and the same species appears to be responsible for the similar depreciation in timber that occurs in the southern Rocky Mountain district.

The loss occasioned by the work of this class of insects causes the difference in price between absolutely clear lumber and the lower grades. They work in

a portion of the trunk which later clears itself of branches, hence only logs are affected which, were it not for previous infestation by them, would yield only the better grades of lumber. Douglas fir sawyers estimated a general loss in the entire Douglas fir product of between 7.5 and 15 per cent due to pitch seams. The depreciation is lowest in the Rocky Mountain region and heaviest toward the coast, evidently corresponding to the respectively slower or quicker growth of the trees in the respective localities and to the relative scarcity or abundance of the moth in these regions.

The author presents an account of its life history and habits and of the nature of its injury. A period of three years is said to be required for the development from egg to adult, 30 days being required for the incubation of the egg and a similar period for the pupa. Two generations of larvæ may be found at any time of the year.

In determining control measures readily accessible areas were selected for detailed investigations. The results of the work are said to have made it evident that to accomplish any permanent good under general forest conditions it is best to extend control over large areas. "Destruction of the larvæ is the only remedy that can be used to reduce an infestation. When the infested pitch tube is located, it should be separated from the tree, the thus exposed larva killed, and to insure cleaner healing the ragged edges of the wound should be smoothed with a knife or small ax, after which they should be painted with creosote or a similar preparation, to prevent reinfestation by insects or fungi. The enlarging of the wound by the smoothing of its edges will also leave a pitch blister in the tissues, but the ultimate result will not be nearly as disastrous as from the untreated seifid wound, since a clean healing from the inside obviates much of the chance of its producing a circular seam. Freshly vacated wounds might be treated the same way with profit."

The Hessian fly situation in 1915, F. M. WEBSTER and E. O. G. KELLY (*U. S. Dept. Agr., Office Sec. Circ. 51 (1915), pp. 10, figs. 5*).—This circular presents diagrams which illustrate the seasonal development of the Hessian fly from egg to adult twice during the year and a map showing approximate dates in the fall, in various parts of the country, after which, under normal meteorological conditions, wheat may be sown without exposing it to serious attacks by this pest.

House flies, L. O. HOWARD and R. H. HUTCHISON (*U. S. Dept. Agr., Farmers' Bul. 679 (1915), pp. 22, figs. 15*).—This bulletin, which supersedes Farmers' Bulletin 459 (E. S. R., 25, p. 762), gives particular attention to preventive and control measures.

Further experiments in the destruction of fly larvæ in horse manure, F. C. COOK, R. H. HUTCHISON, and F. M. SCALES (*U. S. Dept. Agr. Bul. 245 (1915), pp. 22, pl. 1, fig. 1*).—This is a report of work carried on in continuation of that previously noted (E. S. R., 31, p. 653).

This bulletin deals with investigations of the larvicidal efficiency of both organic (anilin, beta-naphthol, cresylic acid, para-dichlorobenzene, formaldehyde, nitrobenzene, oxalic acid, and pyridin) and inorganic (arsenical dip, chlorid of lime, Epsom salts, lime-sulphur, and sulphuric acid) substances, together with bacteriological and chemical examinations of horse manure to which many of these substances were applied. Of the inorganic substances tested arsenical dip was the only one which when used in amounts considered practical destroyed the larvæ of the house fly. Of the organic substances anilin, pyridin, and nitrobenzene, when used in certain dilutions, gave satisfactory larvicidal results, but the cost precludes their use.

The larvicidal action of plant material containing saponin (corn cockle [*Agrostemma githago*] and agave [*Agave lecheguilla*]) and alkaloids (blackleaf 40, larkspur [*Delphinium*], stramonium [*Datura stramonium*], and hellebore [*Veratrum album* and *V. viride*]) was tested. Other plant material tested included oxeye daisy (*Chrysanthemum leucanthemum*) and pyrethrum (*C. cinerariaefolium*). Powdered hellebore proved the most efficient and practical of all the substances tested.

"Powdered hellebore, using 0.5 lb. to 10 gal. of water and applying this to 8 bu. of manure, is also an effective larvicide and exerts no injurious action on the fertilizing value of the manure as determined by bacteriological and chemical analyses, and no injurious action on plants has been detected in any of the field tests. Hellebore is used as an insecticide and is obtainable in most cities and agricultural districts. The cost of this treatment is 0.69 ct. per bushel of manure."

Borax, which was shown in the previous bulletin to be an effective larvicide, is obtainable in all parts of the country, and the cost of treating manure at the rate of 0.62 lb. of borax per 8 bu. is 0.42 ct. per bushel. "While borax may be applied to manure at the foregoing rate and the treated manure may be added to the soil at the rate of 15 tons to the acre without injuring vegetation, nevertheless excessive quantities of borax may be applied to manure through carelessness, and injury to vegetation may in consequence result. In the light of this year's experiments it seems advisable to recommend borax as a larvicide for the treatment of outhouses, refuse piles, and all other places where flies may deposit eggs. However, on account of the possible carelessness previously mentioned, and because large quantities of manure are sometimes used by truck growers, it seems best to guard against possible injury to vegetation by recommending powdered hellebore for the treatment of manure, since no injury can arise from the use of excessive quantities, as it is entirely decomposed in the course of the fermentation of the manure."

Plague and plague-like disease.—A report on their transmission by *Stomoxys calcitrans* and *Musca domestica*, N. E. WAYSON (*Pub. Health Rpts.* [U. S.], 29 (1914), No. 51, pp. 3390-3393).—The author reports that the transmission of *Bacterium tularensis* by bites of stable flies occurs, apparently, only from those animals having an advanced stage of the bacteremia. In two experiments where stable flies were allowed to bite the infected animal four times and the healthy animal four times death did not occur, but in two experiments where stable flies were allowed to bite an infected animal eight times and to bite a healthy animal eight times death resulted. Experiments are being conducted to determine the length of time that flies remain infective, the results thus far having been negative after 24 hours from the time of feeding. House flies fed on 48-hour-old viscera of an animal dead of the disease were found to convey the infection.

The cranberry rootworm, H. B. SCAMMELL (*U. S. Dept. Agr. Bul.* 263 (1915), pp. 8, pls. 2).—The cranberry rootworm (*Rhabdopterus picipes*) is the larva of a small brown chrysomelid beetle which has recently become a source of injury to the cranberry in New Jersey. Observations continued through a period of two years indicate that at the present time it is not a pest of prime importance on cranberry bogs, and that its ravages are not to be compared in severity to those of the cranberry girdler (*Crambus hortuellus*).

The chief injury is caused by the feeding of the larvæ on the roots and runners where the latter come in contact with the ground. As a rule only the bark is eaten from the large and secondary roots, the wood occasionally being attacked while the fibrous roots, which are so numerous as to form a dense mat an inch or more in thickness, are completely devoured. The beetles feed on the foliage

and fruit. Although it is widely distributed throughout the United States, having also been recorded from wild grape, myrtle, and basswood, and observed by the author on blueberry and inkberry, previous to its discovery on cranberry it was not regarded as of economic importance. The injury occurs mainly on sandy lands or savannas, where the root system of the vines is not so extensive as on muck or peat bottoms.

"The beetles appear in numbers about the end of June, deposit eggs in the soil, and die before fall. The larvæ feed on the fibrous roots and bark of the larger roots until late fall, when they hibernate in cells formed in the soil. Some spring feeding of the larvæ occurs. Pupation commences early in June, the average duration of the stage being 14.5 days.

"No satisfactory practice in the use of the winter flowage or the spring re-flowage to exterminate an infestation of larvæ or pupæ has been developed. Invigorating the vines by the application of fertilizers or sand promises excellent results."

A list of eight references to the literature is included.

The Calosoma beetle (*Calosoma sycophanta*) in New England, A. F. BURGESS and C. W. COLLINS (*U. S. Dept. Agr. Bul. 251 (1915), pp. 40, pls. 8, figs. 3*).—This account is supplementary to that by Burgess, previously noted (*E. S. R.*, 26, p. 350). Among the phases considered are methods of packing beetles for shipment, the native home of *C. sycophanta* and hosts attacked, equipment used for rearing predaceous beetles, data relating to the life history of *C. sycophanta*, natural enemies, colonization, dispersion, etc. This predaceous beetle has now become firmly established in New England and has already demonstrated that it is a very important factor in the control of the gipsy moth by natural enemies. The results of 1914 indicate that it is the most important single natural enemy of the gipsy moth. It continues to spread each year and in all probability will soon be present throughout the entire territory where the gipsy moth is known to occur.

The Parandra borer as an orchard enemy, F. E. BROOKS (*U. S. Dept. Agr. Bul. 262 (1915), pp. 7, pls. 4*).—This paper relates to *Parandra brunnea*, a cerambycid which has attracted considerable attention during the past few years as an enemy of trees of several widely separated species and of chestnut telephone and telegraph poles. An account of its injury to telephone and telegraph poles by Snyder has been previously noted (*E. S. R.*, 25, p. 51).

The characteristic injury of the insect to trees is in the form of a multitude of tortuous larval galleries extending through a more or less restricted portion of the trunk or larger branches. Its most destructive attacks usually occur in the trunk within a few feet of the ground, the work being followed quickly by decay of the affected wood and frequently by the breaking down of the tree at the point of greatest injury. Cultivated fruit trees are often injured, old apple, pear, and cherry trees being especially liable to attack. Hollow bases and decaying areas and cavities in the trunk and the consequent breaking and falling of weakened trees under the pressure of wind and snow are conditions quite commonly due in a large measure to the work of this insect.

Records indicate that it may be found over the greater part of temperate North America. It is one of several species of borers from which trees are in very little danger of injury as long as they are kept in sound and vigorous condition. It enters the wood from dead or decaying places on the surface and is probably never found in trees whose trunks and larger branches are entirely covered with healthy bark.

The eggs, which are placed in small punctures in the surface wood of dead spots, hatch in from two to three weeks. The larvæ mine throughout the wood for a period of probably three years, extending their galleries upward more

frequently than downward. At French Creek, W. Va., in 1913 and 1914, pupation took place during the last of June and the first of July, from ten days to two weeks being required for transformation to adults.

The author has found the parasite *Odontomerus mellipes* to attack this borer in West Virginia. The first and most important consideration relative to preventing injury by this borer is the keeping of the trees in such condition of soundness that the beetles will not deposit eggs in them. Whenever the borers of this species gain entrance to a tree there is only one practicable way of removing them and that is to gouge or chisel out all the wood through which the burrows extend. After removing all the punctured wood and all the wood soaked with water or affected by decay or disease, the cavity should be sterilized by the application of creosote and filled compactly with a mortar made of one part of a good grade of Portland cement and three parts of clean, sharp sand.

The sugar cane weevil root borer (*Diaprepes spengleri*), T. H. JONES (*Porto Rico Bd. Agr. Expt. Sta. Bul. 14 (1915), pp. 19, pls. 3*).—While this weevil root borer appears to be generally distributed throughout the island, the larvæ seem to cause most serious injury to cane in the lands on the south coast between Guánica and Aguirre. Injury is caused to the root system of sugar cane through pruning off the small roots and by tunneling into the root stocks, which stunts the growth and in cases of severe infestation results in the death of the plants.

“The eggs are laid in clusters between parts of the same leaf or of two leaves, the surfaces about the eggs being held together by an adhesive substance. In the field the eggs, for the most part, seem to be placed on sugar cane and various grasses. The larva or grub enters the soil immediately after issuing from the egg, and it is in this stage that the insect injures the root system of the cane. The pupa, the quiescent stage between larva and adult, occurs in an earthen cell in the soil. Notes on the length of time passed by the root borer in the soil as larva, pupa, and adult are not complete, but it appears that the beetles which develop from eggs laid at any one time are not themselves ready to deposit eggs until about a year later. Apparently there is an overlapping of generations. The beetles live for a considerable time, the females apparently longer than the males. One female collected in the field and kept in confinement remained alive from July 29 to November 8; another from August 15 to November 7. During this time the latter individual deposited 400 eggs.”

The collection and destruction of the beetles and grubs is recommended as the best method of control thus far developed.

A brief account of this weevil by Van Dine has been previously noted (*E. S. R.*, 30, p. 355), as has a systematic study by Pierce (*E. S. R.*, 33, p. 360).

Cone beetles: Injury to sugar pine and western yellow pine, J. M. MILLER (*U. S. Dept. Agr. Bul. 243 (1915), pp. 12, pls. 5, fig. 1*).—Injury to seed of sugar pine throughout California and Oregon and of western yellow pine in the Pacific coast and southern Rocky Mountain regions, termed “blighted cones” and distinguished by the dying of immature cones soon after the starting of the second year’s growth, is caused in large part by small scolytid beetles of the genus *Conophthorus*, particularly the sugar pine beetle (*C. lambertianæ*) and the western yellow pine cone beetle (*C. ponderosæ*). Accounts are given of these two beetles with observations of their biology and the nature and extent of their injury.

Observations indicate that from the last of August until the following May all the infestations within an area will consist of the broods of new adults which are overwintering within the blighted cones. Thus it is evident that if fallen infested cones from the trees which seed in a burned or cut-over area

could be raked up and burned between September 1 and May 1, a very appreciable reduction of the infestation and damage might result. "In the case of sugar pine all infested cones will be found on the ground under the trees during this period and, when the conditions seem to warrant it, burning may be done without great expense. September, October, and November would be the more favorable months for the work, as winter snow and unfavorable conditions for burning will probably be found during the winter and spring.

"Seed collectors in locating areas for collecting may estimate the amount of cone-beetle damage on the trees by July 15, in some situations a month sooner, as the blighted cones by that time begin to stand out conspicuously on the trees. From these estimates the collector may determine whether or not the seed crop of the current year is too badly damaged to be profitably collected."

Porto Rican beekeeping, E. F. PHILLIPS (*Porto Rico Sta. Bul. 15 (1915), Spanish ed., pp. 28, pls. 2*).—A Spanish edition of the bulletin previously noted (E. S. R., 31, p. 354).

The silverfish; an injurious household insect, C. L. MARLATT (*U. S. Dept. Agr., Farmers' Bul. 681 (1915), pp. 4, figs. 2*).—A revision of Circular 49 of the Bureau of Entomology, previously noted (E. S. R., 14, 374).

The entomogenous fungi of Porto Rico, J. R. JOHNSTON (*Porto Rico Bd. Agr. Expt. Sta. Bul. 10 (1915), pp. 33, pls. 9, fig. 1*).—The author here presents descriptions of the known entomogenous fungi of Porto Rico, based upon collections and observations commenced in 1910. These thus described are the aphid fungus (*Acrostalagmus albus*); the brown fungus (*Ægerita webberi*); the Aschersonia group, including the red fungus of the white fly (*A. aleyrodidis*), the top-shaped Aschersonia (*A. turbinata*), the lemon-yellow fungus of the white fly (*A. flavo-citrina* and *Aschersonia* sp.); the mealy bug fungus (*Aspergillus flavus*); the green fungus of the grass worm (*Botrytis rileyi*); the shield scale fungus (*Cephalosporium lecanii*); the Cordyceps group; the Entomophthora group, including the brown-tail moth fungus (*E. ulicæ*), *Empusa* on mealy bugs (*Empusa fresenii*), and *Empusa* on the grass worm (*Empusa* sp.); the Gibellula spider fungus (*Gibellula arachnophila*); the Isaria group, including *Cordyceps barberi* and the white mealy bug fungus (*Isaria* sp.); the green muscardine (*Mctarrhizium anisopliæ*); the black fungus of scale insects (*Myriangium duriei*); the white headed fungus on scales (*Scolecconectria coccicola*); the red headed fungus on scales (*Sphærostilbe coccophila*); and the cinnamon fungus (*Verticillium heterocladum*).

A bibliography of ten titles relating to the subject is included.

Variation in Oxyurias: Its bearing on the value of a nematode formula, S. B. FRACKER (*Jour. Parasitology, 1 (1914), No. 1, pp. 22-30, fig. 1*).—The author finds that the proportionate size of the organs in Nematoda is an important factor in their identification and emphasizes the importance of stating it in the description of new species.

"The locations of the cephalic parts of the alimentary canal tend to vary from 1 to 4 per cent, about one-third of the maximum, in *Oxyurias vermicularis*. The location of the vulva probably varies at least 15 per cent in a long series of individuals. The location of the anus varies over 7 per cent, or about one-third of the length of the tail. Variations in width are so great that some individuals are over twice as wide as others. The length of the body of some individuals is one-third greater than that of others. The use of the formula is likely to yield more confusion than assistance. It is impossible to indicate the observed range, and without that the numbers are meaningless. Carrying the measurement to 0.1 per cent gives an appearance of accuracy which does not exist. The formula is likely to result in the multiplication of so-called species without a proper basis for their separation.

"A species should not be described as new on account of a deviation from the proportions of known species unless that deviation is great and fundamental. The space occupied by the reproductive organs should not be considered, and little dependence should be placed on the width of the body. From four to ten individuals should always be studied and the observed range recorded. In this way the varying proportions of the different species can be used in the identification of collected specimens. An individual should never be identified, however, on the basis of the formula alone or of the proportions alone."

FOODS—HUMAN NUTRITION.

Contribution to the knowledge of the ripening of meat, H. KREN (*Wiener Tierärztl. Monatsschr.*, 1 (1914), No. 12, pp. 585-589).—Analytical data are reported regarding samples of meat kept in cold storage from 1 to 8 days. The results indicate, in the author's opinion, that the ripening of meat depends upon the hydrolytic cleavage of the protein.

Studies on the digestibility of milk and means of increasing it, L. GAUCHER (*Bul. Gén. Théor. Méd. et Chirurg.*, 167 (1914), No. 14, pp. 371-381; *abs. in Zentbl. Biochem. u. Biophys.*, 17 (1914), No. 1-2, pp. 29, 30).—In the opinion of the author the difficulty experienced by individuals in digesting cows' milk is due to the coagulation of the casein in the stomach in large masses rather than in finely divided particles. He recommends that antirennet of calf or horse serum be added to the milk to secure the formation of a finely divided curd in the stomach, as the casein in this condition passes readily into the intestines for digestion.

The influence of milk feeding on mortality and growth, and on the character of the intestinal flora, L. F. RETTGER (*Jour. Expt. Med.*, 21 (1915), No. 4, pp. 365-388).—This paper reports a large number of feeding experiments with laboratory animals (chicks and rats), some of which have been previously noted (*E. S. R.*, 33, p. 273).

No difference was observed in the relative value of ordinary sour milk and of the so-called bulgaricus product. The milk and lactose diet exerted a great influence upon the character of the intestinal bacteria in the case of both white rats and chicks which is attributed to the lactose contained in the milk, as other carbohydrates than lactose failed to exert this influence.

"The ingestion of foreign bacteria, even in large numbers, does not of itself bring about an elimination or displacement of the common intestinal microorganisms. Vastly more important is the influence of diet, especially milk and lactose. The feeding of Bulgara tablets or other preparations which contain as the supposedly active agent the bacillus of Metchnikoff and Mazé, without due regard to the use of milk, can, therefore, be of little, if indeed of any, value. The beneficial effects which it is claimed have been derived from the use of yoghurt, and other oriental sour milk products have in all probability been due to the milk as such, rather than to the bacteria which they contained."

The germicidal effect of lactic acid in milk, P. G. HEINEMANN (*Jour. Infect. Diseases*, 16 (1915), No. 3, pp. 479-486).—In the experiments here reported samples of sterile milk containing different concentrations of lactic acid were inoculated with *Bacillus coli*, *B. dysenteriae*, *B. typhosus*, and *B. paratyphosus B*, and incubated. Bacteriological examinations of these samples were then made to determine the growth of the organisms.

From the results of these experiments the author concludes that, although resistant strains may survive, the growth of pathogenic bacteria in milk is unlikely in the presence of 0.6 per cent of lactic acid. "The smaller the initial amount of lactic acid, the more likely is the growth of acid-tolerant strains.

Consequently, the slower milk sours, the greater is the danger of pathogenic bacteria surviving."

The use of saccharose and invert sugar in the preparation of bread, J. JELFNEK (*Ztschr. Zuckcrindus. Böhmen*, 39 (1915), No. 7, pp. 281-283).—In this series of baking tests it was found that from 5 to 6.25 per cent of sugar may be satisfactorily incorporated in the dough for bread making, and that invert sugar may be used to as good advantage as cane sugar.

Wild plants used as food, K. KRAUSE (*Mitt. Deut. Landw. Gesell.*, 30 (1915), No. 21, pp. 315-319).—A number of species of plants used for greens, salad, and other table purposes are described.

Jams, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 309* (1915), pp. 33).—This bulletin reports the results of the analyses of 227 samples of jams purchased in various provinces of Canada. A discussion of the general character and adulteration of the samples is included.

Baking powders, A. MCGILL (*Lab. Inland Rev. Dept. Canada Bul. 308* (1915), pp. 33).—This bulletin contains the results of chemical analyses of 251 samples of baking powders purchased in various parts of Canada during the last three months of the year 1914. These results would indicate that cream of tartar baking powders are gradually being replaced by powders made with dried alum and calcium acid phosphate.

[Food inspection and analysis], E. F. LADD and ALMA K. JOHNSON (*North Dakota Sta. Spec. Bul.*, 3 (1915), No. 18, pp. 305-320).—General information regarding pure food topics is given, together with specific information regarding a number of samples of different foods analyzed.

The electric cooking problem, R. E. FRICKEY (*Jour. Electricity*, 34 (1915), No. 23, pp. 475-478, figs. 4).—In this article is described a thermal storage cooker, the essential parts of which consist of a heat chamber, containing cast-iron radiators surrounded by the heating element, and above this a cooking chamber. Both chambers are surrounded by a heat insulating medium and a water jacket, suitably insulated, which acts as a hot-water reservoir. This reservoir is provided with an immersion water heater arranged for use as desired. Cost data are given for the preparation of standard daily menus, and compared with the results of a similar test with an ordinary range.

Electric cooking, mainly from the consumer's point of view, W. R. COOPER (*Inst. Elect. Engin. Jour.*, 53 (1915), No. 245, pp. 473-497; *rev. in Elect. World*, 65 (1915), No. 14, pp. 842, 843).—The author, an electrical engineer, reports in detail the results of experience with electric cooking in his own home. Descriptions of the apparatus, recommendations as to improvements, and cost data are given. It is stated that the cost of electric cooking was about one-third greater than in years when coal was used. The paper is followed by a discussion.

Electric cooking and heating in private houses, W. A. GILLOTT (*Jour. Inst. Elect. Engin.* [London], 53 (1914), No. 237, pp. 42-53; *abs. in Sci. Abs., Sect. B—Elect. Engin.*, 18 (1915), No. 205, I, pp. 15, 16).—Different types of apparatus are described and cost data and general information are given regarding each. The paper is followed by a discussion.

Retail prices, 1907 to December, 1914 (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 156* (1915), pp. 397).—This bulletin, which is Publication No. 14 of the Retail Prices and Cost of Living Series, consists of a compilation of statistical data regarding the relative prices of 15 articles of food in a number of different cities, for the years from 1907 to 1914, inclusive. Data are also given regarding bread weights and the prices of coal and gas for household use. A part of this data has been noted from another source (*E. S. R.*, 31, p. 558).

Roman cooks, CORNELIA G. HARCUM (*Dissertation, Johns Hopkins Univ., 1913, pp. 84*).—Much interesting information is given regarding cooks and cooking during the early history of Rome. A bibliography is appended.

The food supply of the Germans during the war, edited by P. ELTZBACHER (*Die Deutsche Volksernährung und der Englische Aushungerungsplan. Brunswick: F. Vieweg & Son, 1914, pp. VII+196; rev. in Lancet [London], 1915, I, No. 8, pp. 389-399*).—This article presents statistical data regarding the total available food supply and the actual food requirements of the German people, and outlines various methods proposed for meeting these food requirements if the country should be isolated by blockade. Detailed descriptions are given of the proposed increased utilization of agricultural products and the necessary alteration in living conditions.

Soup kitchens, M. RUBNER (*Hyg. Rundschau, 25 (1915), No. 9, pp. 309-315*).—Descriptions are given of the nutritive and energy values of some dietaries commonly furnished poor people at small cost.

Nutrition and growth, L. B. MENDEL (*Jour. Amer. Med. Assoc., 64 (1915), No. 19, pp. 1539-1547, figs. 5*).—Important data, including both those resulting from the author's own experiments (*E. S. R., 32, p. 460*) and the results obtained by other investigators, are brought together in this lecture, which considers protein, carbohydrates, fats, lipoids, and accessory diet constituents ("vitamins"), as factors influencing nutrition and growth.

The "central-normal" nutrition of adults, G. OEDER (*Berlin. Klin. Wchnschr., 52 (1915), Nos. 17, pp. 433-438; 18, pp. 466-470*).—Physical measurements of 132 men and 149 women are reported, which include that of the "central-normal" body weight (the weight associated with "central-normal" nutrition, a condition said to exist when the physical measurements conform to an arithmetical mean). The author concludes that the condition of nutrition is normal provided the measured body weight equals that indicated by the average of a large number of standard values, the index of the thickness of the abdominal fat layer lies between 2.48 and 2.69 cm., and the examination reveals no abnormal features.

The influence of drinking water on the digestibility of solid substances, F. GRÖBBELS (*Hoppe-Seyler's Ztschr. Physiol. Chem., 89 (1914), No. 1-2, pp. 1-21, figs. 3; abs. in Hyg. Rundschau, 25 (1915), No. 9, p. 329*).—The following results of experiments were noted:

Pure water left the stomach more rapidly than did bread and water mixtures. Bread eaten five minutes after drinking a moderate amount of water required twice the time for leaving the stomach as did water alone. When water was taken five minutes after eating bread, the time required for it to leave the stomach was shorter than for bread eaten alone. A mixture of bread and water remained in the stomach a longer time than did bread and water taken separately.

The influence of protein intake upon the formation of uric acid, A. E. TAYLOR and W. C. ROSE (*Jour. Biol. Chem., 18 (1914), No. 3, pp. 519, 520; abs. in Zentbl. Physiol., 29 (1914), No. 12, p. 575*).—The ingestion of abnormally large amounts of protein, following a preliminary period during which the subject received a purin-free ration, produced a very considerable increase in uric acid excretion. This may be explained by an unusual production of nuclear material from the excess of amino acids, or by an exceptional cell activity.

The creatinin excretion remained approximately constant.

The metabolism of organic and inorganic compounds of phosphorus, E. B. FORBES ET AL. (*Ohio Sta. Tech. Bul. 6 (1914), pp. 80, pls. 13*).—This bulletin reports in detail the results of a series of feeding experiments with pigs, to compare the nutritive value of representative phosphorus compounds, including

phosphates, hypophosphites, nucleic acid, phytin, and glycerophosphates. The pigs were given a basal ration low in phosphorus, consisting of pearl hominy, blood albumin, wheat gluten, and salt, to which were added the phosphorus compounds studied. In some experiments corn bran and small amounts of other substances were added to the ration to relieve feeding difficulties.

Detailed tabulated data are given regarding the gain in weight of the animals in relation to food consumed; the weight and composition of various tissues and organs of the slaughtered animals; the development and strength of the bones; the chemical balance of mineral elements; the digestibility coefficients of the proximate food constituents; and the determination of nitrogen, ammonia, and creatinin in the urine.

In the discussion of the results of these experiments the authors bring out the following facts: The results of one series of experiments indicated that "phosphorus from orthophosphates, hypophosphites, and yeast nucleic acid, when added in the pure form to rations low in phosphorus but capable of maintaining phosphorus equilibrium, may all be absorbed by swine, and may be retained in considerable quantity for at least 10 days", and although not proved, it seems possible that this retention may be permanent. Analyses of slaughtered animals showed that the mineral constituents and ether extract of the blood, as well as the relative proportions of the bone salts, varied consistently as affected by the food.

There was no evidence for the belief that phosphates and glycerophosphates have different effects upon the gross composition, growth, and metabolism of the animals. Glycerophosphates, however, are much better tolerated than are phosphates. These experiments show that "with a low-phosphorus ration it seems to be impossible to make up the deficiency of phosphorus by the addition of readily soluble phosphates in the pure form."

The phosphorus compounds studied are rated in the order of their decreasing acceptability to swine when in amounts supplying equal quantities of phosphorus as follows: Glycerophosphates, phosphates, phytin, nucleic acid, and hypophosphites.

From difficulties encountered in feeding yeast nucleic acid, commercial phytin, and the related compounds of wheat bran, the authors conclude that the isolation of such compounds changes their therapeutic effects so that it is impossible to determine from the experimental feeding of the pure compounds what is the nutritive value of these substances as they occur naturally in foods.

These experiments do not show that the organic phosphorus compounds studied (nucleic acid, phytin, and glycerophosphates) are superior to the inorganic compounds (orthophosphates and hypophosphites) as regards nutritive value. "It would seem, therefore, that for purposes of growth, the usual diet of animals must contain a sufficiently large proportion of organic to inorganic phosphorus. In this relation, then the important consideration is simply one of the total phosphorus of the ration, and any such supplemental phosphorus as is to be added to the diet of the healthy, growing animal may be added as inorganic phosphate.

"It seems unlikely that, with grown or growing animals, any ration composed from natural foods, and supplying the nitrogen requirement, will fail to furnish enough total phosphorus to maintain phosphorus equilibrium. That many rations compounded from common foods are lacking in the amount of phosphorus essential to maximum retention and growth, however, is as certainly true." . . .

"The addition of comparatively small amounts of corn to rations compounded from simple manufactured products of plant and animal origin may enhance the nutritive value of such rations to an extent out of proportion to the amount of

corn added, the particular constituent of the corn responsible for the improvement being as yet unknown, but quite possibly a vitamin."

In explanation of the low calcium content of the rations fed, the authors state that "it appears to be impossible to add to a ration low in phosphorus any considerable amount of calcium carbonate without causing profound digestion disturbance. . . . No such result follows the administration of calcium carbonate in a ration of natural foods having normal phosphorus content."

The organic phosphorus compounds of wheat bran, C. J. ROBINSON and J. H. MUELLER (*Biochem. Bul.*, 4 (1915), No. 13, pp. 100-117).—A controversial article. Analytical data are reported, the results of which are in disagreement with the work of Anderson (*E. S. R.*, 33, p. 11).

The maize feeding of normal individuals and pellagrins, P. ALBERTONI and P. TULLIO (*Arch. Ital. Biol.*, 62 (1914), No. 3, pp. 305-325).—From data derived from a number of physiological experiments in which was studied the effect of consuming a diet consisting of maize alone and of maize to which was added protein from other sources, the authors conclude that pellagra is a "deficiency disease" produced by subsisting on a diet deficient in animal protein.

The action of caffein substances, G. VINCI (*Arch. Ital. Biol.*, 61 (1914), No. 3, pp. 401-439; *abs. in Zentbl. Physiol.*, 30 (1915), No. 1, pp. 28, 29).—Following a series of experiments in which various quantities of caffein were administered to dogs, it is concluded that as much as 10 mg. of caffein per kilogram of body weight (which the author states is much greater than the amount ordinarily ingested by drinking coffee) is without injurious action on the kidneys.

The rational apportionment of the dietary during the 24-hour cycle, BERGONIE (*Rev. Sci. [Paris]*, 53 (1915), 1, No. 9, pp. 138-145, figs. 4).—A summary and digest of data, including a number of curves showing the distribution of the heat production during the 24-hour cycle. The relative advantages of eating two and three meals a day at different times are considered by comparing the amount and distribution of energy furnished in each case with the amount of energy required by the body throughout the day.

Studies on tissues of fasting animals, S. MORGULIS, P. E. HOWE, and P. B. HAWK (*Biol. Bul. Mar. Biol. Lab. Woods Hole*, 28 (1915), No. 6, pp. 397-406, pl. 1).—Detailed descriptions are given of the changes occurring in the structure of the tissues of fasting animals, as shown by a histological study of several laboratory animals which had died of protracted inanition. A short bibliography is included.

Muscular work and the respiratory quotient, S. MORGULIS (*Biochem. Bul.*, 3 (1914), No. 11-12, pp. 435-439).—The author observes that the value for the respiratory quotient during muscular work, as frequently determined by others, is extremely high, and suggests that this is due to incomplete removal of water vapor from the ventilating air current by the sulphuric acid absorbers, a part of the water thus being weighed as CO₂. He supports the hypothesis of Zuntz that all food materials are sources of energy for muscular work.

The energy metabolism of infants in relation to age and nutritive condition, J. R. MURLIN (*Proc. Soc. Expt. Biol. and Med.*, 12 (1914), No. 1, pp. 15, 16; *abs. in Zentbl. Physiol.*, 29 (1914), No. 12, p. 567).—Determinations are recorded of the energy metabolism of children up to 1 year of age. The average value for newly born children, during sleep, was found to be 1.87 calories per hour per kilogram of body weight; 2.38 calories for those of 2 to 4 months; and 2.45 calories for those 6 to 12 months old. Related to the area of body surface, the energy metabolism for the infants of the three different ages was 25, 35, and 42 calories per hour. For poorly nourished children and those under weight

the heat output was somewhat greater, and for heavy infants a little less than the average metabolism of $2\frac{1}{2}$ calories per hour per kilogram of body weight.

ANIMAL PRODUCTION.

Nutrition with purified food substances, E. V. McCOLLUM and MARGUERITE DAVIS (*Jour. Biol. Chem.*, 20 (1915), No. 4, pp. 641-658, figs. 9).—In continuation of previous work (E. S. R., 32, p. 360), the authors report results of additional feeding experiments.

Laboratory animals (rats) were maintained upon a basal ration of pure casein, dextrin, lactose, agar-agar, and chemically pure salt, to which were added different food materials. The basal diet was incomplete, the rats showing normal growth for a period of about 6 months and then rapidly losing weight. The addition of olive oil to the basal ration did not prolong the growth period, as did the addition of butter fat or the ether extract of cod testicle or pig kidney. When maintained upon a diet to which butter had been added, rats gave birth to young, some of which were maintained for a long period of time on the same diet as the mother. The results of feeding experiments by Osborne and Mendel (E. S. R., 31, p. 560) are discussed in relation to the results obtained by the authors.

The influence of certain vegetable fats on growth, E. V. McCOLLUM and MARGUERITE DAVIS (*Jour. Biol. Chem.*, 21 (1915), No. 1, pp. 179-182, pls. 9).—In continuation of the work reviewed above, experiments are reported in which laboratory animals (rats) were maintained upon a fat-free diet of casein, milk sugar, dextrin, agar-agar, and pure salt until a loss of weight and enfeebled condition of the animals resulted. Fifty per cent of this fat-free diet was then replaced by various vegetable substances containing fat, such as corn, wheat embryo, rye, and rolled oats, and in some experiments by dried pig heart and kidney.

When the corn or wheat embryo was added to the diet the animals showed an increase in weight and a normal appearance. Less favorable results were obtained by the addition of the same amount of the entire wheat kernel, rye, or rolled oats to the diet.

The results of these experiments showed that "50 per cent of corn added to the fat-free diet is vastly superior to 5 per cent butter fat when the animals have been brought to a point near which failure of nutrition would set in. The addition of 5 per cent wheat or 5 per cent corn meal is not sufficient to prevent decline and death on the fat-free diet."

The authors state that "the effects of wheat, rye, and oats seem to suggest that the differences observed in their effects on depleted animals may well be due to quantitative differences in the yield of the unknown accessory substances under consideration rather than to an entire absence of the same. This viewpoint is strongly supported in the case of the wheat kernel as compared with wheat embryo."

The value of the proteins of the cereal grains and of milk for growth in the pig, and the influence of the plane of protein intake on growth, E. V. McCOLLUM (*Jour. Biol. Chem.*, 19 (1914), No. 3, pp. 323-333).—In metabolism experiments with young pigs fed on rations made up of purified feedstuffs, the principal sources of protein being oats, wheat, corn, wheat gluten, casein, and skim milk, supplied at different planes, it was found that "with moderately low protein intake (6.6 to 10 per cent) the rate of nitrogen retention is influenced by the amount of food protein in proportion to the metabolizing tissues of the body and apparently in some degree by the excess of total energy consumed over the maintenance needs of the animal. When the energy supply is

generous (100 calories per kilogram or more) the rate of nitrogen retention as expressed in percentage of ingested nitrogen is not much influenced by the plane of protein intake at levels above 10 per cent of the ration. In experiments in which the protein amounted to 41 to 57.86 per cent of the ration the maximum possible percentage of the ingested nitrogen continues to be retained for growth." It is concluded that "in the young pig the growth impulse is so great that the synthesis of body protein is effected at the maximum rate possible with the particular mixture of amino acids yielded by the food proteins."

Figures are given for the percentage of the absorbed nitrogen retained for new growth and indicate the degree to which the amino acids of the food can be recombined into tissue proteins. There was little difference in the value for growth of the protein mixture contained in the three cereal grains, wheat, oats, and corn kernels. A maximum of from 23 to 24 per cent of the ingested nitrogen from one of these sources apparently can be retained for growth.

It is further concluded that "the rate of retention of nitrogen, in all cases where a sufficiently high plane of protein intake was fed, was limited by the chemical make-up of the food proteins, and not by the physiological capacity of the animals to grow."

While these experiments were of short duration, it was observed that toward the close of the experiment there was a tendency for the rate of nitrogen retention to fall slightly, indicating that in a long-continued experiment on a single grain ration a steady decline in the rate of growth ultimately sets in.

See also previous notes (E. S. R., 29, p. 64; 33, p. 367).

The nutritive value of old and new corn, J. J. NIZESCO (*Compt. Rend. Soc. Biol. [Paris]*, 77 (1914), No. 33, pp. 583-586).—In experiments with chickens and rats it was found that new corn was less completely digested than old corn, and that greater gains in live weight were obtained when old corn was fed.

A study of grazing conditions in the Wenaha National Forest, H. T. DABLINGTON (*Washington Sta. Bul.* 122 (1915), pp. 3-18, pls. 7).—The purpose of this study was to determine the character and carrying capacity of the grazing areas contained in the Wenaha National Forest, situated in the southeastern part of Washington and the northeastern part of Oregon.

It was found that the principal forage plants of the higher portions are perennial in character, consisting principally of shrubs. There appears to have been no appreciable deterioration in the grazing areas. On account of snow, the range is limited to about five months' grazing, a fact which will insure permanency of the grazing area. The full carrying capacity of the range is not being utilized. It is said that so far as the regulation of the sheep industry and the enforcement of law and order are concerned, government leasing to single individuals has been a marked success in the Wenaha National Forest. A bibliography on range management and improvement is appended.

Chemical analyses of forage plants of Spain, R. SUÁREZ Y BERMÚDEZ (*Análisis Químico de las Plantas Esteparias de España. Madrid: Langa y Compañía, 1912, pp. 94*).—Analyses are given of *Brachypodium pinnatum*, *Phragmites gigantea*, *Bromus rubens*, *Aphyllantes monspeliensis*, *Crocus sativus*, *Urtica urens*, *Arthrocnemum macrostachyum*, *Chenopodium album*, *Salsola vermiculata*, *Atriplex halimus*, *A. rosca*, *Kochia prostrata*, *Amaranthus albus*, *Rameria hybrida*, *Glaucium corniculatum*, *Moricandia arvensis*, *Carriehtera velle*, *Malcomia africana*, *Biscutella laevigata*, *Conringia orientalis*, *Anthyllis cytisoides*, *Ononis tridentata*, *O. viscosa*, *Hedysarum humile*, *Onobrychis saxatilis*, *O. eriophora*, *Coronilla minima*, *Lupinus angustifolius*, *Vicia cracca*, *Zygophyllum tobago*, *Tribulus terrestris*, *Lithospermum fruticosum*, *Teucrium chamæpitys*, *Crucianella maritima*, *Xanthium strumarium*, *Silybum marianum*, *Andryala ragusina*, *Sonchus crassifolius*, *Artemisia herba-alba*, and *A. glutinosa*.

The influence of temperature on the microflora of hay: Lactic and butyric hays, C. GORINI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5 ser., 23 (1914), I, No. 12, pp. 984-988; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 12, pp. 1626, 1627).—In a zymoscopic and bacteriological examination made of hay during its various stages of fermentation, it was found that during the first three to five days the fermentation with a temperature of 50 to 55° C. (122 to 131° F.) was prevailinglly lactic, while as the temperature gradually rose to 60 to 65° and beyond, the mass tended to become more of the butyric type, which renders it less desirable for feeding purposes. Lactic acid fermented hay may be obtained by expelling as much air as possible and maintaining a temperature of about 50°.

Sugar as a feeding stuff, NEUBAUER (*Landw. Ztschr. Rheinprovinz*, 16 (1915), No. 12; pp. 197-200).—A general review of experiments in feeding sugar to horses, cattle, and swine, in which it has proved to be a desirable feed.

The value of dried brewers' grains as a feeding material, E. T. HALNAN (*Jour. Bd. Agr. [London]*, 21 (1914), No. 9, pp. 821-825).—A résumé of the results obtained by various investigators on the feeding value of dried brewers' grains, previously reported from other sources.

Dried yeast as food for farm stock, C. CROWTHER (*Jour. Bd. Agr. [London]*, 22 (1915), No. 1, pp. 1-10).—Dried yeast is described as a material of powdery to flaky consistency, varying in color from light to medium brown. It has an agreeable smell, but a rather bitter taste, arising presumably from the presence of hop residues with which the yeast is contaminated, which is disliked by cows but is not objected to by pigs and calves. The average composition is given as moisture 4.3 per cent, protein 48.5, fat 0.5, soluble carbohydrates 35.5, fiber 0.5, and ash 10.7.

From feeding trials at Garforth, it appears that dried yeast is a desirable feed for cows if they can be induced to eat it, but it is thought that until some means of depriving it of its bitter taste has been devised dried yeast will never come into general use as feed for cows. In trials with 12-weeks-old pigs fed 15 weeks, dried yeast proved to be a good feed, giving better results than those obtained with an equal weight of middlings. It proved to be a safe feed for calves, although no tests were made of its comparative feeding value.

It is said that dried yeast keeps well and on mixing with other meals and water may be kept for some time without objectionable fermentation. It is not thought that it possesses any special medicinal or dietetic virtues other than those to be expected in any highly digestible feed rich in protein.

Ensiling feed materials with the aid of a lactic acid bacteria culture, B. HEINZE (*Jahresber. Ver. Angew. Bot.*, 11 (1913), No. 2, pp. 142-167).—This is a résumé of information on methods of inoculating silage with a lactic acid bacteria culture.

Studies on the preparation of silage, F. SAMARANI (*Bol. Min. Agr., Indus. e Com. [Rome], Scr. C*, 12 (1913), No. 8-12, pp. 87-103; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 5 (1914), No. 12, pp. 1625, 1626).—In reviewing his experiments in making silage, the author states that acetic and lactic fermentations take place. The first is an intracellular process through which the sugars of the cell substance are transformed in the almost complete absence of oxygen, first into alcohol and carbonic acid, and later by chemical action into acetic acid. The second process is an ordinary lactic acid fermentation, due to bacterial action. Of the total free acid content of normal silage, 70 per cent is acetic acid, 20 per cent lactic acid, and about 10 per cent butyric acid.

In order to make the best silage it is necessary to avoid overheating the fodder in order to limit the acetic fermentation and thus to leave the decomposition of the sugar chiefly to the lactic fermentation process. Lactic fermentation may be promoted by the addition to the silage of a solution of milk sugar. In experiments with mechanical pressure applied immediately after the required amount of fodder has been put in, it has been found possible to exclude the air, lower the temperature, and thus promote lactic fermentation at the expense of the acetic fermentation. Where mechanical pressure is applied, the silage contains less free acid and consequently smells less strongly.

In ensiling beet slices it was found necessary to remove all the air from the silo, which was best effected by means of heavy pressure.

Silage and grains for steers, J. W. WILSON (*South Dakota Sta. Bul. 160 (1915), pp. 197-223, figs. 10*).—The object of these experiments was to determine the relative value of sorghum silage and corn silage, both with and without oil meal for the preliminary gain; the value of feeding the leguminous hays with silage for the preliminary gain; the relative feeding value of the commonly grown grains with corn silage as the sole roughage ration for fattening cattle; and to show how these big cheap gains with silage during the preliminary period could be maintained after the steers were put on a full feed of grain.

Five lots of four grade Hereford steers each, weighing approximately 675 lbs. each, were fed during a preliminary period of 55 days as follows: Lot 1, 37 lbs. of corn silage per head per day; lot 2, 48 lbs. of corn silage and 2.9 lbs. of oil meal; lot 3, 42 lbs. of corn silage and 3.8 lbs. of oil meal; lot 4, 40 lbs. of sorghum silage; lot 5, 47 lbs. of sorghum silage and 2.9 lbs. of oil meal. They made average daily gains per head of 1.55, 3.36, 3.12, 0.74, and 1.85 lbs., costing 3.7, 3.55, 4.27, 8.14, and 6.64 cts. per pound of gain for the respective lots.

These steers were redivided and five lots of four steers each were fed during a 115-day fattening period as follows: Lot 1, 11 lbs. of corn silage, 18 lbs. of ground corn, and 1.8 lbs. of oil meal per head per day; lot 2, 41 lbs. of corn silage and 3 lbs. of oil meal; lot 3, 11 lbs. of corn silage, 15 lbs. of ground oats, and 1.5 lbs. of oil meal; lot 4, 11 lbs. of corn silage, 13 lbs. of barley, and 1.3 lbs. of oil meal; lot 5, 11 lbs. of corn silage, 17.6 lbs. of spelt, and 1.8 lbs. of oil meal. These steers made an average daily gain per head of 2.13, 1.46, 2.19, 1.9, and 2.17 lbs. for the respective lots.

In a second experiment five lots of four grade Aberdeen Angus steers each, weighing approximately 775 lbs. each, were fed during a preliminary period of 91 days as follows: Lot 1, 59 lbs. of corn silage and 2 lbs. of red clover hay per head per day; lot 2, corn silage ad libitum (an average of about 62 lbs. per head per day); lot 3, 58 lbs. of corn silage and 3.84 lbs. of sweet clover hay; lot 4, 58 lbs. of corn silage and 16 lbs. of alfalfa hay; and lot 5, 58 lbs. of corn silage and 12 lbs. of prairie hay. These steers made an average daily gain per head of 2.29, 2.32, 2.45, 2.49, and 2.01 lbs., costing 4.55, 4.03, 4.34, 4.3, and 4.79 cts. per pound of gain for the respective lots. These same lots were then fed during a 101-day fattening period as follows: Lot 1, 17.4 lbs. of corn silage, 15.7 lbs. of ground corn, and 1.5 lbs. of oil meal per head per day; lot 2, 56 lbs. of corn silage and 2.93 lbs. of oil meal; lot 3, 17 lbs. of corn silage, 15 lbs. of ground oats, and 1.5 lbs. of oil meal; lot 4, 17.4 lbs. of corn silage and 16.5 lbs. of barley; lot 5, 17 lbs. of corn silage, 16 lbs. of ground spelt, and 1.7 lbs. of oil meal. These steers made average daily gains of 2.26, 2.24, 1.78, 2.28, and 2.24 lbs., costing 9.37, 6.1, 11.65, 9.65, and 9.47 cts. per pound of gain. For the entire 192 days' feeding period, the costs were 7.2, 5.1, 7.6, 7, and 7.38 cts. per pound of gain for the respective lots.

It is concluded that a preliminary feeding period is one of the best methods to follow in fattening cattle for market. Corn silage was preferable to sorghum silage. The addition of 3 lbs. of oil meal to both the sorghum and corn silage rations increased the gains and reduced the cost of production. The large gains secured during the preliminary period were maintained during the fattening period. The addition of leguminous hays to the silage ration increased the gains but did not reduce the cost. Alfalfa hay was found the best of the legumes to feed with corn silage for a large gain. Corn silage as the sole roughage with the grains during the fattening period proved to be a suitable substitute for hay. Prairie hay did not prove to be of as much value when fed with corn silage during the preliminary period, in producing a large gain, as did the hays made from the legumes. Sweet clover, when made into hay before the stems became too woody and the hay run through a cutter, proved to be nearly as valuable for feeding with corn silage during the preliminary period as alfalfa hay.

Analyses are given of wild hay, alfalfa hay, corn silage, clover hay, and sweet clover hay.

The use of mineral phosphates in calf rearing, A. H. FAIRBAIRN and C. HUTCHINSON (*Jour. Southeast. Agr. Col. Wye, No. 22 (1913), pp. 170-174*).—Calves receiving the addition of a mineral phosphate gave no marked increase in the rate of progress as compared with calves receiving an ordinary ration.

Estimating the age of calves, J. SCHWARZ (*Ztschr. Tiermed., 18 (1915), No. 11-12, pp. 476-502, figs. 8*).—The author concludes from his studies of the appearance of the calf's hoof during the first few weeks after birth that the character of the sole cushion is not indicative of the age of the calf, but that the rings of the horny wall are indicative of the age. A calf having the first hoof ring is between 5 and 14 days old; the second hoof ring, between 4 and 5 weeks old.

The estimation of condition in cattle, J. A. MURRAY (*Reading, Pa.: Charles Elsbury, 1914, pp. 11*).—The author is of the opinion that the terms used by farmers to denote the "condition" of cattle are vague and indefinite, and that some more exact method is needed. A formula is arrived at by which the condition may be found from the live weight, girth, and length.

Origin of cattle, G. LAURER (*Deut. Landw. Tierzucht., 18 (1914), Ausgabe A, Nos. 48, pp. 513-516; 49, pp. 521-523, figs. 4*).—This is a contribution on the origin and development of our modern breeds of cattle.

The cattle of Brazil, J. MARIA DOS REIS (*Jour. Heredity, 6 (1915), No. 5, pp. 203-211, figs. 4*).—The author describes the native stock of Brazil as among the finest in the world, but ruined by indiscriminate cross-breeding. It is stated that the introduction of the zebu is jeopardizing the live-stock industry, as the hybrids are generally wild and degenerate, poor milkers, and unable to raise their own offspring.

Zebu cattle in Brazil, B. H. HUNNICUTT (*Jour. Heredity, 6 (1915), No. 5, pp. 195-201, pl. 1, figs. 4*).—An account of the introduction and development of the zebu in Brazil. The crosses on the native stock are described as being popular with ranchers, hardy, disease-resistant, and fairly good milkers.

Zebu crosses in Tunisia, M. ROEDERER (*Jour. Heredity, 6 (1915), No. 5, pp. 201, 202*).—Zebu crosses with Arab cattle are described as being of good size, good butcher quality, easily kept in condition, hardy, and excellent as draft animals. The Asiatic race of zebu is preferred for crossing purposes.

Measurement of the Formosan buffalo, H. YANAGAWA (*Trans. Sapporo Nat. Hist. Soc., 5 (1915), No. 3, pp. 143-145*).—Measurements are given of the Formosan buffalo, which is described as being similar to the carabao or water buffalo of the Philippine Islands.

Seventh annual report of the American Bison Society (*Ann. Rpt. Amer. Bison Soc.*, 7 (1914), pp. 72, figs. 23).—It is said that there has been an increase of 546, or 19 per cent, in the number of buffaloes in North America within the past year, and that owing to the increased interest in this animal its preservation is assured. See also a previous note (E. S. R., 30, p. 469).

Practical assistance to wool growers in the marketing of their wool clips (*Canada Dept. Agr., Live Stock Branch Pamphlet 7* (1914), pp. 18).—General information on the production of wool of good quality and condition, together with suggested plans for use in organizing a wool growers' association, is presented.

The Grenada goat, L. GIMENEZ (*Indus. Pecuaría*, 15 (1914), No. 462, pp. 377, 378, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discusst.*, 6 (1915), No. 1, p. 116).—This breed of goats is described as being hornless and of average size. The color is chestnut or black, and the udder is large and well developed. The she-goats become serviceable at 6 months and may continue to breed to the age of 9 or 10 years. They mostly give birth to twins and sometimes triplets. The yield of milk is generally from 2.6 to 3.5 lbs. per day after the first parturition, the quantity increasing with subsequent lactations until the fifth, when it reaches its maximum of from 13.2 to 14.1 lbs. The milk is said to be excellent and without the characteristic odor of that of other breeds of goats. The flesh is also of good quality.

[Pork production], M. HERTER and G. WILSDORF (*Arb. Deut. Landw. Gesell.*, No. 270 (1914), pp. 1-38, figs. 15).—A discussion of the comparative value of the Berkshire, Yorkshire, and native German breeds of hogs for pork production, and of the methods of swine feeding.

Swine feeding experiment comparing skim milk with fat-freed fish meal and dried yeast, KLEIN (*Milchw. Zentbl.*, 43 (1914), No. 17, pp. 452-458).—In experiments with young pigs fed a basal ration of potato flakes and barley, it was found that $\frac{1}{2}$ lb. of fat-freed fish meal or 1 lb. of yeast was equivalent for feeding purposes to 1 gal. of skimmed milk. These feeds, especially the yeast, gave better results with older than with younger pigs.

The valuation of the manurial residues obtained from the consumption of foods by growing pigs, C. CROWTHER and A. G. RUSTON (*Jour. Bd. Agr. [London]*, 21 (1914), No. 9, pp. 789-800).—With a view to determining the manurial value of pig offal, ten 2-month-old Yorkshire pigs were fed for 23 weeks on rations composed of bran, middlings, pea meal, and barley meal, and collections and analyses made of the urine and feces. The percentage of the food nitrogen recovered ranged from 44 in the earlier stages to 68 in the later stages, with an average of 56; phosphoric acid, 45 to 71 with an average of 58; potash from 67 to 98 with an average of 87; and lime from 30 to 75 with an average of 65. The distribution of the manurial ingredients recovered between solid and liquid excreta was found to be as follows: Nitrogen 35 per cent in the solid, 75 per cent in the liquid; phosphoric acid 77 and 23; potash 18 and 82; and lime 92 and 8, respectively. These values are lower than those given by Voelcker and Hall (E. S. R., 14, p. 1057).

Sex-linked factors in the inheritance of rudimentary mammae in swine, E. N. WENTWORTH (*Proc. Iowa Acad. Sci.*, 21 (1914), pp. 265-268).—The author presents evidence tending to show that the inheritance of rudimentary mammae in swine is a combination of the sex-linked and sex-limited types. It appears sex-linked in so far as the transmission of the genetic factor for rudimentaries is concerned, and sex-limited in so far as there is apparent repression somatically of the rudimentaries of the female sex when they are in a simplex condition.

Polygamous Mendelian factors, J. WILSON (*Sci. Proc. Roy. Dublin Soc., n. ser., 14 (1914), No. 22, pp. 302-312*).—Data are presented which tend to show that the various colors in horses are the result of single polygamous factors.

Annual report on the administration of the grant for the encouragement and improvement of the light horse-breeding industry for the year 1913-14 (*Bd. Agr. and Fisheries [London], Ann. Rpt. Light Horse-Breeding Indus., 1913-14, pp. 56*).—This outlines the general plan for the encouragement and improvement of light horse breeding in England, which consists in the subsidizing of stallions to travel at low fees, the providing of brood mares for farmers at a small rental, and the elimination of unsound stallions.

Growth of the horse, R. MOTLOCH (*Deut. Landw. Tierzucht., 18 (1914), Ausgabe A., Nos. 50, pp. 529-532; 51, pp. 537, 538, figs. 3*).—This is a contribution on the growth and body development of the horse from birth to five years of age.

Feeding roots to work horses, N. HANSSON (*Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 98 (1914), pp. 16, figs. 2*).—Successful experiments are reported in which an average of 13.5 kg. of sugar beets per head per day was fed to work horses for from 50 to 89 days with a resulting average daily gain of 0.03 kg. per head. Horses receiving 1.5 kg. of grain mixture per head per day under the same conditions lost 0.07 kg. in weight.

Mendelian inheritance of fecundity in the domestic fowl, and average flock production, R. PEARL (*Amer. Nat., 49 (1915), No. 581, pp. 306-317, fig. 1*).—The author summarizes the material presented in this paper as follows:

"There is a marked difference in average egg production per bird of Barred Plymouth Rock pullets of the Maine Station strain at the present time as compared with what obtained during the period of simple mass selection for this character. This difference is in the direction of a substantially higher mean production at the present time, when tested on flocks of large size. The increase in flock average productivity is most pronounced in respect to winter production, which is the laying cycle to which especial attention has been given in the breeding. The cause of this increase in flock productivity appears, with a degree of probability which is very high and amounts nearly to certainty, to be that the method of breeding the stock now followed is more closely in accord with the mode of inheritance of fecundity than was the simple mass selection practiced in the earlier period. The result announced in earlier papers that high fecundity is a sex-linked character, for which the female is heterozygous, has been confirmed by practical poultrymen in their breeding operations."

Previous work has been noted (E. S. R., 24, p. 675; 28, p. 576).

Xenia in fowls (*Jour. Heredity, 6 (1915), No. 5, pp. 212-218, figs. 2*).—This is a review of recent German work to determine whether a cock has any influence on the color and form of eggs laid by hens to which he is mated. The work of Walther (E. S. R., 32, p. 263) is cited to show that this theory is without solid foundation.

Studies on the physiology of reproduction in the domestic fowl.—XII, On an abnormality of the oviduct and its effect upon reproduction, MAYNIE R. CURRIS (*Biol. Bul. Mar. Biol. Lab. Woods Hole, 28 (1915), No. 3, pp. 154-162, pls. 2*).—This is a description of an abnormality of the oviduct of a year and a half old Rhode Island Red hen at the Maine Experiment Station.

Every possible stage of absorption of the egg from a normal membrane shelled fresh egg to collapsed empty membranes was found. "Some of the eggs and some of the empty membranes were free in the body cavity. Some were partly or entirely inclosed by peritoneum. In several instances two eggs or an egg and a bunch of membranes were walled off together. These peritoneal

covered masses were attached by suspending strings or folds of peritoneum. One was a normal fresh egg in a single egg membrane. Ten had evidently been normal eggs but at the time of autopsy they contained a homogeneous mixture of yolk and albumin which had lost the gelatinous character of fresh egg albumin. Each of these eggs was inclosed in a single egg membrane. The other four eggs were double eggs."

"The most probable explanation of the abnormality of the oviduct found in the case described is that in early embryonic development (probably on the sixth or seventh day of incubation) the backward growth of the primordial oviduct stopped permanently, while the differentiation of the part already formed continued in the normal manner.

"As in other cases where the passage of the egg is prevented the sex organs passed through their normal reproductive cycles; the oviduct functioned as far as the point where the passage was interrupted; the eggs were then returned to the body cavity and resorbed. The number of eggs and empty egg membranes found in this fowl, which was apparently in a perfectly normal physical condition, show that a bird possesses very great power of resorption of its own proteins from the peritoneal cavity. Such resorption does not necessarily cause metabolic disturbances."

Studies on the physiology of reproduction in the domestic fowl.—XIII, On the failure of extract of pituitary body (anterior lobe) to activate the resting ovary, R. PEARL and F. M. SURFACE (*Jour. Biol. Chem.*, 21 (1915), No. 1, pp. 95-101).—In an earlier paper (*E. S. R.*, 32, p. 671) it was shown that the substance of the corpora lutea of the cow has the power to inhibit ovulation in an actively laying fowl. The purpose of this study was to determine whether there is any chemical substance which will activate the resting ovary.

It was found that "the substance of the anterior lobe of the pituitary body of the cow, when injected into the abdominal cavity of hens in which the ovary is in a completely resting condition, does not cause an activation of the ovary, in the sense of inducing ovulation at an earlier date than that at which it would normally occur."

The cholesterol metabolism of the hen's egg during incubation, J. H. MUELLER (*Jour. Biol. Chem.*, 21 (1915), No. 1, pp. 23-28).—As a result of his studies the author concludes that "the cholesterol of the newly laid hen's egg is practically all in the free condition. During the period of incubation this condition obtains until about the thirteenth day, from which time there is a gradual esterification until, at the time of hatching, over 40 per cent of the cholesterol present is in the form of esters. The esterifying cholesterol may function as a detoxifying substance, with which the toxic fatty acids, set free from lecithin during the latter stage of embryonic development, combine to form harmless esters."

Studies on the energy metabolism of the domestic fowl, H. GERHARTZ (*Landw. Jahrb.*, 46 (1914), No. 5, pp. 797-814; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Discases*, 5 (1914), No. 12, pp. 1623, 1624).—The author reviews the work of a number of earlier investigators, and gives the results of his own studies in determining the amount of energy required daily by hens per kilogram of live weight and per 1,000 sq. cm. of body surface during the molting, laying, and resting periods.

The minimum requirement amounted to 58.37 calories per 1,000 sq. cm. of body surface per day for the normal fasting fowl; 62.15 calories for the same bird that had been fed; and 71.78 calories for the brooding hen after feeding. This is a somewhat lower requirement than that of other animals, it appearing that fowls in a state of absolute repose have a relatively low transformation of energy. During the molting period the transformation was slightly in-

creased. There was an increase in the energy transformation during the egg-laying period, from 24.8 to 26.2 calories per 1,000 sq. cm. of body surface per day being utilized in the formation of the egg.

Poultry for profit, JEAN A. KOETHEN (*Los Angeles, Cal.: Cultivator Publishing Co., 1915, pp. 229, pls. 17, figs. 17*).—A general treatise on the feeding, care, and management of poultry.

A simple trap nest for poultry, A. R. LEE (*U. S. Dept. Agr., Farmers' Bul. 682 (1915), pp. 3, figs. 2*).—Full directions are given for making a trap nest.

DAIRY FARMING—DAIRYING.

Difficulties encountered in making high-grade milk, and their practical solution, J. R. WILLIAMS (*N. Y. Dept. Agr. Bul. 68 (1915), pp. 1021-1032, pls. 4*).—The author reports experiments undertaken to determine the effects of brushing and washing the udder on the bacterial content of the surface of the teats; also to determine the value of disinfectants in the cleaning of the udders.

The results while not conclusive, suggest that "perfunctory washing loosens or frees from the epithelial layers of the teats more bacteria than it removes, so that more germs may be readily removed in the handling of the teat after the washing than before. Washing from a common pail may carry germs from one cow to another so that the process of washing instead of removing may add enormous numbers of germs to the teats. In this way cows with infected udders may be the source of infection for all other cows in the same group.

"Antiseptics apparently reduce the number of viable germs on the teats. It is uncertain, however, whether or not they are destroyed or their growth on the test plate merely inhibited.

"By far the best way to prepare a cow for milking is to wash each udder with a pail of clean water and wipe the teats with a piece of sterile cloth. It is a serious question whether or not any other method of preparation for milking is of value. Unfortunately, this method requires more labor and the extravagant use of water and sterilized cloths."

Process of sterilizing milk and cream, A. RUTTER (*English Patent 216, Jan. 3, 1914; abs. in Jour. Soc. Chem. Indus., 34 (1915), No. 9, p. 507*).—"Milk or cream is treated with from 0.05 to 0.15 per cent of its weight of an alkali peroxid, e. g., sodium peroxid, a quantity of citric acid sufficient to neutralize the alkalinity due to the peroxid is added, and the whole is then heated to 30 to 52° C. for 30 minutes or more."

The pasteurization of cream for butter making (*Iowa Sta. Bul. 156 (1914), pp. 3-40*).—This bulletin consists of two parts.

I, *Effect on quality and chemical composition*, by M. Mortensen, W. G. Gaessler, and W. H. Cooper (pp. 3-26).—In experiments conducted to determine the value of pasteurization in the manufacture of butter, the effect on the flavor of the butter, on the keeping quality, on the body, on the chemical composition, and on the mechanical losses was considered and an effort was made to determine the relative merits of the various methods of pasteurization.

Sour cream was pasteurized by the continuous and vat methods, and the continuous method using a forewarmer. Fairly satisfactory results were obtained by the continuous method of pasteurization during the summer season, but during the winter season, when the cream had to be heated from a low temperature to a high pasteurizing temperature, a metallic flavor often resulted. The amount of fat lost in the buttermilk was greater in the buttermilk obtained from pasteurized cream.

In vat pasteurization the body of the butter was somewhat inferior to that of both the raw cream butter and that from the cream pasteurized by the continuous method, in that it was not so clear and appeared a trifle sticky. The butter from pasteurized cream, either sweet or sour, scored higher on flavor, both when fresh and after storage, than from raw cream. Vat pasteurization appeared to be the most efficient method of sour-cream pasteurization for improvement of flavor, although the average fat content of the buttermilk from vat-pasteurized cream was 0.23 per cent, as against 0.115 per cent for buttermilk from cream pasteurized by the continuous method.

An effort was made to combine the two methods. The cream was heated by flash heat in a continuous pasteurizer used as a forewarmer to about 125° F., passed through a retarder, requiring about 20 minutes, and finally admitted to another continuous pasteurizer and heated to from 180 to 185°. This method was compared with the continuous method, the exposure varying from 180 to 185°. The body of the butter was practically the same with each of these two methods, and clearer and more perfect than with vat-pasteurized cream. The flavor for both fresh and stored butter produced from cream pasteurized by the vat method scored higher than that of butter produced from cream pasteurized by the continuous method after forewarming, and this in turn was higher than with continuous pasteurization without forewarming. The average fat test of the buttermilk for the cream pasteurized by the continuous method was the same with or without forewarming, and lower than for the vat-pasteurized cream. A high churning temperature resulted in a great loss of fat in the buttermilk.

An effort was made to remove undesirable odors from the butter by aerating the cream. The cream, after being treated with the blower, was a trifle more mealy than cream pasteurized by the vat method without aeration. The butter manufactured from aerated cream scored higher on flavor than that from cream not aerated. The loss of fat in the buttermilk was practically the same in both cases.

Butter manufactured from raw cream had a higher moisture content than butter manufactured from cream pasteurized by the flash method. Prolonged heating of sour cream produced a higher moisture content in the resulting butter. The percentage protein content of the resulting butter was not influenced by the pasteurization of sweet cream, but was decreased by pasteurization of sour cream.

II, *Bacteriological studies*, by B. W. Hammer (pp. 27-40).—In these studies of the bacteriological effects of pasteurization it was found that "the method of vat pasteurization of sour cream at temperatures of from 140 to 145° F. for 20 minutes sometimes left large numbers of living bacteria present, although the percentage killed was high. After pasteurizing sour cream with the flash method at from 180 to 185°, only small numbers of bacteria were found in a living condition. The use of the retarder on sour cream resulted in the destruction of a great many of the contained bacteria. From the small amount of data available, it appears, as would be expected, that the efficiency obtained approximates vat pasteurization more nearly than flash pasteurization as carried out in this work. With the use of double pasteurization on sour cream, a very high efficiency was secured and only very small numbers of organisms remained in the cream in a living condition; the results on bacterial efficiency approximate those obtained by the flash method.

"The method of blowing air through cream during the pasteurization process was found to increase the number of bacteria in the pasteurized cream in the majority of cases. Flashing sour cream at temperatures as low as 120° re-

sulted in the destruction of considerable numbers of bacteria, although the numbers remaining were very high.

"The results bear out the conclusions of various investigators that there is no exact relation between the number of living bacteria contained and the acidity of sour cream. There was no relationship between the acidity of the cream and the number of organisms remaining in the cream after pasteurization.

"Butter made from raw cream had practically as good keeping qualities as butter made from pasteurized cream. But slight differences were encountered when the deterioration of butter made from cream pasteurized by various methods was compared. The presence of foreign bacteria in cream did not cause a more rapid deterioration of the butter made therefrom."

Smith's butter fat computer, J. F. SMITH (*Picasanton, Kans.: Author, 1915, pp. 64*).—These tables are designed for the cream buyer in determining the amount and value of milk fat in cream and whole milk of various percentages and at various prices.

Experiments with cheese made from milk mixtures of different fat content, N. O. HOFMAN-BANG ET AL. (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsøg [Copenhagen], 86 (1914), pp. 5-47*).—The main objects of these experiments, which were conducted at five creameries, covering a period of four years, and 150 cheeses, were to determine the relation between the fat and the casein in both fresh and cured cheese made from milk of different fat contents, and to ascertain whether it was possible to work out a table which will show the ratio between the fat and casein in the finished cheese if the relation of these constituents is known in the milk, and vice versa. Twenty-five cheeses were made of each of the following classes: Skim milk, 15 per cent whole milk, $\frac{1}{2}$ whole, $\frac{1}{4}$ whole, and whole milk, all being from the milk from Red Danish cows. Another class consisted of cheeses made from whole milk from Jersey cows.

It is concluded that the figures expressing the relation between the fat and the casein in the finished cheese can, with fair certainty, be calculated from the percentage of fat in the milk and vice versa.

The ratio figures for whole milk, $\frac{1}{2}$ whole, $\frac{1}{4}$ whole, 15 per cent, and skim milk cheese were so different that these figures may be used in identifying the different classes of cheese. The experiments showed that in spite of variations in the figures the minimum figures for whole milk cheese were higher than the maximum figures for $\frac{1}{2}$ whole milk cheese, and the minimum figures for $\frac{1}{2}$ whole were higher than the maximum figures for $\frac{1}{4}$ whole, etc. These ratio figures are given in the following table:

Ratio figures in cheese from various milk mixtures.

	Ratio figures in cheese from milk mixtures with the following content of whole milk.					Percentage of fat in milk mixtures with the following content of whole milk.				
	100 per cent.	50 per cent.	25 per cent.	15 per cent.	0 per cent.	100 per cent.	50 per cent.	25 per cent.	15 per cent.	0 per cent.
Average of all experiments.....	128.0	65.8	34.8	21.4	3.3	3.41	1.78	0.94	0.59	0.13
Maximum.....	141.3	75.6	39.6	26.1	4.8	3.82	2.14	1.06	.69	.20
Minimum.....	107.2	55.4	27.1	16.5	2.2	2.79	1.53	.80	.50	.08

The constant, i. e., the figure which by division into the ratio figures gives the fat content of the milk mixture, is 37.3.

The pasteurizing of the milk and stirring the cheese, fine or coarse, did not disturb these ratio figures appreciably. They were also the same whether the cheese was analyzed in the fresh or cured condition and regardless of the method of storing. Attention is called to the fact that these ratio figures are purely experimental and should not be accepted as absolute standards, but can be used as guides for the choosing of such standards. The yield of cheese can be calculated in round numbers when the fat content and casein of the milk are known.

The Jersey milk gave higher ratio figures than milk from the ordinary Danish cows. These figures, however, were comparatively too low on account of the greater casein content of Jersey milk. For Jersey milk the constant 30 should be used. Jersey milk gave a greater yield of cheese than ordinary milk, due to its higher fat and casein content. The quality of cheese from Jersey milk was no different than that from Red Danish cows.

A given milk for cheese can, by the addition of skim milk, or whole milk, be so changed in its composition that a previously desired ratio between the fat and casein in the finished cheese can be assured.

VETERINARY MEDICINE.

Results of research in the general pathology and pathologic anatomy of man and animals, edited by O. LUBARSCH and R. VON OSTERTAG (*Ergeb. Allg. Path. Mensch. u. Tiere*, 17 (1915), pt. 2, pp. VII+981).—The contents of this volume include the following articles: Pathology of the Circulatory System of Animals, by H. Rievel (pp. 1-89); Pathology of the Circulatory Organs of Man, by C. Thorel (pp. 90-718); and Relations between the Liver, Bile Ducts and Infectious Diseases, by A. Posselt (pp. 719-937). To each article is appended a large bibliography.

Infection, immunity, and specific therapy, J. A. KOLMER (*Philadelphia: W. B. Saunders Co., 1915, pp. 899, pls. 31, figs. 100*).—This book has special reference to immunologic technique, but also includes some data and methods on chemotherapy. It is divided into five parts: (1) General immunologic technique; (2) principles of infection; (3) principles of immunity and special immunologic technique; (4) applied immunity in the prophylaxis, diagnosis, and treatment of disease—specific therapy; and (5) experimental infection and immunity. Part five may be used as an experimental course for the study of infection and immunity.

About the detection and significance of leucocyte-attracting substances during infection, M. BÜRGER and H. DOLD (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 21 (1914), No. 1-5, pp. 378-409*).—For studying leucotactic processes in the animal body, the knee-joint method (on the rabbit) is recommended.

Comparative investigations of the leucotactic activity of uniform sterile filtered sodium chlorid bacterial extracts, inactive bacterial serum extracts, and active bacterial serum extracts showed that the untreated serum in bacterial extracts was the most active. Leucocyte-attracting properties apparently are not only confined to foreign proteins (bacterial proteins) but also to homologous proteins (even body proteins) denatured by coagulation. The proteins after contact with complement-containing body fluids showed an increase of leucotactic properties. This is believed to be due to the formation of leucotactic cleavage products from less active higher complexes brought about by thermolabile serum ferments. The leucotactic effect is said to be proportional to the leucocyte-attracting substances. The multilocular injection of uniform amounts of these substances, provided certain experimental conditions are maintained, does not stimulate the mobilization of leucocytes.

The relation which leucotactic substances bear to immunity and processes of inflammation in which leucocytes play a part are discussed.

Further researches on combined vaccines, A. CASTELLANI (*Reprinted in Jour. Trop. Med. and Hyg.* [London], 17 (1914), No. 21, pp. 326-333).—Work is reported with mixed vaccines which is said to be confirmatory of earlier results. The combined vaccines studied were typhoid, paratyphoid A, and paratyphoid B; cholera and plague; typhoid, paratyphoid A, paratyphoid B, plague, and cholera; typhoid and Malta fever; typhoid, paratyphoid B, paratyphoid A, and Malta fever; typhoid, paratyphoid A, paratyphoid B, *Bacillus columbensis*, and *B. asiaticus*; typhoid, paratyphoid A, paratyphoid B, *Micrococcus melitensis*, *B. columbensis*, and *B. asiaticus*; dysentery, typhoid, and paratyphoid; and cholera, plague, typhoid, paratyphoid A, paratyphoid B, and Malta fever.

The use of combined vaccines made from carbolized emulsions of agar cultures in normal salt solutions which are not heated is deemed feasible, and when given to man the reaction is not severe and is less painful than when the bacteria are killed by heat. "The individuals inoculated with the above-mentioned combined vaccines generally produce agglutinins for each species of bacteria, and the amount for each species is not much less than control individuals inoculated with simple 'one disease' vaccines. The only exception, though only to a certain extent, seems to have been in the case of the typhoid-dysentery vaccines. Combined vaccines, when efficient, are of practical advantage, saving a great deal of time and rendering possible a contemporaneous vaccination for several different maladies."

The theoretical principles of employing specifically standardized ferments as a therapeutic measure, E. ABDERHALDEN (*Fermentforsch.*, 1 (1915), No. 2, pp. 99-104).—It is found that tumor-bearing animals treated with the serum taken from a healthy animal pretreated parentally with tumor substratum will show a marked improvement and a recession of the tumorous growth. This principle is being tested with other diseases.

Serum reaction in pregnancy and cancer by the coagulation method, W. W. KING (*Jour. Obstet. and Gynecol. British Empire*, 24 (1913), No. 6, pp. 296-303; *abs. in Jour. Amer. Med. Assoc.*, 62 (1914), No. 8, p. 650).—The serum from pregnant subjects was tested against various tissues. Albumin obtained from the urine of a pregnant subject was not digested by the serum from that subject, but was decomposed by the serum of three other pregnant subjects.

"Carcinoma tissue was obtained from a case of advanced carcinoma of the cervix, and both this and the albumin were prepared exactly in the same way as the placental albumin. Out of 9 pregnant sera, 6 digested other albumins besides placenta, thus demonstrating that the ferments of pregnancy are not limited in their power of digesting albumin. Of 8 cases of malignant disease, 3 digested placental tissue. These 3 cases included one of sarcoma of the knee. . . . Urinary albumin was not digested by this serum, though a case of epithelioma of the tongue reacted strongly to it. Three sarcomas were negative to carcinoma tissue. Thus out of 17 cases of pregnancy and malignant disease, 9 sera digested albumins of a different type from that against which, *ex hypothesi*, they were produced."

If these observations are accurate, therefore, the ferments are not specific.

Bacterial vaccines—their use and abuse, A. T. FERGUSON (*Amer. Vet. Rev.*, 46 (1915), No. 4, pp. 437, 438).—The author deplors the fact that vaccines are used by the laity.

Autolactotherapy. A new system of therapeutics, C. H. DUNCAN (*Amer. Vet. Rev.*, 46 (1915), No. 5, pp. 510-525).—This method depends on the immunization of the child through the agency of the mother's milk. The subject may also be immunized by drinking the milk of animals immunized with the micro-

organisms and possibly against plant poisons, such as poison ivy. The value of the method for protecting a community against typhoid infection is pointed out.

Studies on changes in the degree of oxidation of arsenic in arsenical dipping baths, R. M. CHAPIN (*U. S. Dept. Agr. Bul. 259 (1915), pp. 12, figs. 2*).—This bulletin reports upon field and laboratory experiments which have been briefly summarized as follows:

"All used arsenical dipping baths may be expected to contain (a) oxidizing organisms which work slowly, but steadily and persistently, and (b) reducing organisms which work very rapidly at times, but spasmodically. The reducing organisms exert an appreciable effect only in vats which are used at frequent intervals for dipping large numbers of cattle. The ordinary vat, used once a fortnight, is likely to show only a slow, steadily progressing oxidation of the arsenic, and periodical analyses or tests must be made if proper dipping strength is to be maintained.

"Formaldehyde solution (37 per cent), used in the proportion of 1 gal. to every 1,500 gal. (8.5 fluid ounces to 100 gal.) of liquid introduced into the vat, appears a safe and effective means for reducing oxidation to a low figure. But since there seems to be no evidence that under ordinary conditions oxidation is ever likely to progress so far as to result in the use of baths injurious to cattle, the question of the use of formaldehyde is purely economic. The writer believes that in most cases it will be cheaper to let some of the arsenic go to waste through oxidation. When the cost of a gallon of formaldehyde about equals the cost of all the materials necessary to make 500 gal. of dipping bath, there will probably be little financial gain either way, while there may be some real profit in its use through saving of labor in preparing [the] dip and through the reduction of offensive odor from the bath by keeping it under antiseptic conditions."

Contribution to the study of "marginal points" of the blood of mammals, A. LAVERAN and G. FRANCHINI (*Bul. Soc. Path. Exot., 7 (1914), No. 7, pp. 580-584*).—This is in large part a review of the subject with references to the literature.

The protection of parasites in the digestive tract against the action of the digestive enzymes, W. E. and E. L. BURGE (*Jour. Parasitology, 1 (1915), No. 4, pp. 179-183, figs. 3*).—"Tapeworms and roundworms from the intestine of the dog are not digested when introduced into activated pancreatic juice so long as they remain alive, but are digested when dead. If any part of them be killed this part is digested. A dead roundworm which is ordinarily digested when introduced into activated pancreatic juice can be prevented from being digested by keeping the dead body wall constantly permeated with nascent oxygen. The oxidative processes of the living parasites enable them to withstand the action of the digestive juices by oxidizing the enzym solution immediately in contact with them."

Experimental drug treatment of East Coast fever of cattle, G. H. F. NUTTALL (*Parasitology, 8 (1915), No. 1, pp. 56-87, fig. 1*).—The experiments here reported have been summarized by the author as follows:

"No drug has been found which will influence the fatal course of East Coast fever or retard the multiplication of *Theileria parva* in the blood of the affected cattle. The drugs which were tried with negative results were trypan-blue, Congo red, tryposafrol, creosote and oleum copaivæ, arsacetin, soamin, 606, emetin hydrochlorid, mercury salicylate, mercury succinimid, quinin bihydrochlorid and hydrochlorid, ethylhydrocuprein, ammonium fluorid, potassium iodid, sodium salicylate, calcium lactate, and nuclein.

"All of our animals died, 18 treated and 3 untreated, and showed typical lesions at autopsy. They were all infected by means of ticks (*Rhipicephalus appendiculatus*) which had fed on infected cattle as larvæ and nymphs and been placed on the experimental animals as nymphs and adults, respectively.

"The increase in the number of parasitized red blood corpuscles, but for slight irregularities, proceeds continuously night and day until the animal dies. We have not as yet observed a case ending in recovery."

A table is included which gives a summary of data relating to each experimental animal, except one, the number and kind of ticks which produced infection, the incubation period, the time when the parasites appeared in the peripheral blood, the time when the animals died, and the maximum percentage of parasitized blood corpuscles observed during the course of the disease.

The serological detection of glanders in asses and mules, SCHÜTZ and O. WALDMANN (*Arch. Wiss. u. Prakt. Tierheilk.*, 40 (1914), No. 6, pp. 503-515).—The sera of healthy asses and mules contain anticomplementary substances which make difficult the diagnosis of glanders in such animals with the usual complement fixation test. The agglutination values of all of the animal sera were low, which indicates the absence of glanders, save that it is well known that old chronic cases of glanders also have a low titer. By changing the hemolytic system so that it consists of horse serum complement, inactivated bovine serum as amboceptor, and red blood corpuscles of the guinea pig better results can be obtained.

From the results of an infection experiment it was found that the formation of specific antibodies took place in asses and mules from the sixth day on and reached considerable height during the course of the disease. With the complement deviation procedure a stronger fixation can be noted on the eight or ninth day post infection, which points to the formation of specific antibodies in the blood of asses and mules. The presence of specific deviating substances in the blood of these animals can be detected with certainty by the modified complement fixation test.

Some tests with the modified method were also conducted with the sera of horses and asses suspected of being infected with glanders. The serum of horses, contrary to that of asses and mules, contains no anticomplementary substances and can be adsorbed by guinea pig serum. The phylogenetic importance of this finding is pointed out.

About the reaction of mallein on sound horses and the significance of the conglutination reaction for diagnosing glanders, W. PFEILER and G. WEBER (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 15 (1914), No. 3-4, pp. 209-227).—The authors examined daily the sera of horses coming into Germany from Russia, where the subcutaneous mallein test is employed, and studied the effect of malleinization upon the outcome of a subsequent conglutination test.

Sound horses treated subcutaneously or conjunctivally with dried mallein after the fifth day showed an increase in the agglutination. In the horses tested by the conjunctival route the increase in agglutination titer was only 100 units. The agglutinants gradually disappeared in the animals so treated, but at various times. Complement deviating substances were found in three out of six horses after five days (malleinization) and on the sixth day they were markedly present. Eight days were required in one case for the appearance of complement-fixing substances. The complement-fixing substances vanished a few days after their appearance.

A previous ophthalmic test had no influence upon the outcome of a serum test. Conglutinating substances appeared much later than complement-fixing substances when mallein was instilled in the eye, so that the conglutination test can not be used for diagnosing the disease in its first stages. The

conglutinin-fixing bodies, however, remain much longer in the blood stream than the complement-fixing bodies, and from this standpoint the method should be employed where an absolute diagnosis of glanders is desired.

The advantage of using larger amounts of extract in conducting the complement fixation test for diagnosing glanders, ECKERT (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1914), No. 4, pp. 298-305; *abs. in Berlin. Tierärztl. Wehnschr.* 30 (1914), No. 33, p. 602).—As a rule, in this method a 1 per cent glanders bacillary extract is used, but it has been observed in some cases that the use of a solution of this strength declared horses free of glanders which, on clinical examination or on autopsy, were found to be affected with the disease. When an extract of 5 per cent was used for each 0.2 cc. of serum, the sera of many of the horses which did not react with the lower concentration indicated that glanders might be present. The highest bacillary extract concentration recommended by the author is 10 per cent.

Studies in the immunity to tubercular disease.—I, The caseation of the tissues, C. C. TWORT (*Vet. Jour.*, 70 (1914), No. 473, pp. 543-551).—This article discusses "what takes place in the presence of the tubercle or other bacilli producing caseation, and, on the other hand, what takes place in the presence of Johne's bacillus.

"In the case of the tubercle bacillus, the soluble toxin secreted probably does not act detrimentally on the surrounding cells, but may even act as a stimulant, so that phagocytosis of the bacilli is in no way interfered with. This toxin may have an influence in causing encapsulation of the diseased area, and thus more or less isolation from the other tissues of the body. Meanwhile the bacilli, both intra- and extra-cellular, but especially the former, commence to be disintegrated to the humors of the host. The products of this disintegration lead to a further fabrication of the specific lysin, while at the same time, if it becomes too great in amount, the animal cells are unable to survive, as the intermediate products of the breaking down of proteids are intensely toxic for the cells of the animal body. The increase of the specific lysin leads to further destruction of the bacilli, and this in turn to the liberation of more endotoxins, so that ultimately the cells inside the nodule are doomed to destruction. Thus the cells and bacilli within the constricted area react upon one another, and both in the end are killed out, the edges of the nodule, where the accumulated toxins can more easily be got rid of, being the only situation in which intact cells and bacilli can be found. Bacilli, apparently normal, may be found in the center of the caseous mass, but rarely any intact cells; and it is quite probable that many of the bacilli here found are really dead.

"In Johne's disease it is highly probable that little or no soluble toxins are produced, and the bacilli, although actively phagocytosed, are not toxic for the cells, and can live and multiply within them. At the same time, if a certain number of bacilli die or are killed by the host, the products of disintegration are better able to get away than in tubercular disease, as the lesions are never encapsulated, but blend more or less imperceptibly with the normal tissues. In leprosy the lesions are often encapsulated, but here again it is probably due to the nontoxicity of the bacilli for the cells, and especially on their ability to live and multiply within the cells, that there is an absence of caseation. The disintegration products of Johne's bacillus and the leprosy bacilli are as toxic for the animal as a whole, or locally for its tissues, as those of the tubercle bacillus. This is seen by the reaction produced on inoculation of a diagnostic vaccine on the one hand, and the effect produced by the inoculation of an emulsion of dead bacilli on the other, when with all three diseases, and with all three bacilli, the results are the same, that is to say, a rise of temperature in the first case and caseation of the tissues in the second."

Remarks on the work of Krautstrunk on tuberculosis protective vaccination tests with antiphymatol, M. KLIMMER (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 15 (1914), No. 2, pp. 169-175).—A discussion of the article previously noted (E. S. R., 29, p. 584).

The intradermal test in bovine tuberculosis, H. WELCH (*Montana Sta. Bul.* 105 (1915), pp. 351-380, figs. 20).—The subject of bovine tuberculosis in relation to public health and as a stockman's problem is first discussed and illustrations of tuberculous animals and pathologic tissues taken therefrom are shown.

The intradermal test was found equal in accuracy to the thermal test. The ordinary tuberculin produced by the Bureau of Animal Industry of the U. S. Department of Agriculture, for thermal testing, containing 5 per cent glycerol, was found preferable to any other kind for intradermal testing. In over 3,000 tests no swellings were observed that would be confusing.

"After an intradermal test, a retest of an infected animal in 6 to 8 days will give a distinct reaction. If several retests are made at similar intervals, the reaction becomes less and less characteristic with each injection of the tuberculin. . . .

"In applying the intradermal and the thermal tests at the same time, no appreciable effect is noticeable on the temperature curve but the size of the local reaction is somewhat modified. . . .

"When the cattle have been tested first by the thermal method, diseased animals frequently will not react to the intradermal test for at least 20 days, though the exact time has not been determined."

A large number of tuberculous animals will have to be tested and retested before an approximate time limit can be set for such a retest. It was also found that some animals react to the intradermal test but not to the thermal test. "Both tests applied simultaneously to a herd should, in the great majority of cases, pick out all the tuberculous animals."

In all, there were 4,055 intradermal tests on "2,635 cattle, there being 1,420 retests made by this method. One hundred and seventy-two cattle reacted; 169 of these were slaughtered and 168 were found tuberculous on post-mortem examination."

With calves typical reactions were obtained at four months of age, although it seems probable that the reaction would be typical in younger animals. In testing range cattle a corral or chute and some sort of a squeeze may be employed. "One man and a helper can test range cattle accurately at the rate of about 200 a day for an indefinite period. . . .

"The objection to the intradermal method as an official test [for interstate shipments], that is most frequently advanced, is that it leaves no record. As a matter of fact, it leaves more record on the cow than does the thermal test. . . . The intradermal test, in economy of time, labor, and expense, is preferable to the thermal test."

Studies on the biochemistry and chemotherapy of tuberculosis.—VIII, Therapeutic use of certain azo dyes in experimentally produced tuberculosis in guinea pigs, LYDIA M. DE WITT (*Jour. Infect. Diseases*, 14 (1914), No. 3, pp. 498-511).—A continuation of work previously noted (E. S. R., 30, p. 80; 31, p. 583).

"Trypanblue and trypanred readily penetrate the tubercle in all stages of its development, thus showing that it is possible to penetrate the avascular tubercle by chemicals introduced either subcutaneously, intravenously, or intraperitoneally. Trypanblue and trypanred do not penetrate the tubercle bacillus well, and do not kill it in vitro even after 24 hours' exposure to a

1 per cent solution. In therapeutic doses, frequently repeated for long periods, trypanblue and trypanred seem to have no favorable or curative influence in experimental tuberculosis in guinea pigs. In a single large, nearly lethal dose at the beginning of the infection they also have no favorable influence.

“Silver trypanblue and iron trypanblue also penetrate the tubercle, but have no bactericidal and no therapeutic influence. It is doubtful whether the metals are carried in with the dye. Copper trypanblue is soluble, but does not penetrate either the normal or the tuberculous tissues, and is probably changed to an insoluble form or a suspension colloid and retained at the point of injection. Mercury trypanblue is insoluble, is strongly bactericidal in its action on the tubercle bacillus, but is too toxic for therapeutic use, since the pigs died apparently from chronic mercury poisoning, rather than from the tuberculous infection, the tuberculous process being generally very slight. The findings with this salt, however, are suggestive, and further experiments with mercury salts will be made.”

Tuberculocidal action of certain chemical disinfectants: Studies of the biochemistry and chemotherapy of tuberculosis IX, LYDIA M. DE WITT and HOPE SHERMAN (*Jour. Infect. Diseases*, 15 (1914), No. 2, pp. 245-256).—Very little is in the literature in reference to the power of chemical substances to kill tubercle bacilli. It has generally been accepted that tubercle bacilli, though nonsporogenous, are the most resistant of pathogenic organisms.

“Phenol in 5 per cent water solution kills human tubercle bacilli in five minutes, one hour, six hours, and twenty-four hours. It is nearly as efficient in 1 per cent solution, and shows some tuberculocidal action down to 0.1 per cent solution. Formaldehyde in 1 per cent solution kills all tubercle bacilli in one hour (shorter time not tested). In 0.01 per cent solution it kills in twenty-four hours and so no disease develops in guinea pigs. Formaldehyde, therefore, is somewhat more efficient than phenol. Ethyl alcohol in 25 per cent solution kills all tubercle bacilli within one hour (shorter time not tried). Acetone, chloroform, and ether have very little, if any, tuberculocidal influence. Toluene and iodine show slight influence.

“Of the metallic salts used, mercuric chlorid shows the greatest tuberculocidal action, 0.001 per cent killing in twenty-four hours, and 0.1 per cent in one hour. Gold chlorid in 0.005 per cent solution kills in twenty-four hours, while 0.025 per cent silver nitrate kills in the same time. One-tenth per cent gold tricyanid and 5 per cent copper chlorid kill the organisms in twenty-four hours.

“From a comparison of the results of the experiments contained in this paper with those of disinfection work on other more rapidly growing organisms, the *Bacillus tuberculosis* appears less resistant than the streptococcus, staphylococcus, pneumococcus, or gonococcus, or than the *Bacillus typhosus*, *coli*, or *anthracis* spores, to phenol, formaldehyde, mercuric chlorid, silver nitrate and gold chlorid, but more resistant than these other organisms to alcohol, chloroform, ether, acetone, toluene, and Lugol's solution. The fat content of the tubercle bacillus does not determine its resistance to disinfectants. Our experiments seem to show that if the comparatively high content of this organism differentiates its behavior from that of bacteria of low fat content it does so by rendering the tubercle bacillus more resistant to fat solvents and less resistant to substances insoluble in fats.”

Coccidiosis in cattle and carabaos, C. H. SCHULTZ (*Jour. Infect. Diseases*, 17 (1915), No. 1, pp. 95-108).—A discussion of bovine coccidiosis and observations in the Philippines, where it apparently has an extensive distribution.

Hog cholera and methods of control, E. A. CAHILL (*Amer. Vet. Rev.*, 46 (1915), No. 4, pp. 417-424).—A discussion of the methods of preventing and treating cholera in hogs by serum and serum virus, and of the causes for failure.

The refractive index of serum from pigs immunized against hog cholera, E. PRONIEWICZ (*Abs. in Berlin. Tierärztl. Wehnschr.*, 30 (1914), No. 29, pp. 520, 521).—The refractive index of the sera of either normal pigs or of pigs hyper-immunized against hog cholera showed no characteristics which would enable one to detect the presence of hog cholera virus or antibodies.

Shall we adopt the use of hog cholera serum and virus as an immunizing and curative agent? S. J. MARQUARDT (*Amer. Vet. Rev.*, 46 (1915), No. 5, pp. 542, 543).—A plea for the discontinuance of virus in immunizing against hog cholera.

My experience with the simultaneous method of immunization, H. A. SMOTHERS (*Amer. Vet. Rev.*, 46 (1915), No. 6, pp. 621-625).—An account of some untoward results obtained by the serum simultaneous method.

The filterability of *Bacillus bronchisepticus*, with an argument for a uniform method of filtration, N. S. FERRY (*Jour. Path. and Bact.*, 19 (1915), No. 4, pp. 488-493; *abs. in Science, n. ser.*, 41 (1915), No. 1060, pp. 619, 620).—The author here reports a series of filtration experiments with *B. bronchisepticus*, which has been described as the cause of canine distemper. The work was carried on with a Berkefeld N and six Pasteur F candles that upon test showed no signs of leakage or weakness at any point and gave a very high efficiency as recorded by the pressure gauge.

"The results of the work proved conclusively, according to all rules as laid down by the several authorities on filterable viruses, that the *B. bronchisepticus* is a filterable organism. The work also corroborated the results of previous investigators with regard to the fact that the less pressure used the more easily will some organisms pass through the filters."

Is *Leucocytozoon anatis* the cause of a new disease in ducks? A. B. WICKWARE (*Parasitology*, 8 (1915), No. 1, pp. 17-21, pls. 3).—Numerous inquiries regarding an apparently infectious disease which appeared among ducks at Ottawa, Ontario, led to the investigations here reported. At a poultry farm on which the investigations were conducted young ducks were found dying at an average of 20 a day. The mortality was exceptionally high, being estimated at 65 to 70 per cent, and the young ducks that recovered remained undersized and stunted.

Examinations of the blood showed the presence of *L. anatis* in large numbers in the peripheral circulation of the ducks in which the affection ran an acute and fatal course. These protozoa gradually diminished in number in the ducks which made an apparent recovery, while in contact birds which presented no clinical manifestations parasites were not demonstrable. Attempts to transmit the disease failed.

The author found that until further experimental studies are undertaken no general conclusions should be drawn. The fact that this parasite was present in large numbers in all affected birds and absent in all the controls coming under observation is considered significant.

Poultry parasites: Some of the external parasites that infest domestic fowls, with suggestions for their control, G. W. HERRICK (*New York Cornell Sta. Circ.* 29 (1915), pp. 29-39, figs. 5).—This is a popular account of the commoner parasites of poultry and control measures, descriptions of which are given in the bulletin previously noted (*E. S. R.*, p. 353).

RURAL ENGINEERING.

The effect of the width of the channel of approach on the flow of water over weirs, W. F. MARTIN (*Cornell Civ. Engin.*, 23 (1915), No. 5, pp. 180-190, figs. 4).—“The object of this investigation was in part to supplement or continue the work of Bazin, who had conducted experiments on sharp crested weirs without end contractions, for the express purpose of determining the effect on the coefficient of discharge of the height of weir above the bottom of the channel of approach.

“Four distinct series were run on sharp crested weirs, without lateral or end contraction and having the same height of crest and same length of channel of approach, but with widths 2.023 ft., 0.5165 ft., 0.2597 ft., and 0.1296 ft. . . . The heads ranged from the lowest or zero up to 1.5 ft. except for the longest weir, in which case the maximum head was about 1 ft.

“It was found that the coefficient of discharge varies with the width of the channel of approach, the variation being very slow for the longer weirs and quite rapid for the very short weirs. As might be expected, there is a decrease in the coefficient of discharge. This effect probably ceases to be noticeable when the length of weir is three or four times as great as the maximum head on the weir.”

The relation of stream gaging to the science of hydraulics, C. H. PIERCE and R. W. DAVENPORT (*U. S. Geol. Survey, Water-Supply Paper 375-C* (1915), pp. 77-84, fig. 1).—A brief discussion of the development of hydraulics with reference to the measurement and computation of stream flow is given.

Artificial control sections for river measurement stations, J. C. HOYT (*Cornell Civ. Engin.*, 23 (1915), No. 5, pp. 176-179, figs. 3).—The author states that “the most successful control so far constructed consists of a low submerged dam, which in many places may be made on a reef or bar of gravel or bowlders by grouting with cement. In other places it may be necessary to excavate the bed and build a concrete structure or to drive sheet piling across the section nearly flush with the bottom. Such structures will tend to prevent scour and at the same time so limit the channel that the natural current reduces the probability of silting.”

Surface water supply of Pacific drainage basins in Washington and upper Columbia River basin, 1912 (*U. S. Geol. Survey, Water-Supply Paper 332-A* (1915), pp. VI+282, pls. 2).—This report, prepared in cooperation with the States of Montana, Idaho, and Washington, presents the results of measurements of flow made on the Quenilt River, Puget Sound, and upper Columbia River drainage basins during 1912.

Ground water in Paradise Valley, Arizona, O. E. MEINZER and A. J. ELLIS (*U. S. Geol. Survey, Water-Supply Paper 375-B* (1915), pp. 51-75, pls. 3, figs. 9).—This report deals with the ground-water supplies of an area covering about 200 square miles, which lies between the Phoenix and McDowell ranges of mountains and occupies a trough-like depression that has been partly filled by unconsolidated rock débris washed from the mountains.

“Paradise Valley is underlain by a deep deposit of detrital material, which in its lower part is saturated with water. . . . The water table . . . slopes southward at an average rate of about 5 ft. to the mile, which is much less than the slope of the land surface. Along the Arizona canal the depth to the water table is 50 ft., or slightly more; toward the north it increases as the land surface rises until along the abandoned Verde canal it is nearly 300 ft.” The ground water of the valley is supplied from the run-off and underflow of Cave Creek, the run-off from the mountain areas directly tributary to the

valley, and the rain that falls on the valley, and is nearly or wholly inclosed by impervious bed rock, except at the south end where there is underflow into the Salt River valley.

"There is no evidence of artesian structure in the valley fill nor in the surrounding bed rocks, and wells should be drilled with the understanding that pumping will be necessary. Except near the Arizona canal the ground water is of good quality for domestic and industrial uses and for irrigation. Even in the vicinity of the canal it is believed to be usable for irrigation. . . . Both the yield of wells and the ultimate supply of ground water will no doubt be found to be much less in Paradise Valley than in the Salt River valley, but the prospects for obtaining dependable supplies from underground sources for irrigation on a small scale are sufficiently encouraging to justify the sinking and testing of wells. On account of the great depths to the water table the cost of ground-water supplies will at best be high, but it is believed that if electric power is obtained at a low price, if crops are raised that are valuable and do not require very large quantities of water, such as long-staple cotton, and if thrift and good management are applied it will be practicable to pump the available supply of ground water for irrigation in the southern part of the valley."
